BOTANICAL ABSTRACTS

A monthly serial furnishing abstracts and citations of publications in the international field of botany in its broadest sense.

UNDER THE DIRECTION OF

THE BOARD OF CONTROL OF BOTANICAL ABSTRACTS, INC.

J. R. SCHRAMM, Editor-in-Chief
National Research Council, Washington, D. C.

Vol. 12

JANUARY, 1923

No. 1

ENTRIES 1-932

AGRONOMY

C. V. PIPER, *Editor*

MARY R. BURR, *Assistant Editor*

(See also in this issue Entries 136, 139, 179, 203, 210, 217, 285, 286, 301, 348, 409, 422, 482, 525, 664, 687, 698, 721, 762, 763, 766, 793, 815, 829, 836, 849, 852, 866, 878, 881, 888)

1. ANONYMOUS. Cycles in yield of crops. *Nature* 109: 261-262. 1922.—Editorial comment is made on publications by H. L. Moore and by Sir William Beveridge.—*O. A. Stevens.*

2. ANONYMOUS. El cultivo del arroz. [Rice culture.] *Rev. Soc. Rural Cordoba [Argentina]* 21: 5701-5709. 1921.—Rice culture is discussed including history, cultivation, varieties, and uses.—*John A. Stevenson.*

3. ANONYMOUS. El cultivo del lino. [Flax culture.] *Jalisco Rural [Mexico]* 4: 715-721. 5 fig. 1922.—The article recommends flax growing for Mexico and gives cultural directions.—*John A. Stevenson.*

4. ANONYMOUS. International potato conference. *Gard. Chron.* 70: 280-281. 1921.—In this conference, held at London, November 16, 17, and 18, the 1st session was devoted to breeding and selection. At subsequent sessions there were addresses on early history, industrial and commercial uses, degeneration, life history of wart disease organism, immunity, blight, and miscellaneous diseases of the potato. The papers and discussion are to be published in an official report. [See also *Bot. Absts.* 11, Entries 2849, 2853, 2889, 2899, 2916, 2920, 2922, 2923, 2960.]—*P. L. Ricker.*

5. ANONYMOUS. Main crop potatoes at Wisley 1921. *Jour. Roy. Hort. Soc.* 47: 90-94. 1922.—Eighty-five stocks of potatoes were grown. The awards of the committee are listed. A classified list of varieties with descriptions and notes is given.—*J. K. Shaw.*

6. ANONYMOUS. Phosphorsäuredüngung und Beschaffung. [Fertilizing with and securing phosphoric acid. *Mitteil. Deutsch. Landw. Ges.* 37: 395-402. 1922.—A discussion, led by GERLACH, is reported regarding the extent to which the use of phosphoric acid may be temporarily dispensed with and sources of supply.—*A. J. Pieters.*

7. ANONYMOUS. The 1920 wheat, oats and corn yields from soil experiment fields in Illinois. Illinois Agric. Exp. Sta. Circ. 246. 4 p. 1921.—The report covers results from a number of the University of Illinois soil experiment fields located in different parts of the state.—*Mary R. Burr.*

8. ANONYMOUS. Work of sugar experiment stations. Bundaberg field day. Australian Sugar Jour. 14: 140-141, 147-149. Fig. 2-5. 1922.—A brief description is given of the best of the varieties of sugar cane and of cane seedlings which are being tested at the farm. Shahjahanpur No. 10 is proving to be frost resistant. This Indian variety is thin in stalk but has been increasing in diameter since it has been growing in Queensland.—*C. Rumbold.*

9. ALMADA, PONCIANO R. El cultivo de la caña de azucar. [The cultivation of sugar cane.] Jalisco Rural [Mexico] 3: 281-284. 1920.—Popular.—*John A. Stevenson.*

10. ANDERSON, H. Aim and purpose of federal grain standards. Rept. Maryland Agric. Soc. 6: 240-242. 1921 [1922].—Federal grain standards have proved advantageous in marketing wheat. With definite standards, the prices paid to farmers are consistent with prices quoted at the nearest terminal markets. Certain tests perfected by the U. S. Department of Agriculture safeguard wheat shipments.—*A. Lee Schrader.*

11. AYRES, W. E. Cotton experiments 1921. Mississippi Agric. Exp. Sta. Circ. 42. 8 p., 2 fig. 1921.—The results of variety tests, spacing, and breeding are given with discussions on topping and time for thinning cotton.—*J. Fred O'Kelly.*

12. B[ARBER], G. A. The classification of sugar cane varieties. [Rev. of: EARLE, F. A. Sugar cane varieties of Porto Rico. II. Jour. Dept. Agric. Porto Rico 5³: 1921 (1922).] Internat. Sugar Jour. 24: 350-353. 1922.—The second review of this paper.—*C. Rumbold.*

13. B[ARBER], C. A. Recent work in cane agriculture. [Rev. of: Review of agricultural operations in India 1920-1921. Sugar cane. 9-14. Superintendent of Government Printing Calcutta, 1922.] Internat. Sugar Jour. 24: 361-362. 1922.—Promising results are being obtained with seedlings raised at the Coimbatore farm, especially those obtained by crossing thick canes with *Saccharum spontaneum*, a natural grass. Hybrids having the deep-rooting character of the wild grass and the sucrose content of the cane have proved suitable for North Bihar and parts of the Punjab. In the United Provinces M16 and J247 are suitable for intensive cultivation. In Bengal, Yellow Tanna proved good. In the Punjab, Saretha was best in the Canal Colonies and Bihar. Co205 headed the best at Gurdaspur farm. In Assam, Striped Mauritius, B147, B376, and J33a were distributed; of new varieties Co9 and D74 were the most promising. In the Central Provinces, Khari is replacing the local Katai and Kala and some of the Coimbatore seedlings are promising. In Burma, cane cultivation is increasing and the following varieties, introduced from Coimbatore, are successful:—Ashy Mauritius, B147, J247, and Gilman. In Mysore, seedling work is continuing, and 2 seedlings are mentioned as superior to Red Mauritius, which exceeds the output of the local cane, Pattapatti, by 25 per cent.—*C. Rumbold.*

14. BARTLETT, H. Farmers' experiment plots. Maize experiments, 1921-22. Western district. Agric. Gaz. New South Wales 33: 409-410. 1922.—Seed was sown in drills 6 feet apart with 3 grains every 3 feet in the drills. The highest yield of 35 bushels per acre was secured from Funk's Yellow Dent and the lowest yield, 17 bushels per acre, from North West Dent. The variety U. S. 133 had a stalk height of but 4 feet and yielded 34 bushels.—*L. R. Waldron.*

15. BASU, S. K. Green-manuring of broadcasted paddy in Orissa. Agric. Jour. India 16: 689-690. 1921.—Seeds of dhaincha (*Sesbania aculeata*) and paddy are sown together in the proportion by weight of 1 of dhaincha to 6 of paddy. A month or 6 weeks later the fields are

ploughed, the green manure crop (and most of the rice seedlings) being destroyed and buried and serving as manure for the surviving rice plants. Field trials showed an increase in yield of 290 pounds of paddy as a result of this method.—*A. Howard*.

16. BASU, S. K. The possibilities of rabi crops in Orissa. *Agric. Jour. India* 17: 92-94. 1922.—The frequent destruction by floods of the paddy crop over large areas in Orissa has led to experiments to find the best means of utilizing such areas during the succeeding cold weather. Good yields of wheat, barley, oats, gram, and peas were obtained.—*A. Howard*.

17. BAUR, C. Ist der Hafer mit sich selbst verträglich? [Should oats follow oats in crop rotation?] *Illustr. Landw. Zeitg.* 42: 115-116. 1922.—Experiments are reported which show that land planted in oats is unfavorable to oats for at least 3 years thereafter. As possible causes, "soil exhaustion," lack of calcium, toxic root excretions, and insect pests are discussed.—*John W. Roberts*.

18. BLAKELY, W. F. Another pest for wool-growers. *Agric. Gaz. New South Wales* 33: 447. 1922.—Attention is called to the recent introduction of *Cenchrus pauciflorus* into New South Wales.—*L. R. Waldron*.

19. BREAKWELL, E. The medics or burr trefoils. *Agric. Gaz. New South Wales* 33: 418-426. 2 fig. 1922.—An analytical key and descriptions are given of various species, including *Medicago lupulina*, *M. denticulata*, *M. minima*, *M. laciniata*, *M. maculata*, *M. truncatula*, *M. orbicularis*, *M. scutellata*, *M. reticulata*, and *M. tuberculata*. Three species of crow foot of economical value, *Erodium cygnorum*, *E. moschatum*, and *E. cicutarium*, are described.—*L. R. Waldron*.

20. BUIE, T. S. Cotton varieties. *Georgia Agric. Exp. Sta. Bull.* 136. 10 p. 1920.—Twenty-five varieties of cotton (*Gossypium herbaceum*) were tested. Histories of these varieties are given as well as cultural directions for use under boll weevil conditions.—*T. H. McHatton*.

21. BURT, B. C., and R. S. FINLOW. Some preliminary experiments with jute in the United Provinces. *Agric. Jour. India* 16: 618-625. 1921.—Trials show that on suitably selected land marketable jute can be grown profitably on the low-lying areas near the Sarda and Gogra rivers. Successful introduction of the crop depends largely on whether local cultivators can be persuaded to pay sufficient attention to proper cultivation and to retting.—*A. Howard*.

22. BUSSE, W. Ertragssteigerung bei Flachs durch Klimawechsel. [Increased yield of flax by change of climate.] [Rev. of: Commerce report of the Netherlands Government 9: 782.] *Mitteil. Deutsch. Landw. Ges.* 37: 386. 1922.—Flax seed of Irish growth was sent to Holland, France and Canada; seed was produced and returned to Ireland. The yield from the foreign raised seed of Irish origin was better than that from Irish grown seed.—*A. J. Pieters*.

23. C[ANADIAN] S[OCIETY OF] T[ECHNICAL] A[GRICULTURISTS] COMMITTEE ON RESEARCH. Agricultural research in Canada. *Sci. Agric.* 3: 3-17. 1922.—A list is presented of possible problems, including 53 in agronomy, 62 in botany and plant pathology, and 15 in horticulture.—*B. T. Dickson*.

24. CHILDS, R. R. A cotton production program. *Georgia State Coll. Agric. Bull.* 229. 12 p., 3 fig. 1921.—General information and instructions are presented to the farmers of Georgia in an effort to overcome the low price of cotton and boll weevil injury; suggested rotations are given, varieties recommended, and plans outlined for poisoning and controlling the weevil.—*T. H. McHatton*.

25. CHILDS, R. R. **College No. 1 cotton.** Georgia State Coll. Agric. Bull. 226. 8 p., 3 fig. 1921.—College No. 1 cotton is a new early variety of big boll cotton (*Gossypium herbaceum* L.) developed at the Georgia State College of Agriculture to meet the demands in the fight against the boll weevil. The variety originated as a selection from Sunbeam, the original work being done by R. J. H. DeLoach and the final selection being made by L. E. Rast in 1912. The variety comes from a single plant and the plant-to-the-row method has been followed in developing it. The variety is of vigorous growth with few vegetative branches; it is an early yielder and has averaged 885 pounds of lint cotton per acre in the experimental plats since 1914.—T. H. McHatton.

26. CHILDS, R. R. **Cotton production and boll weevil control.** Georgia State Coll. Agric. Bull. 238. 28 p., 15 fig. 1921.—The recommendations for cotton production under boll-weevil conditions include the production of home supplies, early planting and good care of the crop, and the use of calcium arsenate against the weevil.—T. H. McHatton.

27. CHILDS, R. R. **Seed selection on the farm.** Georgia State Coll. Agric. Bull. 241. 16 p., 9 fig. 1921.—Diagrams of seed plats and directions for selecting and improving various farm crops are given.—T. H. McHatton.

28. CLARK, S. P. **Rhodes grass in Arizona.** Arizona Agric. Exp. Sta. Circ. 36. 3 p. 1921.—Rhodes grass is valuable for pasture and hay fields on very alkaline soil. It withstands drought fairly well but a temperature below 15°F. is usually fatal. The average yield is 3-6 tons per acre.—Herbert C. Hanson.

29. CROSS, W. E. **Distancia a que se debe plantar la caña de azucar.** [Distance for planting sugar cane.] Rev. Indust. y Agric. Tucuman 11: 113-118. 1921.—Work to ascertain the best distance between rows of cane was begun in 1915 and carried on in 1920. The varieties used were P.O.J. 36, P.O.J. 213, Kavangire, and Zwinga. Plantings were made at distances of from 0.9 to 2.4 m., practically identical yields being obtained from all. The closer the rows, the more numerous but smaller in diameter were the stalks. The distance recommended for Tucuman depends upon the cultural methods employed. With hand work 2.4 m. is most economical, with machinery 1.8 or 2.0 m. Closely spaced rows with more stalks per row are more expensive to plant, cultivate, and harvest.—John A. Stevenson.

30. CROSS, W. E. **Estudios de la caña dejada dos años en pie.** [Studies of cane left standing two years.] Rev. Indust. y Agric. Tucuman 11: 85-99. 1920.—The 1919 cane crop of Tucuman was too large to harvest during the grinding season. The planters were confronted with the problem of cutting and burning the unharvested cane to permit a ratoon crop, or to risk souring and rotting of the cane if left over until the following season. Experimental studies were made with certain of the Javan seedling varieties and Kavangire. Under usual conditions it was found to be satisfactory to leave cane uncut until the 2nd year. Such cane contained more fiber than 1-year old cane and there was a slightly lower extraction. No difficulties were experienced with the juice in the mill. The cane should be worked up as soon as possible after cutting.—John A. Stevenson.

31. CROSS, W. E. **Las posibilidades de las cañas de Java en Luisiana.** [Possibilities of the Javan canes in Louisiana.] Rev. Indust. y Agric. Tucuman 11: 118-121. 1921.—The P.O.J. seedlings developed in Java are hybrids between the hardy Indian canes native of subtropical regions and the large tropical non-hardy Javan types. They are resistant to disease, cold, and other unfavorable conditions. Their introduction met the situation in Argentina when the native varieties failed. They are recommended for Louisiana where the cane growers are attempting to grow tropical varieties under subtropical conditions. The Javan canes are very resistant to the mosaic disease, and the author recommends their introduction even though they may carry the disease.—John A. Stevenson.

32. CROSS, W. E. Nuevos estudios sobre las cañas tucumanas de semillero. [New studies with Tucuman seedling canes.] Rev. Indust. y Agric. Tucuman 11: 57-62. 1920.—A continuation of work previously reported upon [Ibid. 9: 161-167] involving the 1919 seedlings (first ratoons) and 1920 seedlings. Determinations of Brix, sucrose, purity, glucose, and yield were made. Low-yielding varieties or those poor in sucrose were discarded. Observations as to relative resistance to freezing are also recorded.—*John A. Stevenson.*

33. CROSS, W. E. Un ejemplo de la resistencia de la caña de Java a las heladas. [An example of the resistance of the Javan canes to freezing.] Rev. Indust. y Agric. Tucuman 11: 103-105. 1921.—Sugar cane in Tucuman was subjected to 5 days of freezing weather in July. Native varieties spoiled very quickly but the Javan varieties P.O.J. 36, 213, 228, and 234, and Kavangire stood up well through September and October. Chemical tests showed a falling off in sucrose and purity with an increase in glucose content during November and December.—*John A. Stevenson.*

34. CULLARE, JAUME. El conreu de l'alfals. [Alfalfa culture.] Rev. Inst. Agric. Catalan de San Isidro 70: 45-47, 139-141, 153-156. 1921.—Popular.—*John A. Stevenson.*

35. CUNNINGHAM, W. S. Sudan grass versus alfalfa hay for dairy cows. Arizona Agric. Exp. Sta. Timely Hints for Farmers 139. 4 p. 1922.—The results of a single feeding experiment show that alfalfa produced more milk than did Sudan grass.—*Herbert C. Hanson.*

36. DAWE, M. T. Arghan—the mysterious fibre which hails from the unknown. Tropic. Life 18: 86. 1922.—The author reports the organization of an Arghan Company “for the purpose of obtaining supplies of Arghan plants from their native habitat in the wilds and transplanting these into organized areas in British Dominions in the East.” Dawe says that merchants who have received samples of Arghan fibre are unable to distinguish it from the Columbian pita fiber believed by botanists to be the product of *Ananas macrodontes* Morren, and a closely allied species or variety [see Bot. Absts. 8, Entry 1593]. It is intimated that the name Arghan is a camouflage intended to divert the hunt for this plant from South and Central America to the region of the Arghandab River in Afghanistan, and the author proposes 3 questions designed to bring out the truth in regard to Arghan.—*H. N. Vinall.*

37. DOBBS, A. C. The improvement of agriculture in Bihar. Agric. Jour. India 16: 138-141. 1921.—The author advocates the study of agriculture by Bihari students.—*A. Howard.*

38. EASTERBY, H. T. Sugar experiment bureau. Summary of 21 years' work. Australian Sugar Jour. 14: 284-286. 1922.—This 3rd paper gives a summary of fertilizer experiments with plant and ratoon crops of cane.—*C. Rumbold.*

39. ESTRADA, MARIO. Utilidad de las leguminosas en la agricultura. [Value of the legumes in agriculture.] Rev. Soc. Rural Cordoba [Argentina] 21: 5717-5728. 1921.—The value of leguminous plants as forage crops and nitrogen gatherers is discussed.—*John A. Stevenson.*

40. FAIN, JOHN R. Alfalfa for Georgia. Georgia State Coll. Agric. Bull. 217. 12 p. 1920.—Types of alfalfa (*Medicago sativa* L.), also soils, preparation of land, fertilizers, seeding, cultivation, cutting, as well as uses of this crop are discussed.—*T. H. McHatton.*

41. FAIN, JOHN R., and PAUL TABOR. Hay crops for Georgia. Georgia State Coll. Agric. Bull. 237. 20 p., 17 fig. 1921.—A general discussion is presented of 30 hay and forage crops adapted to Georgia with outline maps designating the sections especially suitable to the various plants.—*T. H. McHatton.*

42. FAULKNER, O. T. Tests of Punjab wheats Nos. 11 and 8A at Lyallpur 1915-20. *Agric. Jour. India* 16: 508-518. 1921.—These 2 varieties have been compared for 5 years on 170 pairs of plots and found to be very similar in yielding power. From the miller's point of view, Punjab 11 is considered preferable.—A. Howard.

43. FERRIS, E. B. Peanuts. *Mississippi Agric. Exp. Sta. Bull.* 208. 14 p. 1922.—This is a revision of Bull. 130. Varieties are described and the "White Spanish" is given as the best for south Mississippi. Soil requirements, preparation of land, fertilizers, cultivation, harvesting, yields, value as soil builders, and uses are discussed somewhat in detail. Tables are given comparing the feeding value of peanut hay with other hay crops, average composition of the food and fertilizing constituents in different parts of the plant.—J. Fred O'Kelly.

44. FINLOW, R. S. Historical note on experiments with jute in Bengal. *Agric. Jour. India* 16: 265-279. 1921.—A short chronological account is given of the investigations on jute (*Corchorus capsularis* and *C. olitorius*) in Bengal since 1904. Various races have been isolated by selection which yield more than the ordinary crop. Kakya Bombai, a strain of *C. capsularis*, outyields local races about 250 pounds of fiber per acre. Chinsurah green, a selection from *C. olitorius*, has also given good results under experimental farm conditions.—A. Howard.

45. GAVILÁN, JUAN. Nuevos metodos de cultivo de cereales en secano. [New methods of cultivating cereals under "dry-land" conditions.] *Información Agric.* [Madrid] 12: 97-100. 3 fig. 1922.—Greatly increased yields have been obtained by the use of machinery in cereal cultivation in Spain. This has made it possible to raise within the country a larger percentage of its necessary breadstuffs.—John A. Stevenson.

46. GUZMANES, ANTONIO. Fertilización de la remolacha azucarera, patatas, y maíz. [Fertilization of the sugar beet, the potato, and corn.] *Información Agric.* [Madrid] 12: 108-109. 2 fig. 1922.—Directions for fertilizers to secure maximum yields are given.—John A. Stevenson.

47. HANMANTE, N. V. Experience of prickly pear as an emergency cattle food. *Agric. Jour. India* 17: 389-391. 1922.—During the famine of 1920-21 demonstrations of the value of prickly pear as a fodder for work cattle were carried out in the Ahmedabad District in Bombay. Over 1,500 starving cattle were fed with prickly pear from which the thorns were previously removed by burning and to which 2 pounds of cotton seed and 2-3 pounds of dry grass for each animal were added. There was a rapid improvement on this diet and after 2 months the animals became vigorous.—A. Howard.

48. HANSEN, ALBERT A. Austrian field cress: A new weed in the United States. *Torreyia* 22: 73-77. Fig. 1. 1922.—In June 1921 *Roripa austriaca* Spach was found overrunning certain sections of Borderland Farm, New Milford, Orange County, New York. The plant was first introduced about 1910 in impure grass-seed and has spread by means of creeping roots until about 7 acres have become infested. It threatens to become a dangerous pest, and radical measures should be taken before it gets beyond control. It could probably be exterminated by spraying with iron or copper sulphate. Great loss can be prevented at very small cost if prompt action is taken.—J. C. Nelson.

49. HARSNBOWER, A. C. La alfalfa. *Bol. Camara Agric. Costa Rica* 1: 271-276. 1921.—Popular.—John A. Stevenson.

50. HAWKINS, R. S. Sudan grass in Arizona. *Arizona Agric. Exp. Sta. Circ.* 35. 5 p. 1921.—The author gives directions regarding the growing, harvesting, and uses of Sudan grass.—Herbert C. Hanson.

51. HENDERSON, J. W. Garlicky wheat. *Rept. Maryland Agric. Soc.* 6: 242-249. 1921 [1922].—Analyses of 462 samples of wheat secured in 21 out of 23 counties of Maryland show

that Maryland wheat is "garlicky" almost without exception. The presence of garlic bulbs in the wheat of 1921 caused an estimated loss of \$421,300 to the producer.—A. Lee Schrader.

52. ISHAQ, A. R. Rice cultivation in the Larkhana district, Sind (India). Bombay Presidency Dept. Agric. Bull. 99. 38 p., 1 map. 1920.—A preliminary study is reported of the Larkhana district, lying west of the Indus River. Soils, climate, and irrigation are briefly treated.—The cultivation of rice, of which 11 varieties are recognized by the trade, is discussed at length. Pests are not serious. Wheat or legumes frequently follow rice the same year.—Share land tenure, high land values, and scarcity of labor help to make the economic condition of the cultivators relatively good.—Robert L. Pendleton.

53. ITIÉ, GABRIEL. El cultivo del algodón en la comarca lagunera. [Cotton culture in the Laguna district.] Rev. Agric. [Mexico] 6: 255-262. 5 fig. 1921.—The article deals with the history and methods of cotton culture in the Laguna district of Mexico,—John A. Stevenson.

54. ITIÉ, GABRIEL. Una hierba dañina—el cardo. [The thistle, an injurious weed.] Rev. Agric. [Mexico] 7: 90-92. 3 fig. 1922.—The article concerns *Carduus* sp.—John A. Stevenson.

55. KELLOG, C. E. Feeding sorghum pomace as silage to cattle. Georgia State Coll. Agric. Bull. 221. 12 p., 3 fig. 1921.—Sorghum (*Sorghum vulgare* Pers. var. *saccharatum*) pomace makes good silage. Analysis yields the following percentages: water 73.5, ash 1.08, crude protein 1.14, crude fiber 7.82, nitrogen-free extract 14.74, and crude fat 0.66; it compares well with other silages and gave an average daily gain of 2.11 pounds on 80 steers averaging 840 pounds per head during a feeding period of 105.5 days. The ration used consisted of 36 pounds of sorghum pomace silage, 6.07 pounds of cotton seed meal, 5.4 pounds of cotton seed hulls, and a very small amount of molasses.—T. H. McHatton.

56. KENOYER, L. A. Retarded development of temperate cereal varieties under tropical conditions. Agric. Jour. India 16: 454-457. 1 fig. 1921.—Kanred wheat from Kansas grown at Allahabad, India, by the side of Pusa 12 remained in the vegetative state until harvest and then made feeble culms with small, badly-filled ears towards the end of the hot season.—A. Howard.

57. KERLE, W. D. Farmers' experiment plots. Potato experiments 1921-22. Upper north coast district. Agric. Gaz. New South Wales 33: 381-390. 3 fig. 1922.—Experiments were undertaken in cooperation with 8 farmers. Eighteen varieties of potatoes were under trial, including well known varieties such as Scottish Triumph, Satisfaction, Factor, Up-to-date, Early Rose, Carman No. 1, and Early Manistee. The maximum yield of 315 bushels per acre was secured from Early Manistee grown at Condong on the Tweed River. Scottish Triumph, Early Manistee, and Early Manhattan were among the higher yielding sorts. The crop was injured on some farms by late blight caused by *Phytophthora infestans*. In the manual trials a complete fertilizer gave highest yields. Trials were made with various sized seed tubers planted at different rates.—L. R. Waldron.

58. KIRJASSOFF, ALICE BALLANTINE. Formosa the beautiful. Nation. Geog. Mag. 37: 247-292. 69 fig. 1920.—Details are given of the production of tea and camphor.—W. M. Atwood.

59. KNIGHT, J. B. Prickly pear as a cattle food. Bombay Presidency Dept. Agric. Bull. 97. 63 p., 18 pl. 1920.—The prickly pear (*Opuntia elatior* Mill.) was introduced into India about 1800 A.D., and is now quite common as a weed in many parts of the Bombay Presidency. During various famines it has been tried as a cattle feed, but not until 1918-19 was it used on a large scale.—The author describes in detail the feed value of the plant, showing

that it contains a high percentage of water and is low in protein. This necessitates the feeding with it of concentrated feedstuffs. Methods of removing the spines mechanically and by means of burning with gasoline torches and blacksmiths' forges, and the relative merits of the various processes are described. Full instructions are given for operating large famine camps for saving cattle. It is believed that thornless cactus may become an important fodder reserve for adverse years.—A bibliography of 26 titles is given.—*Robert L. Pendleton.*

60. KOESLAG, J. D. *De pootgoedverwisselingsproeven met Eigenheimers van het Centraal Comité in 1920 en 1921.* [Exchange of seed experiments with Eigenheimer seed potatoes by the Central Committee in 1920 and 1921.] *Cultura* 34: 94–108. 1922.—The object of the experiments is to ascertain whether the variety produces yields of different quality when grown for more than 1 year in the same section. Seed potatoes of the same origin were planted in different localities of the Netherlands. Diseases appeared sooner in some localities than in others. The experiments will be continued for several years.—*J. C. Th. Uphof.*

61. KOTTUR, G. L. An improved type of cotton for the Dharwar-American tract. *Agric. Jour. India* 17: 347–352. 1922.—For 6 years a selection from Dharwar-American cotton, known as Gadag 1, has given a better yield of lint and a higher ginning percentage than the ordinary crop.—*A. Howard.*

62. KULKARNI, L. B. A discovery: *Andropogon purpureosericeus* and its importance in the improvement of grazing areas in the Bombay Deccan. *Agric. Jour. India* 16: 388–395. *Pl. 22.* 1921.—This indigenous fodder grass is suitable for poor land, grows quickly, and yields up to 5,000 pounds of fresh produce useful for silage. It is somewhat drought resistant and suppresses *A. contortus*, the dominant species on most of the poor land of the Bombay Deccan. Both in the fresh condition and when dry it is preferred by cattle to *A. contortus*.—*A. Howard.*

63. LEAKE, H. MARTIN. The bases of agricultural practice and economics in the United Provinces, India. *viii + 27 p.* W. Heffer & Sons: Cambridge, 1921.—The book, based on lectures delivered to the students of Cawnpore Agricultural College, attempts to state the fundamental problems of agriculture in India and the lines along which improvement is to be sought. The scope of the book is indicated by the section headings: origin of agriculture; basis of agricultural practice (environmental conditions and plant growth); basis of agricultural economics (land, ownership, capital, production, and markets); development of agricultural practice (improvement of crops and of methods of cultivation); and development of agricultural economics (cooperative effort, the role of land-owner, government, and money-lender in agricultural improvement, and the cattle problem). [See also Bot. Absts. 11. Entry 6.]—*Winfield Dudgeon.*

64. LEIDNER, R. Vorschläge zur Vereinfachung der technischen Durchführung von Feldversuchen. [Proposals for simplifying the technic of field experiments.] *Landw. Jahrb.* 54: 283–288. 1919.—The author discusses methods designed to increase the accuracy of the results and to lessen the labor involved in harvesting and recording the yields of experiment plots.—*H. S. Reed.*

65. LEWIS, A. C. Cotton variety tests 1920. *Georgia State Bd. Entomol. Circ.* 35. 4 p. 1921.—For south Georgia, Lewis 63 and Council Toole are recommended where wilt occurs; for north Georgia, Wanamaker-Cleveland, Toole, Cook's Improved, and College No. 1 are recommended.—*T. H. McHatton.*

66. LEWIS, A. C., and C. A. McLENDON. Cotton variety tests 1919. *Georgia State Bd. Entomol. Circ.* 29. 10 p. 1920.—Variety tests were conducted in 7 counties of the state with the following varieties: Lewis 63, Council-Toole, Petty-Toole, Dixie Improved, Covington-Toole, DeSoto, Dixie Triumph (South Carolina), Toole (Toole), Cook's Improved, Cook 307-6, College No. 1, Cleveland (Wanamaker and other strains), King, Bank Account, Broadwell,

Trice, Simpkins, Hooper, Meadows, Half and Half, Dillon, Poulnot, Modella, Dix-Affi, Webber No. 49, Express, Big Boll Express, and Meade. In south Georgia Lewis 63 and Council-Toole gave best results and in east and north Georgia the Wanamaker-Cleveland headed the list.—*T. H. McHatton*.

67. LORENZETTA, JOSÉ R. El cuidado de los alfalfares. [Care of alfalfa fields.] Rev. Soc. Rural Cordoba [Argentina] 21: 5902-5911. 1921.—Methods of maintaining alfalfa fields are discussed.—*John A. Stevenson*.

68. McCAULEY, C., and L. J. GREEN. Oat variety trials, 1921. Cowra experiment farm. Agric. Gaz. New South Wales 33: 411-413. 1922.—In the early planting trial Fulghum yielded best at 58 bushels per acre while in the late planting trial it stood 2nd and Wilga, a new variety, 1st at 54 bushels. Brief notes are given on a similar trial at Yanco.—*L. R. Waldron*.

69. McDIARMID, R. W. Elephant grass (*Pennisetum purpureum*) at Coonamble experiment farm. Agric. Gaz. New South Wales 33: 431. 1922.—Under irrigation Elephant grass did remarkably well.—*L. R. Waldron*.

70. McLEAN, K. Water hyacinth. A serious pest in Bengal. Agric. Jour. India 17: 23-40. Pl. 2-3. 1922.—The water hyacinth (*Eichornia crassipes*), first noticed in Bengal about 1898, has now become a serious pest in the Gangetic delta where it interferes with navigation and the cultivation of deep-water rice. High floods in 1917 were followed by a check in the spread of the pest during 1918 and 1919. Since then it has spread rapidly, particularly in rivers and channels where the current is feeble. The plant reproduces itself vegetatively in Bengal and sets only a few seeds. These the author so far has failed to germinate. Operations against the spread of the weed consist in making the weed into manure and converting it into ash which is several times richer in potash than wood ashes. Attempts to extract potassium chloride from the ash proved a commercial failure. A committee has been formed by the Bengal Government to enquire into the spread of this pest in Bengal and to suggest measures for its eradication.—*A. Howard*.

71. MAJUMDAR, U. M. A comparative study of some agricultural aspects of Gujarat and the Deccan. Poona Agric. Coll. Mag. 12: 124-127. 1921.—A statistical comparison is presented of the total crop production, the yields of the various crops, and the total population-sustaining powers of the 2 districts.—*Robert L. Pendleton*.

72. MANN, H. H., S. D. NAGPURKAR, G. S. KULKARNI, R. S. KASARGODE, S. R. PARANJPYE, and B. M. JOSHI. Investigations on potato cultivation in western India. Bombay Presidency Dept. Agric. Bull. 102. ii + 142 p., 9 pl. 1920.—Descriptions are given of the methods of potato culture near Poona, Mahabaleshwar, and Dharwar. Crops are raised in the summer or rainy season, and in the winter season. The seed rate is about 1,200 pounds per acre. About 5 tons of farm yard manure per acre are applied annually. It would be profitable to reinforce this with ammonium sulphate, potassium sulphate, and superphosphate. The main variety grown is of Italian origin, as when transportation is normal the annual seed potato supply comes from Italy. There are 3 local varieties raised in the hills; the yields are good. English or Indian seed potatoes raised in the higher mountains are not at all suitable for western India. Difficulties of using local potatoes for seed are: serious infection and unsuitability of village storage conditions and methods.—Potato storage demands thorough aeration and a maximum temperature of not over 90°F. otherwise "black heart," a physiological disease, causes heavy to complete loss. Data are given of a chemical study of changes in the "black heart" or "heat rot" disease. Sacking in bags, placed on end and separated, decreases the loss. In extremely hot weather moist canvas must be hung in the doorways.—Other serious pests are the potato moth (*Phthorimea operculella*), ring disease, and tambara disease. Less serious diseases are caused by *Fusarium* spp., *Rhizoctonia* sp., *Spongospora* sp., the potato stem borer (*Leucinodes orbonalis*), and occasionally the potato eel worm. Against the potato moth, fumigation with

petrol in masonry chambers is followed by sacking to keep out moths. The ring disease is very severe, causing 20–60 per cent decrease in yield. Within 5 years the disease can be reduced in a given area to a 1 per cent incidence by rigorous selection of seed. Local pure seed supplies will have to be maintained.—Plans of an improved potato storage warehouse are given.—*Robert L. Pendleton.*

73. MILLIGAN, S. Improved field for agricultural investigations. *Agric. Jour. India* 16: 244–250. 1921.—The need is discussed of a special organization of investigation to make practical use of the results of research work on soil and crops.—*A. Howard.*

74. MITRA, S. K. A method of rice selection in Assam. *Agric. Jour. India* 17: 240–241. 1922.—Simple methods of selecting the best ears for seed as practised by the cultivators in Assam are described.—*A. Howard.*

75. MITSCHERLICH, E. ALFRED. Ein Beitrag zur Technik des Sortenanbauversuches. [A contribution to the technique of variety-testing experiments.] *Landw. Jahrb.* 57: 191–201. 1922.—The author has previously [*Ibid.* 54: 742–745] suggested a method whereby the largest experimental error due to the diversity of the soil is eliminated. By determining the amount

of seed to be used by the formula $s = \frac{K \cdot 100g}{G}$ in which s = quantity of seed per hectare, K ,

100 = weight of individual seed g , and G germination, it was found that the crop yield is a function of the amount of seed used. In cereals, the quantity of seed to be used is increased to 140 kgm. per hectare,—for winter barley, 160,—the distance of sowing depending, however, on the germination of the seed and weight of 1000 grains. When it is feared, however, that too thick sowing may bring about lodging, particularly on rich soils, the amount of seed may be reduced without committing a great error to 120 and 140 kgm. respectively. Potatoes are planted at a distance of 50 × 60 cm.—*Selman A. Waksman.*

76. MITSCHERLICH, E. ALFRED. Feldversuche mit Kartoffeln. [Potato field trials.] *Landw. Jahrb.* 54: 703–745. 1919.—The size of the experimental plots is one of the main factors to be determined. In one experiment 5 varieties were used and the plots were laid out in 4 sizes varying from 3.6 to 237.6 square m.; to overcome soil variability each plot was replicated 4 times. In another experiment fertilizers containing either 1, 2, or all 3 essential elements were applied. The method of laying out the plots was the same as for the other experiments, excepting a variation in the size of the plots from 7.2 to 259.2 square m. The data show that a 50 square m. plot is sufficient for potato experiments. The questions of proper spacing and the size of the seed pieces were also investigated. The general conclusion was reached, based on statistically treated data, that the best distance is 35 × 40 cm. for a seed piece weighing 65 gm.; for smaller seed pieces closer planting is advocated. It is pointed out that under different climatic and soil conditions entirely different results may be obtained. As part of these field trials an experiment was carried out in which various potassium salts were applied on a soil poor in potassium. The results with potassium were considered inconclusive, not only as to yield, but also as to the starch content and dry weight of the tubers harvested. In the Appendix an example of the application of Peters formula, $V = \pm 0.8453 \frac{\Sigma (+v)}{\sqrt{n(n-1)}}$ is given. By means of this method the probable error of a single plot was reduced.—*F. F. Halma.*

77. MORRILL, A. W. Corn as a trap crop for the cotton bollworm. *Arizona Agric. Exp. Sta. Circ.* 30. 10 p. 1920.—The growing of corn and cowpeas to serve as a trap crop for the cotton bollworm is advocated. Vacant spaces and ditch banks offer favorable locations for the crop.—*Herbert C. Hanson.*

78. MÜNTER, F. Zum Mais- und Sonnenblumenanbau. [Culture of maize and sunflowers.] *Mitteil. Deutsch. Landw. Ges.* 37: 266–268. 1922.—A brief account is given of trials at Halle with several American and European varieties of maize and sunflowers.—*A. J. Pieters.*

79. NELSON, JAMES C. A new weed from Oregon. *Torrey* 22: 86-88. 1922.—*Salvia Aethiopsis* L. was found in 1920 growing in great abundance in a field of alfalfa near Lakeview, Lake County, Oregon. It is spreading rapidly and threatens to become a dangerous pest. This plant was supposed by Linnaeus to be identical with the "Aethiopsis" cited by classical authors as a plant of medicinal value. It seems to have been imported in alfalfa seed from Russia.—J. C. Nelson.

80. NEUMANN, O. Die Wintergerste. Ihre Kultur und ihre Verwendungsmöglichkeiten. [Winter barley. Its cultivation and possible uses.] *Landw. Hefte* 48: 5-36. 1921.—The cultivation of winter barley increased in Germany during and since the war. This increase was stimulated by the great decrease in the importation of nitrogenous feeds. The present area is sustained by the limited importation due to low purchasing power of German money and the lack of cheap supplies in Russia. In 1919, 137,000 hectares were seeded to winter barley. The winter barleys commonly cultivated are mostly varieties of the 6-row winter form long cultivated in Europe. The culture of winter barley spread into Germany from Holland; this was accompanied by selection which increased winter hardiness. Winter barley has been found to have many advantages. It yields well, starts growth before spring weeds, distributes labor to greater advantage, ripens early and permits late summer crops to follow. Winter barley is seeded between the last of August and the middle of September after root crops, early peas, green fodder, winter rye, or winter barley. A number of local strains have been produced by various breeders. Winter barley as produced in Germany is suitable for feed, for distilling, and in limited quantities mixed with summer 2-row barley can be used in brewing.—H. V. Harlan.

81. NOLTE, O. Düngungsversuche mit verschiedenen Phosphorsäuredüngern zu Zuckerrüben. [Various forms of phosphoric acid as fertilizing materials for sugar beets.] *Illustr. Landw. Zeitg.* 41: 463-464. 1921.—Conclusions are given resulting from experiments in which equal amounts of phosphoric acids were used in the forms of superphosphate, Thomas slag, "Rhenania" phosphate, and bone meal. The highest sugar contents were obtained from plats treated with Thomas slag and "Rhenania" phosphate, but the acid phosphate also gave excellent results. The results from bone meal were comparatively poor.—John W. Roberts.

82. OPITZ. Über Getreidesaatenanerkennung [Certification of seed grain.] *Mittel. Deutsch. Landw. Ges.* 37: 402-404. 1922.—The author discusses the points to be considered in making a field inspection. Specific and varietal genuineness and purity, and presence of weeds and diseases are discussed in detail.—A. J. Pieters.

83. PARR, A. E., and PUTTOO LAL. A valuable cattle fodder. *Agric. Jour. India* 16: 206-208. 1921.—Feeding experiments with baisurai (*Pluchea lanceolata*), a common deep-rooting weed of the hot season in the Agra Division, mixed with dry millet stalks gave better results with work cattle than a ration of millet stalks alone. The utilization of this weed would help to solve the shortage of fodder in this tract.—A. Howard.

84. PATEL, M. L. The connection between seed weight and lint weight in cotton. *Agric. Jour. India* 17: 204-205. 1922.—As in other types of cotton, an increase in the weight of lint per seed involves an increase in the weight of the seed in the herbaceous cottons of Gujarat.—A. Howard.

85. PATIL, P. C. Summary of the work done on Jalgaon farm (Bombay Presidency, India). *Bombay Presidency Dept. Agric. Bull.* 108. 11 + 33 p. 1921.—Data are largely in tabular form, and conclusions are frequently not stated.—The farm was established for producing pure seed of *neglectum roseum* cotton in quantity for distribution.—Meteorological records are included. Rainfall influences crop growth more by its distribution than by its quantity.—The yields of all the important crops are increasing due to the use of modern methods. Valuable local manures are castor cake, sheep folding, and night soil; a practical method of applying

the last is described.—Some attention has been devoted to experiments on manuring, green manuring, rotations, hybrid and selected cottons, and variety trials. Peanuts proved of special value in the rotations.—*Robert L. Pendleton.*

86. PATTERSON, H. J. Lessons learned from twenty years of fertilizer tests. Rept. Maryland Agric. Soc. 5: 336-340. 1920 [1921].—This paper summarizes the effects of fertilizers on yield, quality, color, maturity, and abundance of weeds. The time and method of application are also discussed.—*A. Lee Schrader.*

87. PORTER, JOHN. The spraying of cornfield weeds with sulphate of ammonia. Jour. Ministry Agric. Great Britian 28: 1109-1116. 1922.—Preliminary trials in spraying grain fields with sulphate of ammonia for weed control gave satisfactory results with charlock (*Sinapis arvensis* L.), wild white mustard (*S. alba* L.), ivy leaved speedwell (*Veronica hederifolia* L.), and sheep's sorrel (*Rumex acetosella* L.). The chemical was only partially effective for corn, buttercups (*Ranunculus arvensis* L., *R. repens*, and *R. acris*), dandelion (*Taraxacum Dens-leonis* Desf.), broad dock (*Rumex obtusifolius* L.), and common field thistle (*Carduus arvensis* Curt.), and almost ineffective for black mustard (*Sinapis nigra* L.), black bindweed (*Polygonum convolvulus* L.), and milk or sow thistle (*Sonchus arvensis* L.).—The spray fluid consisted of 2 cwt. of sulphate of ammonia dissolved in water and made up to 60 gallons. The sulphate of ammonia is not as effective or reliable as copper sulphate though where it is effective it has the added advantage of greatly stimulating the growth of the cereal crop through its value as a fertilizer.—*M. B. McKay.*

88. REGEL, C. VON. Heuanalysen von der Halbinsel Kola. [Analyses of hay from the Kola peninsula.] Landw. Jahrb. 54: 277-281. 1919.—This paper gives the results of botanical analyses of 8 samples of hay collected from fertilized and unfertilized meadows at 2 stations within the Arctic Circle. On the fertilized meadows *Poa pratensis* was the dominant species while on only 1 of the unfertilized meadows was there any considerable amount of this grass. *Vicia cracca* occurring in 2 samples is the only legume reported.—*A. J. Pieters.*

89. RICHARDSEN, A. Fruchtfolgen und statischer Versuch in der akademischen Gutswirtschaft Dikopshof. [Rotations and statistical studies at the academic estate Dikopshof.] Landw. Jahrb. 53: 109-165. 1919.—A series of rotation and fertilizer experiments started in 1904 are reported. Various fields were laid out, different rotations being followed in each with and without stable manure and artificial fertilizers. The statistical study covers 1906-13 and consists of a detailed report with tables giving yields of sugar beets, rye, wheat, red clover, vetch, and oats, with and without nitrogen, phosphoric acid, potash, and lime.—*A. J. Pieters.*

90. RICHTHOVEN, VON. Saatkartoffelbeizung. [Treating seed potatoes.] Mitteil. Deutsch. Landw. Ges. 37: 386-387. 1922.—The author gives a preliminary report on an experiment in treating seed potatoes with "Uspulum." The treatment did not injure the seed potatoes and appeared to result in stronger initial growth.—*A. J. Pieters.*

91. ROEMER, THEODOR. Der Feldversuch. [The field experiment.] Arbeit. Deutsch. Landw. Ges. 302. 69 p. 1920.—A critical study is reported of plot experiments, including the various factors, methods, sources of error, size, position and shape of plots, and number of replications. BAULE adds a supplement in which he discusses mathematically the question of average or probable variation.—*A. J. Pieters.*

92. ROSS, H. Field experiments with wheat, 1921. Wagga experiment farm. Agric. Gaz. New South Wales 33: 403-408. 1922.—A number of new varieties of wheat were tested in comparison with a few standard varieties. Hard Federation outyielded most of the new varieties. The remaining trials included a test of wheat varieties for hay with and without fertilizers and similar trials with oats. Algerian oats gave the best results. Notes on a barley trial are given.—*L. R. Waldron.*

93. ROSS, H. A. The production and utilization of manure on Illinois dairy farms. Illinois Agric. Exp. Sta. Bull. 240. 473-489. Fig. 1-3. 1922.—The discussion of the amount of manure recovered per animal unit, possible rates of applying, methods of utilizing, seasonal applications, and labor cost of hauling is based on detailed cost-accounting investigations conducted 1912-1919 on 87 farms.—O. H. Sears.

94. SAILLARD, EMILE. La teneur en chlore de la betterave à sucre pendant la végétation. [The chlorine content of the sugar beet during vegetation.] Ann. Sci. Agron. Française et Étrangère 38: 152-157. 1921.—The possibility of using ammonium chloride, a by-product from the manufacture of sodium carbonate by the Solvay process, as a nitrogenous fertilizer in place of ammonium sulphate or nitrate raised a question as to the effect on the growth of the sugar beet and the extraction of sugar. Analyses are reported showing the water, nitrogen, ash, and chloride content of different parts of the beet at 5 periods of growth. The petioles together with the principal vein of the leaves are shown to contain most of the chlorine, and in all cases the chlorine content increases as the season progresses.—A. B. Beaumont.

95. SANYAL, P. B. The plant *Carica Papaya* and its enzyme. Agric. Jour. India 16: 496-507. 1921.—The yield of crude papain during the rains at Pusa was 16-18 per cent of the juice. The sample contained a globulin, an albumin, albumoses in considerable quantity, and a milk-curdling ferment. The method of preparing the pure product from the latex is described.—A. Howard.

96. SARABIA, G.M.O. Elección de semilla de alfalfa. [Selection of alfalfa seed.] Bol. Soc. Agric. Norte [Chile] 11: 61-63. 1921.—Methods are outlined for selecting alfalfa seed to insure best yields.—John A. Stevenson.

97. SCHULTZ, E. F. La alfalfa comun y los tipos invernizos de alfalfa en Tucuman. [Common alfalfa and the winter types of alfalfa in Tucuman.] Rev. Indust. y Agric. Tucuman 12: 17-32. 4 fig. 1921.—The author stresses the importance of alfalfa as the standard forage crop of Tucuman. Alfalfa in Tucuman should be planted during the period March to May, when there is sufficient moisture for germination. The soil should be well prepared and inoculation with soil from an old field is desirable in new fields. Other crops should not be interplanted. *Cuscuta*, a bad pest, can be exterminated by cutting the crop on a hot day and removing the hay from the field. Alfalfa is of particular value in rotation with sugar cane. Since rain makes hay making difficult much of the time, the use of silos, either of the stack or pit type, is recommended. Peruvian is the best variety yet tried but export of the seed has been forbidden by the Peruvian government. A local strain, known as No. 3, has been developed in consequence and has all the advantages of the Peruvian.—John A. Stevenson.

98. SCHULTZ, E. F. La "Phalaris bulbosa" en la provincia de Tucuman. [Phalaris bulbosa in the province of Tucuman.] Rev. Indust. y Agric. Tucuman 11: 63-74. 9 fig. 1921.—*Phalaris bulbosa* has been extensively studied in Argentina, including 5 years' experimental work at the Tucuman experiment station. The grass does not compare in value with Peruvian alfalfa as a forage crop, the latter giving yields 2-4 times greater. When propagated by seed it is easily overrun by weeds, due to poor germination; and when propagated by division the cost is excessive. Yields are reduced by the low-growing habit of the plant and its failure to make growth during fall and winter. The use of the grass is recommended only on sites where the water table is so close to the surface that the alfalfa roots rot.—John A. Stevenson.

99. SCHULTZ, E. F. Notas adicionales sobre la grama Rhodes. [Additional notes on Rhodes grass.] Rev. Indust. y Agric. Tucuman 11: 141-152. 5 fig. 1921.—Grazing experiments showed that Rhodes grass (*Chloris gayana*) is very resistant to freezing as well as to heat and trampling by stock. Cattle eat even the frozen material. The grass may be pastured close without injury and makes new growth in August when other pasturage is lacking. The shallow growing rhizomes permit of easy eradication by discing. It is not poisonous at any

stage of its growth. Stock pastured on this grass made satisfactory growth and produced meat of high quality. The grass seeds freely. Plantings should be made in the warm, rainy season to insure best stands, although success has been obtained at all seasons.—*John A. Stevenson.*

100. SHOWALTER, WILLIAM JOSEPH. Cuba,—the sugar mill of the Antilles. Nation. Geog. Mag. 38: 1-33. 24 fig. 1920.—Included in the description of Cuba is a discussion of the sugar and tobacco production of the island.—*W. M. Atwood.*

101. SMITH, F. H., and T. S. BUIE. Cotton fertilization experiments—1920. Georgia Agric. Exp. Sta. Bull. 137. 10 p., 1 fig. 1920.—Four types of raw phosphate were compared as sources of phosphorus for cotton (*Gossypium herbaceum*); none proving definitely superior. Indications are that raw ground phosphate may furnish some phosphorus during the 1st season; 2 successive applications give yields comparable to those with acid phosphate. Better yields were obtained when the raw phosphate was composted before using. Early applications of top dressings are advisable. On neutral soil, lime applications did not increase the yield. On heavy clay soils potash does not seem necessary; on sandy lands it is applied with profit. A 5-year test shows that on rich lands the rate of increase in cotton production is greatest for the first 200 pounds and that when complete fertilizers are applied the rate of increase in yield remained constant for applications heavier than 400 pounds per acre.—*T. H. McHatton.*

102. SNIDER, H. J. Recent crop yields from soil experiment fields in Illinois. Illinois Agric. Exp. Sta. Bull. 260. 8 p. 1922.—This circular presents in tabular form yields of wheat, corn, and oats obtained on a number of soil experiment fields located in different parts of the state. The figures cover a period of from 3 to 5 years, according to the duration of the rotation, in all cases ending with 1921.—*Mary R. Burr.*

103. SOULE, ANDREW M. Some factors affecting the economic production of cotton. Georgia State Coll. Agric. Bull. 247. 16 p., 5 fig. 1922.—The South is said to be losing its control of the world's cotton.—*T. H. McHatton.*

104. STAPLEDON, R. G. Germination of indigenous grass and clover seeds. Jour. Ministry Agric. Great Britain 29: 118-125. 1922.—Comparisons are made of the germinating capacity and other characteristics of seed collected from plants growing in their natural habitats with seed "once grown" at Aberystwyth and with ordinary commercial samples. The seed of indigenous species collected from various habitats tends to be of poor germinating capacity due in part to insects and in part to the difficulty of harvesting large quantities of seed under suitable and similar conditions. "Once grown" seed appears to be less attacked by insects and to germinate more satisfactorily. The precise value of "once grown" bulk-collected seed of such important grasses as perennial rye grass, cocksfoot, timothy, meadow foxtail, and others can only be determined by further investigation. It would seem from the results with wild white clover that reasonably good results may be expected from the inclusion of such "once grown" seed in mixtures designed for the preparation of long duration and permanent grass. The trials so far conducted at Aberystwyth tend to show that indigenous cocksfoot, rye grass, and timothy, for instance, have important qualities for long-duration pastures and are undoubtedly more persistent than their commercial counterparts.—*M. B. McKay.*

105. STAPLEDON, R. G. The growing and marketing of improved strains of herbage plants. Sci. Agric. 2: 405-408. 1922.—This address by the director of the plant breeding station at Aberystwyth, Wales, before the 1922 convention of the Canadian Society of Technical Agriculturists deals with work on clovers and grasses.—*B. T. Dickson.*

106. STEWART, ROBERT. The Illinois system of permanent soil fertility as developed by Cyril G. Hopkins. Illinois Agric. Exp. Sta. Circ. 245. 20 p., 14 fig. 1920.—In this address

before the Ohio Agricultural Experiment Station the basic principals of the Illinois system of permanent agriculture are discussed.—O. H. Sears.

107. TABOR, PAUL. Peanuts for the Piedmont section of Georgia Georgia State Coll. Agric. Bull. 249. 4 p., 1 fig. 1922.—A general discussion is presented of the preparation, cultivation, and harvesting of peanuts (*Arachis hypogaea* L.).—T. H. McHatton.

108. TAYLOR, C. SOMERS. Experiments with castor seed conducted at Sabour. Agric. Jour. India 16: 146-151. 1921.—Experiments have been made to determine whether by chemical selection it is possible to improve the castor oil plant (*Ricinus communis* L.). The mean oil content of the types grown at Sabour was 49.5 per cent. In the majority of cases the parent plants did not transmit a high or low oil-yielding tendency but in nearly every instance yielded seed with the oil content near the mean when the plants were healthy and a little lower when the reverse was the case. The author concludes that variations in agricultural treatment may have more effect on the oil yield of the crop than actual chemical selection.—A. Howard.

109. THOMPSON, G. E. Hegari in Arizona. Arizona Agric. Exp. Sta. Circ. 33. 4 p. 1921.—Hegari, a sorghum resembling kafir in appearance, is especially valuable in southern Arizona because it matures in about 110 days. It can be planted as late as early July, after the wheat harvest, and still mature before frost. It is used for grain, fodder, and silage.—Herbert C. Hanson.

110. THOMPSON, O. A. Edgeley substation report. Year ending June 30, 1921. North Dakota Agric. Exp. Sta. Bull. 161. 8 p. 1922.—1921 yields of wheat, oats, and barley secured from summer tillage plats were materially greater than for continuous tillage plats. Likewise wheat and oats following fallow in rotations outyielded these crops following small grains in rotations. In comparison with similar unmanured plats wheat and oats on manured fallow land showed decreased yields due to lodging. Oats after clover gave largest yield in comparison with oats after brome grass, alfalfa, and small grains. Early fall plowing showed some superiority to late fall plowing or to spring plowing. Wheat on disced corn land outyielded wheat on plowed corn land. Durum wheats outyielded all other varieties. The largest yields were secured from the rust-resistant durums, Monad, Acme, and D-5. The highest yielding varieties of oats and barley were Big Four and Manchuria respectively.—L. R. Waldron.

111. THOMPSTONE, E. Agriculture in the Shan States with special reference to the system known as "taungya" cultivation. Agric. Jour. India 16: 251-264, 396-405. 1921.—The Shan States lie between Burma and China and consist of an irregular plateau, about 3000 feet high, made up of well-wooded, grassy, upland plains and of open, treeless, rolling downs. The average annual rainfall is about 60 inches. The ordinary system of agriculture is known as taungya and consists in cutting down the jungle and firing it during the dry season, February-May. After this a variety of crops are grown,—hill rice, maize, potatoes, sesame, ginger, groundnuts, sweet potatoes, gourds, opium, cotton, and beans. The land is cultivated 1-3 years and then allowed to lie fallow for 4-15 years. Experiments have been conducted for some years to ascertain the best method of bringing these areas into permanent cultivation. Promising results were obtained by the use of lime and organic and green manures. The author concludes that by these means, combined with good cultivation and rotation of crops, continuous cultivation would be much more profitable than the present method of shifting from place to place.—A. Howard.

112. TROWBRIDGE, P. F. Report of the director, year ending June 30, 1921. North Dakota Agric. Exp. Sta. Bull. 159. 8 p., 2 fig. 1922.—For a 4-year average, wheat after clover yielded 22.2 bushels per acre, after potatoes 20.5 bushels, and after corn 20.4 bushels, on unmanured land. In a 9-year trial, stable manure increased wheat yields 2.6 bushels per acre or 12.5 per cent. In a 9-year period manure increased the yield of fodder-corn 527 pounds

per acre, or 8.5 per cent. Phosphatic fertilizers supplementing stable manure have increased yields of wheat less than 1 bushel per acre. Barley as a nurse-crop for sweet clover (*Melilotus alba*) tends to decrease seed production the 2nd year. In 1920 Assiniboine corn matured in 109 days and Minnesota 13 in 125 days.—*L. R. Waldron*.

113. VAGHOLKAR, B. P. Some observations on crude night-soil as manure to cotton in East Khandesh. Poona Agric. Coll. Mag. 12: 113-116. 1921.—“The rate and time of applying are the two most important factors that should be taken into consideration in using this manure for cotton.” In this part of India it should be applied before April. Judicious use has doubled the cotton yield for the year of application; the residual effect is small.—*Robert L. Pendleton*.

114. WALKER, G. B. Alfalfa in the Delta. Mississippi Agric. Exp. Sta. Bull. 209. 14 p., 4 fig. 1921.—The author discusses soils suited to alfalfa; preparation of seed bed; time, rate, and method of planting; inoculation; and time of cutting. Results of variety and fertilizer tests are given. Alfalfa as a pasture crop; alfalfa for coco-infested lands; getting grass out of alfalfa; and alfalfa in the crop rotation are each briefly discussed.—*J. Fred O’Kelly*.

115. WARD, F. C. Meade cotton. Georgia State Coll. Agric. Bull. 224. 4 p., 2 fig. 1921.—Meade cotton (probably *Gossypium herbaceum* × *G. barbadense*) is an upland, long-staple cotton that may be used to take the place of Sea Island cotton under boll weevil conditions; 4,000 acres of this variety were grown in Georgia in 1920. The standard length of staple set by the Government is 1½ inches and every effort should be made to maintain this length.—*T. H. McHatton*.

116. WARREN, D. C., and IRA W. WILLIAMS. Cotton dusting experiments of 1920—with recommendations for cotton dusting for coming season. Georgia State Bd. Entomol. Bull. 59. 15 p. 1921.—Dust applied while dew is on plants gives best results. The great fluctuation in cotton prices prevented any definite conclusions as to economic use of dust.—*T. H. McHatton*.

117. WARREN, D. C., and IRA W. WILLIAMS. Results of cotton dusting experiments for 1921 together with summary of the dusting results for past three years—with recommendations for cotton dusting for coming season. Georgia State Bd. Entomol. Bull. 62. 10 p. 1922.—The summary of the 3 years’ work in dusting with calcium arsenate against cotton boll weevil show an average gain of 206 pounds of cotton for short staple upland and 159 pounds gain on Sea Island cotton; 100 pounds of cotton pay for the dusting of an acre. Observations also show that the weevils not only get the poison from the dew but in other ways as well. Directions are given for dusting.—*T. H. McHatton*.

118. WESTBROOK, E. C. The tobacco plant bed. Georgia State Coll. Agric. Bull. 222. 8 p. 1920.—The author discusses and describes the preparation, care, and handling of tobacco (*Nicotiana tabacum* L.). Instructions for preparation of soils, use of fertilizers, and setting the plants in the field are also given.—*T. H. McHatton*.

119. WOODWARD, JOHN. Sulphur as a factor in soil fertility. Bot. Gaz. 73: 81-109. 1922.—A summary is given of work on the relation of soil sulphur to productivity. Field experiments were conducted with gypsum in Indiana and Kentucky. Soil analyses were made of soils from Indiana, Kentucky, Michigan, Ohio, and Wisconsin. “The analytical data show a general relation between the sulphur content and loss on ignition in soil samples from the same or closely related soil types, but the relation is not apparent when different soil types are compared. The sulphur contents of the surface soil vary from 0.0118 to 0.0905 per cent. All of the upland soils and most of the alluvial soils are low in sulphur.” The author finds that the highest sulphur content is sufficient for 39 years of alfalfa, 139 of clover, 159 of timothy, 355 of wheat, or 232 of corn. Though not quantitative, the field experiments indicate that tobacco, clover, and alfalfa have been benefited by the use of gypsum.—*B. W. Wells*.

120. ZADE. Die Anerkennung von Klee und Gräsern. [Certification of clover and grasses.] Mitteil. Deutsch. Landw. Ges. 37: 384-386 1922.—The statement covers the requirements for certifying fields of clover and grasses for seed production.—A. J. Pieters.

BIBLIOGRAPHY, BIOGRAPHY, AND HISTORY

(See also in this issue Entries 44, 53, 59, 60, 79, 91, 267, 384, 426, 467, 478, 480, 497, 509, 534, 608, 731, 762, 763, 788, 808, 884)

121. ANONYMOUS. A list of one hundred popular books in science. Jour. Washington [D. C.] Acad. Sci. 11: 353-356. 1921.—At the request of Geo. F. Bowerman, Librarian of the Public Library of the District of Columbia, a committee of the Academy has compiled a list of scientific books which can be recommended for popular use. The following are of interest to botanists: Darwin, The Origin of Species; East and Jones, Inbreeding and Outbreeding; Castle, Coulter, Davenport, East, and Tower, Heredity and Eugenics; Morgan, A Critique of the Theory of Evolution; Conklin, Heredity and Environment; Galton, Hereditary Genius; Popenoe and Johnson, Applied Eugenics; Lotsy, Evolution by means of Hybridization; Ganong, The Living Plant; Osterhout, Experiments with Plants; Sorauer, A Popular Treatise on the Physiology of Plants; Lubbock, Flowers, Fruits, and Leaves; Hardy, The Geography of Plants; Darwin, Insectivorous Plants; Townsend, Sand Dunes and Salt Marshes.—Helen M. Gilkey.

122. ANONYMOUS. Current topics and events. Nature 109: 383. 1922.—Rothamsted Station has taken over the Stockyard field, Woburn, held by the Royal Agricultural Society for many years. The Society will continue investigational work on the fields belonging to its members.—O. A. Stevens.

123. ANONYMOUS. Dr. A. B. Rendle. Gard. Chron. 70: 256. *Portrait*. 1921.—A brief biographical sketch is presented.—P. L. Ricker.

124. ANONYMOUS. E. H. Jenkins. Gard. Chron. 70: 266. *Portrait*. 1921.—E. H. Jenkins, author of The Rock Garden, Hardy Flower Book, and many articles in the horticultural journals, died Nov. 9, 1921, in his 66th year. A brief sketch of his work is included.—P. L. Ricker.

125. ANONYMOUS. Edwin Molyneux. Gard. Chron. 70: 266, 268, 281, 282. 1921.—A biographical sketch is given of Edwin Molyneux (1851-Nov. 12, 1921).—P. L. Ricker.

126. ANONYMOUS. Sir Isaac Bayley Balfour. Gard. Chron. 71: 161-162. *Portrait*. 1922.—His retirement as keeper of the Edinburgh Botanical Garden is noted; a brief biographical study is presented.—P. L. Ricker.

127. ANONYMOUS. The British cotton industry research institute. Nature 109: 457-458. 2 fig. 1922.—A detailed description with floor plan is given of the recently opened laboratory of the British Cotton Industry Association at the Shirley Institute, Didsbury, Manchester.—O. A. Stevens.

128. ANONYMOUS. The director of Kew. Gard. Chron. 71: 85. 1922.—A brief sketch is presented of Sir David Prain on the occasion of his retirement from the Kew directorship, now assumed by A. W. Hill.—P. L. Ricker.

129. ANONYMOUS. The origin of the potato. [Rev. of: HEDRICK, U. P., Editor. Sturtevant's notes on edible plants. Rept. New York Agric. Exp. Sta. [Geneva] 1919²: i-vii, 1-686. *Portrait*. 1919 (see Bot. Absts. 8, Entry 862).] Gard. Chron. 71: 37. 1922.

130. ANONYMOUS. Thomas Andrew Knight as a pomologist. *Gard. Chron.* 71: 201. 1922.—This is a brief sketch of Knight's work made on the occasion of the award of the Knightian and Hogg medals.—*P. L. Ricker.*

131. ARBER, E. A. NEWELL. Sketch of the history of paleobotany with special reference to the fossil flora of the British coal measures. *Studies Hist. and Method of Sci.* 2: 472-489. *Pl.* 48-55, 1 fig. 1921.—In the prescientific period Lhuyd (Lhuyd or Luidius) (1660-1709) published a catalog describing plant fossils. Woodward (1665-1728) and James Parsons (1705-1770) advocated the flood theory of the origin of plant fossils, even giving the season of the year in which it occurred. Robert Plot (1640-1696), David Ure, and Emanuel Mendes da Costa (1717-1791) further advanced the science. The first binomials were applied by Henry Steinhauer and published in Philadelphia, Pennsylvania, in 1818. Ernst Friedrich Baron von Schlotheim (1764-1830), William Martin (1767-1810), and James Parkinson (d. 1824) belong to this transitional period. The pioneers of the scientific period were interested primarily in taxonomy. Kaspar Maria Graf von Sternberg (1761-1838), Adolphe Theodore Brongniart (1801-1876), Edmund Turell Artis (1789-1847), John Lindley (1799-1865), and William Hutton (1798-1860) published systematic accounts. William Nicol (?1768-1851) first studied sections of petrifications, publishing in 1831-1835. Henry Thomas Maire Witham (1779-1844) also began publication in this field in 1831. The modern period, beginning about 1870, has been more purely botanical in outlook.—*C. W. Dodge.*

132. BAZELEY, MARGARET LEY. The extent of the English forest in the 13th century. *Trans. Roy. Hist. Soc. London* IV, 4: 140-172. 2 maps. 1921.

133. BROTHERSTON, R. P. Donald Beaton. *Gard. Chron.* 71: 196. 1922.—Brief mention is made of his life, work, and writings.—*P. L. Ricker.*

134. BROTHERSTON, R. P. The Antirrhinum. *Gard. Chron.* 70: 248. 1921.—No date of introduction into cultivation has been found; Turner states it was brought from Italy. A few color variations were known in 1578, and it is figured by Parkinson. By 1824 there had been considerable progress in its development. In 1844 a double-flowered variety appeared. Notes are given on cultivation.—*P. L. Ricker.*

135. BROTHERSTON, R. P. The greenhouse, hothouse, and stove. *Gard. Chron.* 71: 78. 1922.—The article, dealing with the above work of Charles McIntosh (b. 1794), includes a brief biographical sketch and notes on plants cultivated during this early period.—*P. L. Ricker.*

136. BROTHERSTON, R. P. The nettle as a food. *Gard. Chron.* 71: 232. 1922.—Three quotations are given from Scotch verse regarding the nettle, together with data as to its former extensive use as a medicine and for human and stock food.—*P. L. Ricker.*

137. BUNYARD, E. A. An early Vilmorin catalogue. *Gard. Chron.* 71: 78. 1922.—Notes are given on an octavo volume of 130 pages published in 1771. This old catalogue includes a list of 22 varieties of strawberries and some flowers as well as a long list of pears.—*P. L. Ricker.*

138. CHIOVENDA, E. Odoardo Beccari. *Nuovo Gior. Bot. Ital.* 28: 5-35. *Portrait.* 1921.—Odoardo Beccari, born Nov. 19, 1843, was educated at R. Collegio di Lucca and at the University at Pisa. After a brief period of study at Kew he joined Doria on an expedition to Borneo (1865-1868). On his return he founded the *Nuovo Giornale di Botanica Italiana*, in 1870 he spent a year in the orient, and joined the D'Albertis expedition to New Guinea (1871-1876) and other parts of the orient (1877-1878). He succeeded Parlatore as director of the museum and botanical garden at Florence (1878-1897). His life was devoted to the study of tropical plants, especially palms. He died Oct. 25, 1920. His biography is followed by an exposition of his biological theories and a bibliography of 10 pages.—*C. W. Dodge.*

139. CORONADO, J. A. *Resumen de mi bibliographia general sobre el café.* [Résumé of my bibliography of coffee.] *Bol. Camara Agric. Costa Rica* 1: 282-288. 1921.

140. [DUDGEON, WINFIELD.] *Indian Botanical Society Bulletin. No. 2.* 8 p. Allahabad. 1921.—A little publication appearing at irregular intervals, intended to promote the interests of the Society. This number contains a plea to make the encouragement of research the primary aim of the Society; and news notes of interest to members. The 1st issue [see *Bot. Absts.* 8, Entry 846] was not numbered. [See also 2 succeeding entries.]—*Winfield Dudgeon.*

141. [DUDGEON, WINFIELD.] *Indian Botanical Society Bulletin. No. 3.* 10 p. Allahabad. 1922.—A list of members complete to date and the program for the annual meeting at Madras in February, 1922, are given.—*Winfield Dudgeon.*

142. [DUDGEON, WINFIELD.] *Indian Botanical Society Bulletin. No. 4.* 14 p. Allahabad. 1922.—This issue of the bulletin contains a supplementary membership list; a report of the annual meeting at Madras in February, 1922; and plans for carrying on the work of the Society.—*Winfield Dudgeon.*

143. FARSKY, OCT. *Fytopathologická sekce výzkum. ústavu zemědělského v Brně a organisace fytopathologické služby na Moravě, Slezku, Hlučínsku a Valčicku.* [Section for phytopathology in the agricultural experiment station in Brno (Brünn) and organisation of phytopathological work in Moravia, Silesia, Hlučínsko, and Valčicko.] *Ochrana Rostlin* 1: 27, 28, 38-39. 1921.—The agricultural experiment station at Brünn was founded in 1899. A section of phytopathology was established in 1919 but the work did not begin until the winter of 1920. The head of the station is Docent Dr. E. Baudyš. With him are associated 4 scientific investigators (adjuncts), 1 assistant, and 1 laboratory assistant. The work of the section consists of determination and study of diseases, tests of chemicals and apparatus used in control and organization of their production, preparation of calendars and maps of the distribution of diseases, organization for statistical and inspection purposes, and selection of resistant varieties. Interest in phytopathology is stimulated by lectures, field demonstrations, and leaflets.—*E. Baudyš.*

144. FIALON, CHARLES-HENRI. *History of the words "pharmacie" and "apothicaire."* *Amer. Druggist and Pharm. Rec.* 70: 18-19. 1922.—The author traces the words from their Greek origin and shows how they were first used synonymously. "Apothicaire" was finally abandoned, and now only "pharmacist" is given as a title.—*C. M. Sterling.*

145. G[ATES], R. R. [W. B. Bottomley.] *Nature* 109: 524-525. 1922.—W. B. Bottomley was born at Leeds, December 26, 1863, and died March 24, 1922. He was educated at Royal Grammar School, Lancaster, King's College, Cambridge, and at Heidelberg, where he received his Ph. D. degree. A lecturer at St. Mary's Hospital from 1886 to 1891, he was next appointed to the professorship of biology at the Royal Veterinary College, serving also as assistant to Prof. Oliver at University College, London, and as Cambridge University Extension lecturer. From 1893 to 1920 he was professor of botany at King's College, London. His chief interests were with plant nutrition and its relations to agriculture. His most important contribution was the discovery of "auximones," growth-promoting substances which withstand a temperature of 150°C.—*O. A. Stevens.*

146. GUENTHER, FRITZ. *Friedrich Lucas.* *Gartenwelt* 25: 180. 1921.—Friedrich Lucas was born October 30, 1842, in Regensburg, and died August 21, 1921 in Reutlingen. He devoted his life to pomology, writing much on this subject. Until his death he was director of the pomological institute in Reutlingen, Germany.—*J. C. Th. Uphof.*

147. GULICK, ADDISON. *Charles Darwin, the man.* *Sci. Monthly* 15: 132-143. 1922.

148. GUNTHER, R. T. **Early British botanists and their gardens based on unpublished writings of Goodyer, Tradescant and others.** vi + 417 p., 9 pl., 29 fig. University Press: Oxford, 1922. 42 s.—John Goodyer was born at Alton in Hampshire in 1592. For some years he was a steward of Sir Thomas Bilson at West Mapledurham. About 1632 he married and settled at Petersfield, where he died in 1664. He translated Dioscorides and Theophrastus, described many plants, and annotated many of the older herbals. His plant descriptions are printed in full and a careful catalog of his library is given. Many data from the Goodyer papers are given concerning Thomas Penny (1530–1589), a botanist of Oxford and Winchester, (?Walter Bayley 1529–1592), Richard Garth (d. 1597), William (1520?–1600?) and Sir John Salusbury of Lleweni (1567–1612), M. l'Obel (1538–1616), Wm. Mount (1545–1602), Richard Shanne (1561–1627), John Parkinson (1567–1650), Walter Stonehouse (1597–1655), Thomas Johnson (?1600–1644), William How (1619–1656), John Dale (d. 1662), and William Browne (1629–1678). Biographical information of many of their contemporaries appears in footnotes. Garden lists from several of the above as well as from Simon Forman, Lord Salisbury, William Coys Franqueville, John Tradescant the elder, George Gibbes, Edward Morgan, and Robert Morison are given. The work of William Coys on cultivation of yeast and beer making is printed.—The book is well indexed and well illustrated by reproductions from contemporary herbals and by facsimiles of the manuscripts.—*C. W. Dodge.*

149. J[ATUL], P. A. **Abstraktai iš Musū Botanikos.** [Abstracts from our botanists.] *Želmenija* 2: 76–78. 1922.—A brief history of Lithuanian botany to the close of the 19th century is followed by 14 short abstracts of agricultural and botanical articles.—*C. W. Dodge.*

150. JATUL, P. A. **Arnold Arboretum.** *Želmenija* 2: 73–75. 1922.—A brief historical account of this institution is given with a list of the publications issued by it.—*C. W. Dodge.*

151. LIVINGSTONE, R. W., Editor. **The legacy of Greece.** 424 p., 36 fig. Clarendon Press: Oxford, 1921.—This is a collection of historical essays, of which those dealing with biology and medicine are by CHARLES SINGER. On the botanical side, attention is directed to the anonymous work on generation (380 B. C.) and later works by Aristotle, Theophrastus, Crateuas (1st century B. C.) Pliny, and Dioscorides.—*C. W. Dodge.*

152. LYMAN, G. R. **Report of the thirteenth annual meeting of the American Phytopathological Society.** *Phytopathology* 12: 195–204. 1922.

153. McCALLUM, A. W. **Abstracts of Canadian plant pathological literature.** *Quebec Soc. Protection Plants Ann. Rept.* 14: 110–115. 1922.—Abstracts of and references to papers published during 1921 are given together with those missed in the previous lists. Some 97 references are included.—*B. T. Dickson.*

154. MENZIES, DAVID. **Dr. Archibald Menzies.** *Gard. Chron.* 70: 320, 324. Fig. 143–145. *Portrait.* 1921.—A brief biography and account of his travels and plant introductions are presented.—*P. L. Ricker.*

155. OBERLY, E. R. **The contribution of librarians to agricultural history and research.** *Library Jour.* 47: 249–254. 1922.—A brief discussion of the routine work of the reference librarian is followed by an account of the development of library facilities in the U. S. Department of Agriculture. Attention is called to many bibliographies covering a wide range of agricultural subjects.—*C. W. Dodge.*

156. PARKER, W. H. **The national institute of agricultural botany.** *Jour. Ministry Agric. Great Britain* 28: 1072–1084. 2 fig. 1922.

157. RICHARDSON, A. D. **The Arncliffe larches.** *Gard. Chron.* 71: 258–259. 1922.—No authentic record of date of introduction of the larch into England has been found. The larch

is in Gerard's catalogue of 1596 and not found again until mentioned by Parkinson in 1629. The Arniston Memoirs (1887) indicate that those on the estate were planted in 1738. Other early records of England and Scotland are given.—*P. L. Ricker.*

158. RIEFSTAHL, MEYER R. The pictures of plowing and weaving. Asia 20: 1059-1063. 10 fig. 1920; 21: 47-51. 10 fig. 1921.—Notes are given on the editions of a famous Chinese agricultural treatise with reproductions of several illustrations from an 18th (?) century edition.—*C. W. Dodge.*

159. ROBERTS, W. A seedman's broadside. Gard. Chron. 71: 54. Fig. 27. 1922.—The heading is reproduced of a 1769 seed list of Vilmorin & Co., and a brief early history of the firm is given.—*P. L. Ricker.*

160. ROBERTS, W. The Auricula. Gard. Chron. 69: 310. 1921.—One of the earliest accounts of this popular English garden plant is given in John Rea's Flora in 1665. Its full popularity was not reached until the 18th century. The names of many early varieties and a sales list of 1756 quoted from a letter to Dr. Richard Richardson from the younger Bobart. A Treatise on the Culture and Management of the Bear's Ear, or *Auricula ursi*, written by "a Florist of nearly 30 years' experience," and printed at Bath, England, in 1782, enumerated 250 varieties. Some were then sold as high as £ 50. Further historical notes down to 1816 are given. [A few corrections and comments on this article are given by C. HARMAN PAYNE, Gard. Chron. 70: 21. 1921.].—*P. L. Ricker.*

161. ROPER, I. M. The earliest English herbal. Somersetshire Archaeol. and Nat. Hist. Soc. Proc. 67: 65-71. 1922.—A popular paper on the life and work of William Turner (1510-1568), dean of Wells Cathedral, is followed by notes by J. HAMLET which add bibliographical information and call attention to his letters published in Calendar of State Papers, Domestic. Edward VI 7: no. 32; 10: no. 34; 11: no. 14; 13: no. 1, 19. 1856.—*C. W. Dodge.*

162. SAVAGE, S. The discovery of some of Jacques Le Moyne's botanical drawings. Gard. Chron. 71: 44. 1922.—Notes are given on a collection of 59 excellent water color drawings found at the Victoria and Albert museum, South Kensington. Le Moyne accompanied one of the French expeditions to America as an artist and later settled in London, where he died in 1588. He published a book of wood cuts of animals, birds, and plants in London in 1586.—*P. L. Ricker.*

163. SINGER, CHARLES. Greek biology and its relation to the rise of modern biology. Studies Hist. and Method of Sci. 2: 1-101. Pl. 1-25, fig. 1-43. 1921.—Greek science has left its conclusions without a hint of the processes of reasoning which led to them. The work of the rhizotomists, Theophrastus and Nicander, the probable author of the Alexipharmaca and Theriaca, is briefly discussed. More attention is given the work of Crateuas and his tradition in the Julia Anicia MS. The Greek codices of Dioscorides and their tradition is carefully discussed. Two schools of botanical illustration are discerned: the Naturalistic, spreading from southern Italy perhaps along with Beneventan script and influence, and the Romanesque, spreading from northern and eastern France. Improvement begins with the De Vegetabilibus of Albertus Magnus (1206-1280), compiled from Nicolas of Damascus. The manuscripts and early editions of the Herbarius and the Hortus Sanitatis are described. The growth of the knowledge of classification, of generation and development, of form and structure, and of habit and distribution is further discussed with quotations from many sources from Theophrastus to the 16th century. The article is well illustrated by reproductions in color from illuminated manuscripts dating from the 5th to the 15th century.—*C. W. Dodge.*

164. SINGER, CHARLES. Steps leading to the first optical apparatus. Studies Hist. and Method of Sci. 2: 385-413, 533-534. Fig. 1-11. 1921.

165. STRAŇÁK, FR. *Organisace služby rostlino-lékařské v republice Československé.* [Organization of phytopathological work in the republic of Czecko-Slovakia.] *Ochrana Rostlin* 1: 14-15. 1921.—Agricultural institutions are united into "Svaz pro zemědělské a zemědělsko-prumyslové výzkumnictví" (a union for the investigation of agriculture and agricultural industries). In the union there is a commission for phytopathology which is responsible for the organization of phytopathological work in the whole republic. The activity consists of securing information and statistics, publicity, control, and research. Results are collected by central stations at Praha (Prague), Brno (Brünn), Bratislava (Pressburg), and Košice. Besides these stations there are substations in Roudnice, Tabor, and Libverda. Estimates for statistics are made by collaborators named by the minister of agriculture. This work is honorary. Extension work is carried on through lectures, field demonstrations, exhibitions, and publications.—*E. Baudyš.*

166. TAUBENHAUS, J. J. Report of the fourth annual meeting of the Southern Division of the American Phytopathological Society, at Atlanta, Georgia, Feb. 20-22, in connection with the general meeting of the Association of Southern Agricultural Workers. *Phytopathology* 12: 249. 1922.

167. THOMPSON, J. ARTHUR. *Science and the farmer.* *Jour. Ministry Agric. Great Britain* 29: 217-223. 1922.

168. TRELEASE, SAM F., and EMMA S. YULE. *The preparation of theses and other manuscripts.* 20 p. College Coöperative Co., Inc.: Los Baños, Laguna, Philippine Islands, 1919.

169. VIELWERTH, VL. *Organisácia rostlinolekárskej služby na Slovensku.* [Organization of phytopathological work in Slovakia.] *Ochrana Rostlin* 1: 9-10. 1921.—Slovakia is divided into eastern and western districts because of difference in agriculture. The work in the western part is carried on by Státní ústav pro zdravotnú ochranu rostlin (state institute for the control of plant diseases) located in Bratislava (Pressburg), and in the eastern part of the state agricultural experiment station in Košice, which has a department for plant pathology.—*E. [The institution for higher horticultural education.] Gartenwelt 26: 382-384. 1922.—The writer compares lower, middle, and higher education in horticulture, especially with reference to German conditions. A critical, detailed outline is given of sciences which are adaptable to higher education in horticulture.—J. C. Th. Uphof.

177. LLOYD, F. E., and G. W. SCARTH. An introductory course in general physiology. 8vo., 16 p. Privately printed: Montreal, 1921.—This work includes outlines of laboratory exercises based on extensive experience in teaching, especially the teaching of medical students and is intended as an introduction to modern physiological methods of study in the field covered. Materials and experiments are briefly indicated, the purpose being to put problems before the student. The work assumes the completion of a course in general biology. The materials are chiefly, but not exclusively, botanical. Synopses of the different parts follow: (1) review of biological material (general morphology of living cell), (2) surface tension, (3) colloidal state, (4) hydrogen-ion concentration, (5) diffusion and osmosis, (6) digestion, role of enzymes. Each synopsis is divided into 2 parts; (a) physical phenomena, (b) behaviors in protoplasm more or less susceptible of explanation in the light of (a).—F. E. Lloyd.

CYTOLOGY

G. M. SMITH, *Editor*

(See also in this issue Entries 406, 420, 777)

181. BALLY, WALTHER. Einige Bemerkungen zu den amitotischen Kernteilungen der Chytridineen. [Observations on the amitotic nuclear division of the Chytridineae.] Ber. Deutsch. Bot. Ges. 37: 103-107. Fig. 1. 1919.—This paper is a defense of the author's previously published statements of the occurrence of amitotic division in the primary nucleus of *Synchytrium Taraxaci*. On the basis of a re-examination of his preparations, and a comparison of *Synchytrium* species with *Chrysophlyctis endobiotica*, the author reaffirms the occurrence of the amitotic divisions and denies Rytz's assertions that they are artifacts brought about by the fixing solution.—R. M. Holman.

182. CLELAND, RALPH E. The reduction divisions in the pollen mother cells of *Oenothera franciscana*. Amer. Jour. Bot. 9: 391-413. 3 pl. 1922.—The stages from the resting condition preceding the heterotypic prophase up to the formation of spores are described in detail. Because of the absence of parallelism at all stages and from certain other facts a telosynaptic rather than a parasynaptic interpretation at the spireme is favored. The chromosomes of the last archesporial mitosis are apparently arranged according to a definite plan, so that they come to occupy the same relative position in the subsequent prophase stages. The nucleole seems to store material of some sort, probably chromatin, and is formed anew in each nucleus. This species is very stable genetically and its reduction processes are also very

regular and typical, thus resembling *O. grandiflora* but differing markedly from the less stable species of the genus.—*E. W. Sinnott.*

183. CONN, H. J. American biological stains compared with those of Grüber. *Science* 55: 284-285. 1922.—Tests of stains have proved American products to be equal to Grüber stains. Both are found to vary widely.—*C. J. Lyon.*

184. CONN, H. J., and others. Preliminary report on American biological stains. *Science* 56: 156-160. 1922.—The committee, organized under the auspices of the National Research Council, reports on the utility of American dyes for bacteriology. They recommend the medicinal quality of methylene blue manufactured by Coleman & Bell Co., National Aniline and Chemical Co., or Providence Chemical Co. For staining bacteria and for use in the Endo medium, satisfactory samples of basic fuchsin, as good as Grüber's dye, were obtained from several companies. Gentian violet includes a variety of dyes and stains. For Gram stain, crystal violet (hexamethyl-pararosanalin) is recommended in place of gentian violet; also for other work unless it be known that crystal violet will not work. Crystal violet can be obtained pure from nearly all dealers. The c. p. haematoxylin prepared by McAndrews & Forbes is generally rebottled by other concerns without change and seems to be the only c. p. product on the market. For eosin, it is unsettled what brands are best. For orange G, the products of several prominent companies appear to be satisfactory; all seem to be more concentrated than the Grüber product. For pyronin, few samples have been tested, but that of Providence Chemical Co. proved satisfactory.—*C. J. Lyon.*

185. DANGEARD, P. A. Sur la nature du sphérome dans la cellule végétale. [On the nature of the sphérome in the plant cell.] *Compt. Rend. Acad. Sci. Paris* 173: 1038-1041. 1921.—Dangeard objects to Guilliermond's use of the term sphérome for the ordinary granules which develop during the metabolism of the cell. These granules do not stain when subjected to mitochondrial methods of microtechnique.—*C. H. Farr.*

186. DANGEARD, PIERRE. Sur l'origine des vacuoles aux dépens de l'aleurone pendant la germination des Graminées. [On the origin of vacuoles from aleurone during the germination of cereals.] *Compt. Rend. Acad. Sci. Paris* 174: 319-321. 12 fig. 1922.—The aleurone grains or proteoplastids originate from primordia comparable to those of the chloroplasts. The structures giving rise to the aleurone grains in corn, wheat, rice, and oats are figured and described. Aleurone grains are not special plastids, but represent elements of the vacuome, as in *Pinus* and *Ricinus*. Aleurone grains give rise to vacuoles during germination.—*C. H. Farr.*

187. DEVISÉ, RENÉ. La figure achromatique et la plaque cellulaire dans les microsporocytes du "*Larix europaea*." [The achromatic figure and the cell plate in the microsporocytes of *Larix europaea*.] *La Cellule* 32: 247-309. Pl. 4. 1922.—The use of microtechnique methods in the study of the achromatic figure shows that it is entirely of nuclear origin.—During the winter rest period the nucleus of the microsporocyte is in an advanced prophase stage, and the cytoplasm is homogeneous and contains many chondriocents; the cytoplasmic reticulum observed after Flemming's and other fluids is an artifact, and the droplets associated with it are largely altered chondriosomes. In early spring the chondriocents move endwise toward the nucleus and lay themselves parallel to its membrane, forming a dense "perinuclear chondriosomal mantle." Improper fixation of these structures gives the "radial stage" and "felted stage" of other authors. The chondriosomal mantle remains intact throughout mitosis, its inner boundary marking the limit of the nuclear area. As the nuclear membrane disappears the chromosomes become grouped at the center of the nucleus, the peripheral portion of which is then occupied by a substance representing karyolymph which has been rendered denser, probably through the influence of the cytoplasmic fluid. It is possible that the nucleolar material also plays a rôle here. The spindle arises wholly from this peripheral intranuclear substance, the cytoplasm contributing no formed element. The spindle fibers,

which are no more numerous than the chromosomes, do not invade the nucleus from without; they appear first at the surface of the chromosomes and develop centrifugally until the completed spindle extends across the nuclear region with its poles at the chondriosomal mantle and surrounded on its flanks by the intranuclear substance. The figure is bipolar from the start. Multipolar spindles are artifacts arising through alterations of the chondriosomes and intranuclear substance, as are also the many "mantle fibers" said to surround the spindle proper,—the greater the alteration of the chondriosomes in fixation the more numerous the fibers. The fibers are not such in the strict sense, but are rather lamellae bounding elongated alveolae.—At telophase the terminal portions of the spindle and the remaining intranuclear substance become 2 masses of hyaline fluid in which the chromosomes lie and around which the chondriocents are grouped. The daughter nuclei are reconstituted in these hyaline areas—in substance which is continuous with that of the mother nucleus. The remains of the spindle disappear between the daughter nuclei, no wall forming after the 1st maturation mitosis. The chondriosomes form mantles around the nuclei. The origin and behavior of the achromatic figure in the 2nd mitosis is essentially the same as in the 1st.—Cytokinesis after the 2nd mitosis begins with the formation of a cell plate, which first appears as a delicate layer in the homogeneous material between the spindle fibers. It is not formed by the union of swellings on the fibers; the fibers appear to be wholly passive and show no swellings in well fixed preparations. The cell membrane forms by the deposition of material in the cell plate.—*L. W. Sharp.*

188. DRAGOIU, J. Influence de la pression osmotique sur la division cellulaire. [The influence of osmotic pressure on cell division.] *Compt. Rend. Acad. Sci. Paris* 174: 199–202. 1922.—This supplementary report on the effect of hypertonic solutions of 30–50 atmospheres pressure on the mitosis of sea-urchin eggs shows that in some cases the nucleus regains its ability to divide after being returned to normal sea water. In most concentrations, however, there is no recovery after return to sea water.—*C. H. Farr.*

189. FARR, CLIFFORD H. The meiotic cytokinesis of *Nelumbo*. *Amer. Jour. Bot.* 9: 296–306. 1 pl., 1 fig. 1922.—In cytokinesis of pollen mother-cells of *Nelumbo lutea* the walls are unequally thickened on various sides of the same cell. There is a succession of division stages from one part of the anther to another though not always from one end to the other. From the comparative abundance of the stages, it is evident that karyokinesis proceeds much more rapidly than does cytokinesis. Eight seems to be the haploid chromosome number. After the heterotypic division, an incomplete and transitory cell plate is formed which disappears in interkinesis; no plate is formed after the homoeotypic division. Following the tetranucleate stage, quadripartition of the cell occurs by furrowing, the furrows being very slender. The spindle fibers now disappear, the walls become thicker, and the microspores round up.—*E. W. Sinnott.*

190. GEORGEVITCH, PIERRE. L'origine du centrosome et la formation du fuseau chez *Stypocaulon scoparium* (L.) Kutz. [The origin of the centrosomes and the formation of the spindle in *Stypocaulon scoparium*.] *Compt. Rend. Acad. Sci. Paris* 174: 695–696. 1922.—It is reported that both the centrosome and the spindle arise on the interior of the nucleus. No figures are given.—*C. H. Farr.*

191. G[OLDSCHMIDT], R. [Rev. of: ABDERHALDEN, EMIL. *Handbuch der Biologischen Arbeitsmethoden*. (Handbook of biological technique.) Urban and Schwarzenberg: Vienna, 1920.] *Arch. Zellf.* 16: 285. 1922.

192. GUILLIERMOND, A., et G. MANGENOT. Sur la signification de l'appareil réticulaire de Golgi. [On the significance of the reticular apparatus of Golgi.] *Compt. Rend. Acad. Sci. Paris* 174: 692–694. 1922.—An attempt is made to harmonize the reticulum of Golgi with the canalicules of Holmgren as a modification of the vacuolar system. Descriptions and figures are given of these structures in the meristem of rice roots.—*C. H. Farr.*

193. KELLER, R. Die elektrische Charakteristik der Farbstoffkolloide. [The electrical properties of colloidal dyestuffs.] *Kolloid Zeitschr.* 26: 173-178. 1920.—Solutions of almost all dyestuffs, especially those of animal origin, consist of 2 phases: a colloid phase that obeys the laws of cataphoresis of neutral colloids, and a molecularly dispersed phase with a colored cation. Besides a discussion of the theoretical physical chemistry of these dyes and its experimental basis the author includes some observations on their behavior in plant cells. Most of the simple dyes are anodic in the living plant cell although osmic acid stains fats at the negative pole and Sudan III in alcohol wanders to the cathode. A rule of vital staining is that the dye inside the cell behaves as if it were composed only of its colloidal phase, perhaps due to the adsorption of ions on invisible cell colloids, the migration tendencies of which it shares. The gentian violet-safranin-orange mixture is violet at the anode, yellow-red at the cathode, and stains chromatin violet and cytoplasm yellow-red.—H. E. Pulling.

194. McFARLAND, F. M. Some simplifications of microscopical technique. *Science* 56: 43-44. 1922.—Acetone is recommended as a substitute for alcohol in hydration and dehydration of mounted sections in passing to and from the stains. Absolute acetone is used in 1 bottle and C. P. acetone in 2 other bottles.—In staining ribbons of sections without removal of paraffine, they are floated upon the surfaces of the stains and distilled water, floated into place upon the surface of an albumenized slide, dried, cleared, and mounted. Sections of the same tissues may thus be stained by different methods and mounted side by side for comparison. The removal of the paraffine is necessary only in case a very narrow diaphragm opening is used.—C. J. Lyon.

195. POLICARD, A., et G. MANGENOT. Action de la température sur le chondriome cellulaire. Un critérium physique des formations mitochondriales. [The effect of temperature on the chondriosomes of cells. A physical criterion for the formation of mitochondria.] *Compt. Rend. Acad. Sci. Paris* 174: 645-647. 1922.—A study is reported of living cells of an alga, *Saprolegnia*, the epidermis of young leaves of *Iris*, and the epidermis of petals of tulip. Between 48 and 50°C. rapid alteration of mitochondria occurs; this alteration is in the nature of a vacuolization. The temperature at which the mitochondria completely disappear has not been definitely determined.—C. H. Farr.

196. RANDOLPH, L. F. Cytology of chlorophyll types of maize. *Bot. Gaz.* 73: 337-374. *Pl.* 11-16. 1922.—This study of correlation of cell structure with the known genetic behavior of maize involved observations on living and fixed and stained cells of 4 chlorophyll types of maize, namely, "normal green," "Mendelian white," "Mendelian virescent," and "maternal inheritance strain." All contain the same initial cell structure,—bodies, "proplastids," from which chloroplasts develop later. Proplastids are present in every type and have the same size and general appearance in each case. They are rarely more than 1 μ in diameter. Transitional stages in the development of proplastids into chloroplasts are described for the "normal green" type. The green color is not present in the plastids before they are approximately half the size of mature functional plastids. The other chlorophyll types studied are due to the failure of the proplastids to develop into plastids of normal size or color or both. In the "Mendelian white" the proplastids of green plants are like those of the "normal green," while in the white plants the proplastids neither develop rapidly nor ever reach the size of normal chloroplasts. The extreme tip of the albino seedling leaf, however, has a limited region of cells containing green chloroplasts. In "Mendelian virescent," the formation of chloroplasts with their pigment seems to be merely delayed, but when once started continues until the whole plant becomes green. In "Maternal inheritance strain," the green plants are like those of the "normal green" in cytological details. The yellowish green plants show the series of stages in development of chloroplasts, with exception of maximum size, depth of color, and number per cell. The striped plants show to the naked eye a sharp line between green and yellow green; microscopic examination shows a region of transition, 1 to several cells in width, where the plastids of many intermediate sizes and depths of color are visible, even in a single cell.—Green and colorless plastids in the same or in different plants of chlorophyll types are

regarded as the end members of a continuous series which comprises also all intermediate stages in development. The cells of all chlorophyll types contain only 1 kind of primordium from which plastids arise. Differences appearing later are explained as being dependent upon functional rather than structural bases. The mode of origin of the proplastids could not be determined and the question as to whether they are permanent cell organs or may arise *denovo* is still unsettled. Proplastids have a distinct individuality after they are developed into chloroplasts. The relation of proplastids to chondriosomes and like structures is discussed. In maize strains in which the inherited characters are transmitted according to Mendelian rules, the behavior of the proplastids is thought to be at least in part under control of the nuclear mechanism. In strains in which the inheritance is non-Mendelian, no explanation is given.—*Wanda Weniger*.

197. SCHÜRHOFF, P. N. Die Teilung des vegetativen Pollenkerns bei *Eichornia crassipes*. [The division of the vegetative pollen nucleus in *Eichornia crassipes*.] Ber. Deutsch. Bot. Ges. 40: 60–63. Fig. 1. 1922.—Pollen grains almost always degenerate in the binucleate condition. Some, however, show a typical mitosis of the vegetative nucleus. Inasmuch as Smith found that the chromosomes never showed a V-formed figure in the nuclear division of the embryo-sac mother cell, Schürhoff concludes that no reduction division takes place in pollen mother cells and that the plant is oovogamous.—*R. M. Holman*.

198. SCHWARZE, CARL A. The method of cleavage in the sporangia of certain fungi. Mycologia 14: 143–172. Pl. 15–16, fig. A–F. 1922.—Cytological study of *Olpidiopsis Saprolegniae*, *Saprolegnia torulosa*, *Achlya*, *Sporodinia grandis*, *Mucor racemosus*, *M. mucedo*, *Circinella minor*, *Rhizopus nigricans*, and *Pilobolus crystallinus* shows that "cell-division in the sporangia of algae and fungi is essentially a process of furrowing either from the periphery of the sporangia or from the vacuoles in the interior of the spore plasm." Spore formation in certain fungi, (*Achlya* and *Saprolegnia*) "involves . . . a marked series of contraction and expansion phases" comparable to the oosphere formation in *Vaucheria* described by other investigators. "The process of spore formation may be much abbreviated, as in *Sporodinia grandis*, . . . or it may be protracted, as in *Pilobolus crystallinus*, . . . by the interpolation of an embryonic stage," the protospores. Columella formation is not initiated by a plane cross-wall but by a "dome-shaped mass of vacuoles at the inner boundary of the spore plasm."—*H. R. Rosen*.

199. SEARS, PAUL BIGELOW. Variations in cytology and gross morphology of *Taraxacum*. I. Cytology of *Taraxacum laevigatum*. Bot. Gaz. 73: 308–325. Pl. 9–10. 1922.—The mode of synaptic pairing and cytological variation in *Taraxacum laevigatum* are discussed. The earliest stages of maturation are marked by the presence of 13 paired prochromosomes. On entering synizesis the thread shows a partly paired, partly vacuolate—split—appearance; on emerging from synizesis it is distributed through the nucleus and a non-simultaneous splitting occurs. The formation of 26 univalent chromosomes occurs by lateral refusion of the 2 previously split halves.—After segmentation, diakinesis in *T. laevigatum* may develop further in any 1 of 4 ways, instead of in a uniform sequence as described for other parthenogenetic species of *Taraxacum*. In 1 sequence pairing is end to end following diakinesis and is prompt and complete, a heterotypic metaphase with 13 bivalents resulting. This almost typical reduction division was observed in pollen, but in the embryo sac it has been traced only through the compact orientation stage. Hundreds of embryo sacs failed to disclose tetrad formation, and it is not known whether true reduction occurs. A 2nd sequence, for which the name "ameiosis" is proposed, results in reproduction in that it insures preservation of constant chromosome equipment in the absence of fertilization. The nuclear membrane disappears before synapsis, synaptic pairing is end to end but takes place very slowly. The pairs, 13 in number, come to metaphase with components still end to end and transversely oriented. A quantitative division is brought about. This sequence occurs in pollen resulting in diads which as a rule do not undergo further growth. In the embryo sac a diad results in which the apical cell disintegrates, the basal cell developing into an 8-nucleate embryo sac by vegetative mitoses. The

3rd sequence found seems to bridge the gap between the 1st and 2nd. Pairing of univalents is variable, and premature elongation of the nucleus and defective orientation occur. This sequence is responsible for pollen abnormalities, the chromosomes never reaching the metaphase position and being reorganized into nuclei before those at the center reach the poles. A 4th sequence of amitosis is also responsible for pollen abnormalities. The nucleus elongates prematurely and the split thread persists after segmentation, giving 26 X- and Y-shaped chromosomes without a spindle.—The 4 sequences following segmentation give a new aspect to the previous hypotheses of maturation in parthenogenetic species of *Taraxacum*. The variations are traced to an increasing degree of inhibition of sex by chromosome individuality and polarity.—*Wanda Weniger*.

200. SÜSSENGUTH, K. Bemerkungen zur meiotischen und somatischen Kernteilung bei einigen Monokotylen. [Observations on meiotic and somatic nuclear division in monocotyledons.] *Flora* 114: 313-328. *Fig. 21*. 1921.—In the microsporocyte of *Rhoeo discolor* a continuous double spireme segments into 12 (diploid) split chromosomes, each of which resembles a tetrad because of a transverse constriction. In the heterotypic anaphase 6 of these bodies pass to each pole, and in the homoeotypic mitosis each divides along the plane of the split. Similar appearances are seen in *Thalia dealbata* and *Chamaedorea Karwinskiana*. The behavior of prochromosomes, the frequent pairing of chromosomes in somatic cells, and phenomena in apogamous forms are cited to support the view that somatic and heterotypic mitoses are essentially different in their later stages only. The double spireme of the prophase of both has the same diploid number of split chromosomes placed end-to-end. In somatic mitosis the longitudinal halves of each chromosome separate, so that each telophase nucleus contains 1 portion of every original chromosome. In heterotypic mitosis the halves do not separate, each telophase nucleus containing both portions of $\frac{1}{2}$ the original chromosomes. In both cases the telophase nucleus has the diploid number of daughter chromosomes. Numerical reduction occurs in the homoeotypic division, when the longitudinal halves (daughter chromosomes) finally separate.—*L. W. Sharp*.

201. SWEZY, OLIVE. Mitosis in the encysted stages of *Endamoeba coli* (Loesch). *Univ. California Publ. Zool.* 20: 313-332. *Pl. 29-31*. 1922.—In the encysted *Endamoeba coli* cells, 3 and sometimes 4 successive mitotic divisions occur, resulting in 8 or more nuclei. After fixation the cytoplasm contains much glycogen in the form of 1 or more large masses and a number of slender chromatoid bodies; both represent food reserves used up during the mitoses.—The nucleus has an excentric karyosome and a number of scattered chromatin granules on the linin reticulum and nuclear membrane. The chromosomes are probably 6 in number and split before the spindle is formed. Intranuclear polar masses or centrosomes are formed by division of a part of the karyosome; they remain connected by an intradesmose, and between them the spindle is formed. After the daughter chromosomes separate irregularly the elongated nucleus constricts between the telophase groups and divides into daughter nuclei; the nuclear membrane persists throughout the entire process. There is probably a complete nuclear reconstruction before the next mitosis, the polar mass probably becoming the karyosome, and the chromatin becoming distributed on the linin reticulum and nuclear membrane. The division of the protoplasmic body has not been observed.—*L. W. Sharp*.

202. TERBY, JEANNE. La constance du nombre des chromosomes et de leurs dimensions dans le *Butomus umbellatus*. [The constancy of the number and dimensions of the chromosomes in *Butomus umbellatus*.] *La Cellule* 32: 197-225. *Pl. 2*. 1922.—The chromosomes in the somatic cells are 40 in number and fall into 6 size groups, as follows: group I, 6 chromosomes, 275-325 μ in length; group II, 4 chromosomes, about 200 μ ; group III, 2 chromosomes, 150 μ ; group IV, chromosomes, 100-125 μ ; group V, 20 chromosomes, 75-100 μ ; group VI, 4 chromosomes, about 50 μ . The constancy of such a high number of chromosomes affords further support to the individuality theory, while the constancy of the characteristic dimensions is indicative of qualitative differences among the chromosomes.—*L. W. Sharp*.

GENERAL, FACTORS, MEASUREMENTS

203. ANONYMOUS. [Climatic maps of Maryland and Delaware.] 1921.—The Maryland State Weather Service in cooperation with the U. S. Weather Bureau, the Johns Hopkins University, and the University of Maryland has published 3 colored maps (each 81.5 × 47 cm.) of Maryland and Delaware. The "Blue" map indicates average annual precipitation, the "Red" map average annual temperature, and the "Green" the growing season or "the average number of days intervening between the date of the last freezing temperature in the spring and the date of first freezing temperature in the fall." For the entire state of Maryland the average annual precipitation is approximately 42 inches with an average annual maximum of 52 and minimum of 34 inches. The average annual temperature is 54°F. with an average annual maximum of 58 and minimum of 46. The average growing season is 185 days with 120 and 230 days as extremes.—*Earl S. Johnston.*

204. ANONYMOUS. Important peat deposit near La Paz (Bolivia). *Jour. Amer. Peat Soc.* 14: 28. 1921.

205. ADAMS, CHARLES C., G. P. BURNS, T. L. HANKINSON, BARRINGTON MOORE, and NORMAN TAYLOR. Plants and animals of Mount Marcy, New York, Part I. *Ecology* 1: 71-94. 1920.—In this account of a cooperative study of the timber-line vegetation and the accompanying animal life on Mount Marcy, New York, a general statement of the topographic and geologic relations of the Adirondacks, the climatic conditions of Mount Marcy, and the general aspects of the plant and animal life of the region, is followed by a more detailed account of the instrumental data obtained at 4 stations located at critical points in the vegetative covering of the mountain. The 4 stations chosen were: (a) lower limit of fir forest at 4,250 feet; (b) bog at Tear Lake, at 4,320 feet; (c) dwarf fir forest at 4,890 feet, in the tree crowns and on the ground; and (d) alpine zone above timber line at 4,920 feet. The data concern principally the evaporation, solar radiation, temperature of air, temperature of soil, and analyses of soils at each of these stations.—*Charles A. Shull.*

206. BHIDE, R. K. Drought resisting plants in the Deccan. *Jour. Indian Bot.* 2: 27-43. 1 pl. 1921.—Unusually severe drought in 1918-19 gave opportunity to study drought resistance in many trees, shrubs, and herbaceous perennials. Available moisture in the soil about the roots (determined by drying the soil to constant weight over a sand bath at 45-50°C.) ranged from 0.8 to 3.5 per cent, depending on the character of the soil. As a result of the severe drought most of the herbaceous plants showed decrease in the length and number of branches, decrease in size, and increase in hairiness of leaves, and, apparently, decrease in number of rootlets. Strong storage tap roots are characteristic of these plants.—*Winfield Dudgeon.*

207. COCKERELL, T. D. A. Natural history of Porto Santo. *Nature* 107: 10-11. 1921.—This brief description (chiefly zoological) concerns an island of the Madeira group.—*O. A. Stevens.*

208. DUFRÉNOY, JEAN. Influence de la température des eaux thermales de Luchon sur leur flore. [The influence of temperature of the water on the flora of Luchon.] *Compt.*

Rend. Acad. Sci. Paris 172: 612-614. Fig. 10-14. 1921.—A thermic classification of the waters of Luchon, which are high in sulphur and assimilable iron, corresponds closely to the biological classification according to the mode of symbiosis of the reducing bacteria with the iron and sulphur-oxidizing bacteria. The temperature determines the aspect of the flora.—Filamentous iron bacteria prefer cool and tepid waters; the globular forms (*Siderocapsa*) are ubiquitous and tolerate 43°C. The sulphur-producing types (*Beggiatoa*) live in cool water. *Thiothrix* tolerates 50°C. Only those Thiobacteria of very small diameter endure very hot waters. The formation of sulphur is especially intense between 40 and 50°C., although it is always active.—E. T. Foëx.

209. HELDT, H. Croisière de la Perche en Méditerranée. Détail des opérations. [Cruise of the "Perche" in the Mediterranean. Particulars of the operations.] Bull. Inst. Oceanograph. Monaco 389. 15 p. 1921.—Water conditions are given where fish and plankton were collected.—T. C. Frye.

210. LIVINGSTON, BURTON E., and FORREST SHREVE. The distribution of vegetation in the United States, as related to climatic conditions. Carnegie Inst. Washington Publ. 284. xvi + 590 p., 73 pl. (2 colored), 74 fig. 1921.—This book presents studies that occupied the authors for over 10 years, the results being mainly of a quantitative kind. These studies are based on the principle that the control of plant distribution is largely physiological, that all ecological observations must ultimately be expressed in terms of the physiological processes of the individual plants dealt with. The publication constitutes an attempt to correlate the distribution of the vegetation of the areas studied with the distribution of some of the climatic features that seem most important to plants.—Part I is on the distribution of the vegetation, and is illustrated by 33 charts. The 1st of these is a rather detailed map of the vegetation areas of the U. S. A. The areas considered are: (1) California microphyll desert, (2) Great Basin microphyll desert, (3) Texas semi-desert, (4) Arizona succulent desert, (5) Texas succulent desert, (6) Pacific semi-desert, (7) desert-grassland transition, (8) grassland, (9) grassland-deciduous-forest transition, (10) deciduous forest, (11) southeastern evergreen-deciduous transition forest, (12) southeastern mesophytic evergreen forest, (13) northeastern evergreen-deciduous transition forest, (14) northern mesophytic evergreen forest, (15) western xerophytic evergreen forest, (16) northwestern hygrophytic evergreen forest, (17) alpine summits, and (18) swamps and marshes. Plate 1 is followed by a generalized vegetation chart which depicts the vegetation as 9 areas: desert, semi-desert, grassland, grassland-deciduous-forest transition, deciduous forest, northwestern hygrophytic evergreen forest, southeastern mesophytic evergreen forest, northern mesophytic evergreen forest (west), northern mesophytic evergreen forest (east). This chart forms the base for many of the later charts. Plates 2-33 show vegetation features. Three of these present the various degrees of density in the distribution of 3 selected species. Seventy selected species are charted on 23 plates as to the geographical limits of their distributional areas.—Part II deals with the environmental conditions for plant life in the U. S. A. The physiology of conditional control is first somewhat thoroughly presented, after which the main environmental conditions of the U. S. A. are shown by 39 climatic charts, with full tables of data and discussions. Plate 34 deals with the length of the average frostless season. Plates 35 to 45 are charts showing as many different indices of temperature conditions, many of which are derived by new methods. Plates 46-52 deal with precipitation indices, many of which are new. Plates 53-56 present evaporation indices, including those obtained by porous-cup atmometry in 1908. Precipitation-evaporation ratios are presented by the charts of plates 57-62. Two charts (63 and 64) deal with aqueous-vapor pressure and 3 (65-67) with relative air humidity. One chart (68) presents indices of wind velocity and 1 (69) deals with sunshine duration. Moisture-temperature indices are presented by 3 charts (70-72). Plate 73 is a reproduction in colors of Merriam's chart of life zones. Special attention is given to the several temperature and moisture provinces of the U. S. A. and to the charting of the area of this country by means of those 2 criteria.—Part III presents the results of an elaborate attempt to correlate the 32 vegetational charts with the 39 climatic ones. A new kind of quantitative climatic description for each vegetational area is

obtained, these being shown by 130 tables and 53 diagrams. This part of the book represents a very extensive study of the relations holding between the sizes, shapes, and geographic locations of the several vegetational areas and the climatic index values that are shown as belonging to these areas.—*B. E. Livingston.*

211. MOORE, BARRINGTON. The relative length of day and night. *Ecology* 1: 234-237. 1920.—A general review is made of the subject, mentioning a number of contributions to our knowledge of the influence of light upon plant growth and reproduction. Special attention is given to Garner and Allard's work [see *Bot. Absts.* 5, Entry 22], the author pointing out the bearing of their experiments on problems of plant distribution. Suggestions are made for a study of the flowering period of plants in different latitudes, and the author thinks that possibly the same influence has a direct bearing on periodic hibernation and migration of animals.—*Charles A. Shull.*

212. OYE, P. VAN. Influence des facteurs climatiques sur la répartition des épiphytes à la surface des troncs d'arbres à Java. [Influence of climatic factors on the occurrence of epiphytes on the surface of tree-trunks in Java.] *Rev. Gén. Bot.* 33: 161-176. 1921.—The occurrence of epiphytes on tree trunks in the Dutch Indies depends chiefly on light and humidity. For *Trentepohlia* the influence of light is preponderating. The lichens develop where the atmosphere is dry and light. Mosses are found in situations having rather humid atmospheres. *Drymoglossum* was influenced by both light and humidity, usually favoring the south side of the trees. The observations were made at Tasikmalaya, at an altitude of 350-400 m.—*J. C. Gilman.*

213. PEARSON, G. A. Factors controlling the distribution of forest types. Part I. *Ecology* 1: 139-159. 8 fig. 1920.—An account of the factors controlling forest distribution in the San Francisco Mountains of Arizona is given. Five forest associations are considered, the pinon-juniper, yellow pine, Douglas fir, Engelmann spruce, and alpine. The climatic factors discussed are temperature, precipitation, wind, and evaporation. Detailed analyses of the data are presented. The origin and general character of the soil, the available soil moisture, and soil temperatures are the edaphic factors presented.—*Charles A. Shull.*

214. RUSSELL, E. J., and E. H. RICHARDS. The amount and composition of rain falling at Rothamsted. [Based on analyses made by the late Norman H. J. Miller.] *Jour. Agric. Sci.* 9: 309-337. 1919.—Analyses of rainwater for the 10 years 1905 to 1915 are given, with discussion of the data from 1870.—*D. Reddick.*

215. SCHMID, GÜNTHER. *Centaurium pulchellum* (Druce) Sw. auf Bittersalzboden. [Centaurium pulchellum in soil rich in magnesium sulphate.] *Ber. Deutsch. Bot. Ges.* 38: 58-68. Fig. 1. 1920.—In the vicinity of Jena below the "Sophienhöhe," gypsum and dolomite are closely associated and as a result magnesium sulphate has been formed. On shallow soil formed by the weathering of rock and containing at least 10 per cent magnesium sulphate in addition to a large quantity of calcium sulphate, the author found a group of somewhat more than 100 dwarf plants of *Centaurium pulchellum* (*Erythraea pulchella* Fries), each with a single flower. The plant, which corresponds closely to the variety *palustre* Schinz et The llung, has not previously been reported from Thuringia. The author discusses the causes of the rarity in central Europe of areas where the soil is rich in magnesium sulphate. The dimensions of the dwarf plants and their different organs are presented in a table together with corresponding measurements of normal plants found in the same vicinity on soil containing much less of the salt. The normally pentamerous flowers are, in the dwarf plants, for the most part tetramerous; this tendency toward tetramery is more marked in the smaller plants. The small size, absence of branching, production of but 1 flower on a plant, and tendency to tetramery in the dwarf plants are interpreted as expressions of unfavorable conditions for nutrition.—*R. M. Holman.*

216. SEARS, PAUL B. **Vegetation mapping.** *Science* 53: 325-327. 1921.—Two suggestions are here presented. The 1st is a statement of the practical use of a set of symbols to represent genera of plants as transcribed from surveyors' field notes to maps; a workable map results. One concrete instance of its use in the Erie Basin of Ohio is described in some detail.—The 2nd suggestion has to do with the use of the airplane in sketching the various areas of vegetation types. From the airplane these types are distinct and can be comfortably sketched to form the basis of field studies and to serve as a check on final conclusions. The methods were tested in flights made at Arcadia, Florida.—*C. J. Lyon.*

217. SHULL, CHARLES A. **Evaporation in Kansas.** *Trans. Kansas Acad. Sci.* 29: 118-130. *Pl. 1-15.* 1920.—A comparison is made of the evaporation and rainfall at Lawrence and Tribune, Kansas, during parts of 1916 and 1917.—*F. C. Gates.*

218. THOULET, J. **Circulation océanique. Densités in situ et indices de réfraction. [Oceanic circulation. Densities in situ and indices of refraction.]** *Bull. Inst. Oceanograph. Monaco* 394. 26 p. 1921.

219. THOULET, M. J. **Sur la mesure directe des courants marins superficiels et profonds. [On the direct measurement of surface and deep marine currents.]** *Bull. Inst. Oceanograph. Monaco* 393. 4 p. 1921.

220. VAURABOURG, C. **La détermination de la densité de l'eau de mer par la mesure de l'indice de réfraction. [The determination of the density of sea water by the measure of the index of refraction.]** *Bull. Inst. Oceanograph. Monaco* 395. 27-47. 1921.

221. WHERRY, EDGAR T. **Soil acidity and a field method for its measurement.** *Ecology* 1: 160-173. 1920.—The author discusses the ways in which hydrogen ions may be produced in soils, a method of recognizing the cause of soil acidity, and describes the process of making indicator field tests for soil acidity. A color chart is included.—*Charles A. Shull.*

STRUCTURE, BEHAVIOR, SYMBIOSIS

222. ANONYMOUS. **Floral fireworks.** *Sci. Amer. Monthly* 3: 120. 1 fig. 1921.—A brief account is given of some of the methods of spore and seed distribution.—*Chas. H. Otis.*

223. BAILEY, IRVING W. **Some relations between ants and fungi.** *Ecology* 1: 174-189. 3 pl. 1920.—A number of species of myrmecophytes have been studied with special reference to the relations existing between the fungi found growing in the cavities inhabited by the ants, and the ants themselves. The growth and sporadic distribution of the fungi suggest that they are adventitious rather than cultivated by the ants. Investigation of the pellets found in the infrabuccal cavities of the worker ants showed that there is a general tendency among ants to take spores and fragments of mycelia into these cavities. The author believes that this infrabuccal sac serves mainly as a receptacle for food-residues and detritus rather than as a receptacle for food. The spores and fungi found in the cavity may be looked upon as detritus since the crops and stomachs of the ants never show spores or fragments of hyphae among their contents. While the ants are closely associated with fungi, the data presented do not indicate that the Formicidae other than the Attii, are fungivorous. The pure cultures of fungi often found in such ant homes may be the result of natural selection permitting one form to become dominant, after which it is transferred to new nests by the queens. The Formicidae are probably active agents in disseminating fungi, especially in the tropics. There is a brief discussion of the origin of fungus-growing and fungus-feeding habits of ants.—*Charles A. Shull.*

224. BUTLER, H. **Dendrobium linguiforme.** *Australian Nat.* 4: 207. 1921.—The structure of its leaf is regarded as explaining its xerophytic habitat.—*T. C. Frye.*

225. BUTLER, H. *Erythrina indica*. Australian Nat. 4: 206. 1921.—It is suggested that the species does not fruit in the vicinity of Sydney because a species of bird extracts the nectar by perforating the base of the flower.—T. C. Frye.

226. FORREST, GEORGE. A lecture on recent discoveries of rhododendrons in China. Rhododendron Soc. Notes 2: 3-23. 1920 [1921].—The author, who has spent 10 years in the botanical exploration of southwestern China, gives an account of his discoveries as they concern the genus *Rhododendron*. Introductory remarks on the topography and geology of the region are followed by notes on the environment, the habit, the flowers, and other obvious characters of a large number of species, many of them shown by lantern-slides in the course of the lecture. After the conclusion of the lecture I. B. BALFOUR made some remarks on the phylogenetic development of the genus and attributed its remarkable segregation in that region chiefly to the diversified climatic conditions. He further spoke on the relationship of the rhododendrons of these regions to lime in the soil and particularly on the important discovery of Forrest that the nitrogen-supplying mycorrhiza, which does not flourish in limestone soil, is replaced by a mycophyllon,—a fungus mycelium growing on the under side of the leaves and probably absorbing free nitrogen from the atmosphere and making it available to the rhododendron.—Alfred Rehder.

227. FORSAITH, C. C. Anatomical reduction in some alpine plants. Ecology 1: 124-134. 1920.—A study of the anatomy of *Betula glandulosa* Michx., *B. alba* var. *cordifolia* (Regel) Fernald, *Alnus crispa* (Ait.) Pursh, and *Rhododendron lapponicum* (L.) Wahlenb. from near timberline on the Presidential Range in New Hampshire, as compared with the anatomy of allied species from lower elevations, reveals a marked reduction of the medullary ray storage tissue in the alpine forms. In *Betula* and *Alnus* the rays are usually reduced to a uniseriate condition, and the compound rays of *Rhododendron* are markedly reduced. The reduction is believed due to the alpine climate. As the general trend of evolution of anatomy in these genera appears to be toward simplified rays, the notable reduction in alpine species seems to indicate that the severe conditions of alpine life cause a more rapid phylogenetic progress than occurs in sheltered lowland species.—Charles A. Shull.

228. GOOR, A. C. J. VAN. Das Wachstum der *Zostera marina* L. [The growth of *Zostera marina*.] Ber. Deutsch. Bot. Ges. 38: 187-192. 1920.—The author presents measurements, taken at 7 stations in the Watten Sea along the Dutch Coast over a period of 15 months, of minimum, maximum, and mean leaf width and length of the longest leaves of a large number of *Zostera* plants, of which the mean number of leaves is also given. The increase in leaf number by the development of new leaves, the decrease through dying off of old leaves, the growth of the new leaves in length and width, and the relation of these changes to the seasons of the year are discussed.—R. M. Holman.

229. HARRISON, J. W. HESLOP. The colors of primroses. Nature 107: 359-360. 1921.—Red-flowered forms transferred from one locality at 1,500 feet elevation to near sea-level produced red flowers the 1st year, but normal yellow ones thereafter. From another station at 1,000 feet the red was retained. Among hundreds of primrose-cowslip hybrids the author has never seen similar plants. The pollinating insect is *Bomblyllus major*.—O. A. Stevens.

230. HAVILAND, F. E. Some notes on *Kochia villosa*, Lind.: var. *tenuifolia*, F. v. M. Australian Nat. 4: 205-206. 1920.—Foliage and pollination are discussed from an ecological point of view.—T. C. Frye.

231. KLUGH, A. BROOKER. Nature's diary. Farmer's Advocate 56: 648. 1921.—*Hepatica* does not secrete nectar, but insects visit the flowers to obtain pollen.—F. W. L. Sladen.

232. LOWE, H. J. Bees and scarlet runner beans. Nature 107: 684. 1921.—The writer has previously reported [Nature 105: 742. 1920] bumble bees regularly puncturing the base of

the flower to obtain the nectar. In 1921 they did not. He suggests that the dry season has decreased the depth of the flower and perhaps hardened the calyx, making it more difficult to penetrate.—O. A. Stevens.

233. PERRYCOSTE, F. H. The colors of primroses. *Nature* 107: 459. 1921.—On the island of Sark an abundance of white, pink, and red primroses occur. Red could not have been due to altitude.—O. A. Stevens.

VEGETATION

234. ADAMS, CHARLES C., GEORGE P. BURNS, T. L. HANKINSON, BARRINGTON MOORE, and NORMAN TAYLOR. Plants and animals of Mount Marcy, New York. Part II. Ecology 1: 204-233. 6 fig. 1920.—Part II of this paper deals with the ecological relationships of the animals and plants of Mount Marcy. The fir forest is continuous over the slopes of Mount Marcy except for a bog at Tear Lake and the alpine summit. Conditions at the lower limit of the fir forest (4,250 feet) are described, with a list of plants in order of frequency. The vertebrate fauna, especially the birds, is listed and conditions favorable for animal life are discussed. The conditions at Tear Lake, the source of the Hudson River, are presented in detail, many plants and invertebrate animals being listed. The dwarf fir forest just below timber line (4,890 feet) is marked off abruptly from the alpine fell-field, and at timber line the trees are 7-12 feet tall. The undergrowth is made up mainly of mosses, with *Oralis acetosella* and a few other herbs among them. The forest is so dense that no true alpine plants penetrate through the timber-line barrier. Some invertebrates are mentioned from this forest, and a number of birds, with the plants that yield them food. The alpine zone receives major consideration. The succession is traced from the pioneer lichens to the climax vegetation of the alpine summit. A description is given of a dwarf birch meadow in which lowland species have pushed into the alpine zone. Another meadow on the south east side of the mountain (5,100 feet) shows a remarkable intrusion of lowland species into the alpine region. Invasion from above downward is found only at Tear Lake, but lowland species do not similarly find timber line a barrier to their distribution.—Charles A. Skull.

235. ANNANDALE, N., and H. G. CARTER. Notes on the vegetation of Seistan. *Jour. Asiatic Soc. Bengal* 16: 267-297. Pl. 4. 1919.—Plants collected at Seistan on the Persian frontier of Afghanistan and Baluchistan are listed, with an ecological discussion of the various types of vegetation observed: the stony desert, banks of saline streams, alluvium, sand dunes, etc.—E. D. Merrill.

236. ASTRE, GASTON. Contribution à l'étude de la répartition des zones biologiques sur les dunes méditerranéennes du golfe du Lion. [Contribution to the study of the distribution of the biological zones of the Mediterranean dunes of the Gulf of Lyons.] *Compt. Rend. Acad. Sci. Paris* 172: 1120-1123. 1921.—The author replies to a recent paper by Kühnholtz-Lordat [see Bot. Absts. 12, Entry 240]. The region is divided into 4 zones according to the general classification of dune areas made by the author, namely: abiotic, oligobiotic, mesobiotic, and pleistobiotic. The 1st is free from plants; the 2nd is characterized by *Ammophila arenaria* almost exclusively; the mesobiotic has in addition *Teucrium* and *Ephedra*; and the pleistobiotic is characterized by the presence of many plants.—C. H. Farr.

237. DWYER, J. W. A floral survey of the southwestern slopes of N. S. Wales round about Temora and Barmedman. *Australian Nat.* 4: 212-224. 1921.—A list of the plants by families is given with some remarks on their habitats.—T. C. Frye.

238. HAMILTON, A. A. An ecological study of the saltmarsh vegetation in the Port Jackson District. *Proc. Linn. Soc. New South Wales* 44: 463-513. Pl. 17-30. 1919 [1920].—A critical survey, based on detailed observations of the behavior of the vegetation of a definite area is given. The flora shows representative, successful, xerophytic modifications such as succulence, special breathing organs, glossy leaf surfaces, or reduced, cutinised, or vertically set leaves, shallow rooting, or massed arrangement, as means for resisting the principal factors

considered, namely; salinity of soil, intense insolation, imperfect drainage, and tidal and stream movements. The manner of formation of the marshes, their zonation, the means of seed distribution, the different groups of plants represented, their succession, and the part each plays in land formation are described. The scarcity of mosses and of rosette- and bulb-forming species, and the lack of bright colored flowers (associated with the wind pollination—found chiefly—instead of insect pollination) and fruits were noted in contrast with the bright flowered xerophytes of the sandstone hills. Red, as compared with green, *Salicornia* stems were present in all tufts and at all seasons but were least so in summer. The danger of mistaking the ecologic responses of a species for different species or varieties is pointed out. The formations discussed were (1) tide-flood zone, (2) a dry salt plain, and (3) fluvial zone.—*Eloise Gerry.*

239. HARPER, ROLAND M. The limestone prairies of Wilcox Co., Alabama. *Ecology* 1: 198–203. 2 fig. 1920.—A general discussion of the limestone soils of Wilcox county is accompanied by a list of the commonest species of plants found in the natural prairies.—*Charles A. Shull.*

240. KÜHNHOLTZ-LORDAT, G. Phytogéographie dynamique des dunes du golfe du Lion. [Dynamic plant-geography of the dunes of the Gulf of Lyons.] *Compt. Rend. Acad. Sci. Paris* 172: 865–868. 1921.—The dunes are rarely 60 m. wide and a maximum of 8 m. high. A triple dynamic action of wind, sand, and obstacles is involved. Plants, especially *Ammophila arenaria*, are concerned in the building of the dunes, and *Teucrium Polium* and *Ephedra distachya* are especially involved in conserving them. [See also Bot. Absts. 12, Entry 236.]—*C. H. Farr.*

241. MALTA, N. Oekologische und floristische Studien über Granitblockmoose in Lettland. [Ecologic-floristic studies of the mosses of granitic erratics in Latvia.] *Latvijas Augstskolas Raksti* [Acta Univ. Latviensis] 1: 108–124. 1921.—This article deals with mosses of Livonia and Kurland. Granitic erratics are interesting floristically because of the presence of montane species in the lowlands; ecologically, in the small, restricted, and unvarying character of the substratum they furnish, permitting easy recognition of the influence of climatic and other factors as well as facilitating study of changes in conditions produced by layers of humus, soil, shade, and moisture. Even very thin layers of humus cause such erratics to lose completely their distinctive character, hence care is necessary to distinguish the genuine granitic flora from that which has overrun the blocks.—In dry, sunny situations free from disturbance by men or cattle, the moss cover of granite blocks changes but little in the course of many years, even when the plant covering of the surrounding soil is greatly altered. Colonization of bare blocks proceeds from scattered plants finding lodgment in dust-filled depressions; speed is correlated with roughness of surface; lichens preceded mosses on smooth rocks. Various species of Grimmiaceae form the most conspicuous association covering rocks in open, sunny places; a 2nd well-defined association occurs on blocks in the shade of bushes; a 3rd, in the deeper shade of woods. The moisture factor is closely related to that of shade, but there is a well-defined hygrophytic association independent of the shade. Lists of species for each association are given. The article closes with an annotated list of 13 hepatics and 96 mosses which occur on granitic erratic blocks. A bibliography of 10 titles follows.—*E. B. Chamberlain.*

242. METCALF, Z. P. Some ecological aspects of the tidal zone of the North Carolina coast. *Ecology* 1: 193–197. 1920.—The paper deals principally with animals, but reference is made to several unnamed species of grasses and to *Uniola paniculata*, which occur on the tidal zone of the North Carolina coast.—*Charles A. Shull.*

243. NEEDHAM, J. G. A biological examination of Lake George, N. Y. *Sci. Monthly* 12: 434–438. 1921.—The water is "soft," and the dominant plants and lesser animals differ from those in other lakes in central New York. The most abundant plant is *Nitella opaca*, occurring at depths between 18 and 45 feet and covering scores, if not hundreds, of acres of the lake bed;

it is often 3-4 feet long, and is called grass locally. *N. batrachosperma* (at 5-foot depths) and 2 species of *Chara* are also present. Below the *Nitella* zone is the abundant siphon alga, *Dichotomosiphon*, at 40-50-foot depths. *Cladophora* is in the deep, dark areas. On the shore, *Tolypothrix* fairly covers the submerged stones. *Elodea* and hornwort are scarce. *Potamogeton praelongus* forms the most beautiful weed beds of the lake at 10-15 feet. Four genera of diatoms and other less abundant algae were found. Certain especially favorable collecting grounds are noted as are the small animals associated with certain plants.—*L. Pace*.

244. PEATTIE, DONALD C. An interesting habitat. *Rhodora* 23: 69-71. 1921.—A description is given of the flora and the habitat of an association for which the author proposes the name "Grotto," because of its resemblance to that physiographic feature. This habitat consists in a face or precipice of rock with frequently a sloping shelf below, and a continual seepage of water down the upper rock on to the lower. Owing to this seepage it is essentially a hydrophytic habitat yet an aerial one. An association of this type is detailed as it occurs in the Blue Ridge in North Carolina, and its annual cycle is described.—*James P. Poole*.

245. SOPER, J. DEWEY. Notes on the mammals of Ridout, District of Sudbury, Ontario. *Canadian Field Nat.* 34: 61. 1920.—The habitats of the local forest trees are briefly described.—*W. H. Emig*.

FLORISTICS

246. ANONYMOUS. Exhibit of National Herbarium specimens. *Proc. Linn. Soc. New South Wales* 45: 318-319. 1920.—*Eupatorium glandulosum* H. B. & K. and *Crepis setosa* Hall. were exhibited. The 1st is a native of Mexico, a garden escape, which has become well established in certain localities at sea level. The 2nd is a native of Europe and Asia Minor recorded for the 1st time in Australia. A seed of *Butia yatay* Becc. (*Cocos yatay* Mart.) which produced twin seedlings was exhibited. References to other cases of polyembryony are given.—*Eloise Gerry*.

247. BENNETT, ARTHUR. *Silene conica* L. in Carmarthenshire. *Jour. Botany* 59: 205-206. 1921.

248. CALVERT, E. W. Notes on the fauna and flora of East and Middle Sister and North Harbor Islands, Lake Erie. *Canadian Field Nat.* 34: 109-110. 1920.—A few of the more common trees are mentioned.—*W. H. Emig*.

249. COBAU, R. Flora vasculare spontanea della citta di Milane. [Flora of vascular plants of Milan.] *Nuova Gior. Bot. Ital.* 27: 89-128. 1920.

250. CULMANN, P. Muscinées spéciales à l'Auvergne. [Bryophytes peculiar to the Auvergne.] *Rev. Bryologique* 47: 65-69. 1920.—According to Héribaud there are 32 species of bryophytes, 13 hepatics and 19 mosses, which are restricted in France to the region of the Auvergne. The author shows that these numbers are much too high. On the basis of citations from the literature he is able to reduce them materially and expresses the opinion that the total number will hardly exceed half a dozen when the distribution of the bryophytes in France is more completely known.—*A. W. Evans*.

251. DESMIER, M. G. *Stereodon Haldani* Lindberg et *Alicularia compressa* (Hooker) Nees: deux nouveautés bryologiques pour la flore vosgienne. [Stereodon Haldani and Alicularia compressa, two bryophytes new to the Vosges Mountains.] *Bull. Soc. Bot. France* 66: 371-373. 1919.

252. DESPARTY, M. M. Nouvelles localités de plantes observées dans les cantons de Corbeil-Sud, de Milly-Nord (Seine-et-Oise) et de Melieu-Ouest (Seine-et-Marne). [New stations of plants found in the cantons of South Corbeil, North Milly (Seine-et-Oise) and West

Melun (Seine-et-Marne).] Bull. Soc. Bot. France 66: 334-338. 1919.—In this 2nd list 55 genera and 66 species are named.—A. Gershoy.

253. D[UNN], S. T. [Rev. of: GAMBLE, J. S. The flora of Madras, III. Kew Bull. 1920: 49-57. 1920 (see Bot. Absts. 7, Entry 2202).] Kew Bull. 1920: 75. 1920.

254. FARRER, REGINALD. Second expedition in Asia. (Cont.) The Akhyang Valley. Gard. Chron. 69: 162. Fig. 70. 1921.—A narration of the expedition is given with brief descriptions of the most interesting and attractive vegetation encountered. Earlier articles, published in 1919, 1920, and 1921, are listed.—P. L. Ricker.

255. FISCHER, C. E. C. Miscellaneous notes. Jour. Indian Bot. 2: 57-58. 1921.—New localities are recorded in peninsular India for *Pyrenacantha volubilis* Hook. and *Scoparia dulcis* L.—Winfield Dudgeon.

256. FLEISCHER, M. [Rev. of: MALTA, N. Beiträge zur Moosflora des Gouvernements Pleskau mit besonderer Berücksichtigung des Kalksteingebietes der Welikajamündung. (Contributions to the moss flora of the Government Pskov, with special reference to the limestone region at the mouth of the Velikaia River.) 78 p., 12 fig. Riga, 1919 (see Bot. Absts. 8, Entry 453).] Hedwigia 52: (Beiblatt) 30, 31. 1920.—The reviewer is inclined to confirm the author's statement that *Mnium hornum*, *Aulacomnium androgynum*, and *Grimmia pulvinata* reach their eastern limit in the Velikaia region and adds that *Pseudoscleropodium* (*Hypnum*) *purum* has a similar eastern limit.—A. W. Evans.

257. F[YSON], P. F. [Rev. of: HITCHCOCK, A. S. Floral aspects of the Hawaiian Islands. Ann. Rept. Smithsonian Inst. 1917: 449. 1919.] Jour. Indian Bot. 2: 152-153. 1921.

258. F[YSON], P. F. [Rev. of: WILSON, E. H. Notes from Australasia No. 1. Jour. Arnold Arboretum 2: 160-163. 1921.] Jour. Indian Bot. 2: 153-154. 1921.

259. HANSON, HERBERT C. Distribution of the Malvaceae in southern and western Texas. Amer. Jour. Bot. 8: 192-206. Fig. 1. 1921.—The geographical and ecological distribution of the Malvaceae in southeastern and in western Texas was studied; 66 species were found, 32 in the semi-tropical Gulf Strip, 4 in a small area of the Austroriparian, 35 in the Lower Sonoran, and 22 in the Upper Sonoran. Semi-tropical species of limited distribution are: *Bastardia viscosa*, *Malachra capitata*, *Abutilon pedunculare*, *A. jacquini*, *A. triquetrum*, *Wisadula periplocifolia*, and *Cienfuegosia sulphurea*. Western species of decidedly xerophytic type are: *Disella* spp., *Sphaeralcea* spp., *Sida* spp., *Abutilon malacum*, *Hibiscus denudatus* var. *involutus*, *H. Coulteri*, *Malvastrum coccineum*, and *M. elatum*. Eastern mesophytic species are: *Hibiscus lasiocarpus*, *H. militaris*, and *Kosteletzkya althacifolia*. Species of very wide distribution are: *Callirhoe involucrata*, *Malvastrum americanum*, *Malva parviflora*, *Sida diffusa*, *S. spinosa*, *S. hastata*, *Abutilon incanum*, and *Malvaviscus Drummondii*.—E. W. Sinnott.

260. KASHYAP, SHIV RAM. Notes on the distribution of liverworts in the western Himalayas, Ladak and Kashmir. Jour. Indian Bot. 2: 80-83. 1921.—Fourteen species were found in Jammu State, the surprisingly small number of 5 in the Kashmir Valley, and only 2 beyond the Himalayas north of Kashmir Valley. These observations bear out the previous conclusion of the author that in the Himalayas the number of species and individuals of liverworts decrease (1) in passing from east to west, (2) from south to north, and (3) from lower to higher altitudes.—Winfield Dudgeon.

261. MOUSLEY, H. Further notes on the orchids of Hatley, Stanstead County, Quebec, 1920. Canadian Field Nat. 34: 169-173. 1920.—Three additional species of orchids were found in the vicinity of Hatley. This brings the total number of species in this region to 33.—W. H. Enig.

262. PALMER, ERNEST J. *Botanical reconnaissance of southern Illinois*. Jour. Arnold Arboretum 2: 129-153. 1921.—The author states that the flora of southern Illinois contains many elements of the flora of the Gulf Coastal Plain, which extends at this point farther north than anywhere else in the continental interior. This fact is explained by the extension of the embayment of the Gulf of Mexico northward to southern Illinois up to the end of the Tertiary period and even later. The uplift of the Ozark plateau and the obliteration of the embayment caused great changes in the vegetation, but part of the original flora persisted in favorable localities. The plant associations of the different geological formations are given and the prominent species enumerated. A list of the ligneous plants observed with notes on their distribution, habitat, and habit concludes the article.—*Alfred Rehder*.

263. POTIER DE LA VARDE, R. *Bartramia stricta* Brid. sur le littoral de la Manche. [*Bartramia stricta* on the coast of the Manche.] Rev. Bryologique 47: 73. 1920.—The author reports his discovery of *Bartramia stricta* at St-Jean-le-Thomas, in the department of the Manche, France. The species is predominantly southern in its distribution, and its occurrence so far north is attributed to unusually favorable environmental conditions.—*A. W. Evans*.

264. RIDDELSDELL, H. J. *Draba muralis* in Gloucestershire. Jour. Botany 59: 180. 1921.

265. RÖLL, JULIUS. *Dritter Beitrag zur Torfmoosflora der Rhön*. [Third contribution to the peat moss flora of the Rhön.] Hedwigia 62: 155-162. 1921.—The present report is based largely on explorations made by the author during the summer of 1919 in the Rhön Mountains of Germany. The bogs of the region show few peculiar species, but the presence of *Sphagnum fuscum*, *S. Wilsoni*, and *S. tenellum* is emphasized and attention is called to the absence of certain species, especially members of the *Subsecunda* group. In all, 28 species of *Sphagnum* are enumerated, many of which are represented by several varieties and forms. Definite localities are noted in each case.—*A. W. Evans*.

266. TAYLOR, WM. RANDOLPH. *Additions to the flora of Mount Desert, Maine*. Rhodora 23: 65-68. 1921.—A list is given of species collected by Macfarlane and the author in 1915 and by the latter in 1920. The list includes algae, bryophytes, and angiosperms. In some cases the localities are given and in others only the data as to abundance.—*James P. Poole*.

267. TÖLG, F. *Eine naturwissenschaftliche Studienreise in das Amanus-Gebirge (Alman Dag)*. [A scientific expedition in the Amanus mountain range.] Arch. Naturgesch. Abt. A. 85: 88-130. Fig. 1-11. 1919 [1920].—Observations, made on a journey during the spring and summer of 1914 in eastern Asia Minor, are recounted. These deal in large part with the flora, native and cultivated. The notes of the author, since deceased (April 8, 1917), have been edited with a foreword by JOSEF FAHRINGER. A bibliography of 28 titles is appended.—*C. E. Allen*.

268. UGOLINI, U. *Contributo alla flora del Tirole Cisalpina*. [Contribution to the knowledge of the flora of cisalpine Tyrol.] Nuova Gior. Bot. Ital. 27: 251-261. 1920.

269. VIGNOLE-LUTANI, F. *Contributo alla flora del circondarie di Alba*. [Contribution to the knowledge of the flora about Alba.] Nuova Gior. Bot. Ital. 27: 208-322. 1920.—A list is given of names and stations of the plants collected and the significance noted of the occurrence of some of these in the study of plant distribution.—*Ernst Arschwager*.

270. WARD, F. KINGDOM. *The distribution of floras in S. E. Asia as affected by the Burma-Yunnan Ranges*. Jour. Indian Bot. 2: 20-26. 1 map, 2 pl. 1921.—The Burma-Yunnan Ranges are a southerly-extending arc of mountains at the eastern end of the Himalayas and the western end of the West China mountains, forming the divide between the Salween and the Brahmaputra and Irrawaddy Rivers. This paper refers especially to the flora of the

southern end of the Ranges (26° N. lat., 98° 30' E. long.). The entire region is forested, and may be divided into: (1) Jungle, up to 5,000 feet, composed almost entirely of Indo-Malayan forms (*Dipterocarpus*, *Shorea*, *Hiptage*, *Elaeocarpus*, *Engelhardtia*, *Garcinia*, *Caryota*, *Calamus*, and *Ficus*, with many epiphytes, lianas, and tree ferns. (2) Temperate rain forest, 5,000–8,000 feet containing many large trees (*Schima*, *Gordonia*, *Bucklandia*, *Quercus*, *Magnolia*, *Acer*, and *Rhododendron*, an abundance of epiphytes, small herbs, and moss, few lianas, and a moderate undergrowth, mainly bamboo. (3) Conifer forest, 8,000–12,000 feet, with *Abies*, *Rhododendron emuldrum*, and bamboos dominant; a few other conifers appear locally; there are many shrubs and few lianas. Alpine meadows are occasionally met with at 9,000–11,000 feet. (4) An alpine belt.—These Ranges are specially rich in Ericaceæ, there being more than 50 species of *Rhododendron* alone.—The flora is a mixture of Indo-Malayan, Himalayan, Chinese, and endemics. The Indo-Malayan element preponderates at lower altitudes and up the river valleys, but fades out eastward in Yunnan. In modified form it extends eastward in a belt along the coast of China almost to the Yangtze. The Himalayan element is well represented at intermediate levels, less so at high levels. The Chinese elements are derived from 2 distinct sources: (1) from the higher ranges of western China, and confined to higher altitudes; and (2) from a curious "Burma-Yunnan" flora, rich in endemics, and restricted to the area lying between the Salween River valley, about 26° N. lat., and the eastern end of the Himalayas.—The author concludes that "the N. E. Frontier belt, and more especially the Mekong-Salween divide, is primarily a barrier, botanical and zoological, marking the eastern limit of the Indo-Malayan, or Oriental region, for at least 750 miles. Secondarily it is, or has been, connected in the north with the Himalayan ranges on the one hand, and with the great China divide on the other, serving both to keep them apart and to link them up to a common centre."—*Winfield Dudgeon*.

271. WILSON, E. H. Notes from Australasia. I. Jour. Arnold Arboretum 2: 160–163. 1921.—The author speaks of his first impression of the peculiar character of the Australian flora, describes the forest vegetation of Western Australia, and mentions the most important forest trees, chiefly *Eucalyptus*.—*Alfred Rehder*.

APPLIED ECOLOGY

272. ANONYMOUS. A serious mis-statement. Amer. Bee Jour. 61: 64. 1921.—An erroneous report, that grapes are valuable as a source of honey, is refuted.—*J. H. Lovell*.

273. ANONYMOUS. Honey from city shade trees. Amer. Bee Jour. 61: 149–150. 1921.—In the city of Washington there are 10,000 basswood trees within a radius of 2 miles from Iowa Circle. A beekeeper, who moves his bees into the city, gets an average of about 35 pounds per colony of basswood honey. The moving of bees to the city is a novel idea.—*J. H. Lovell*.

274. ANONYMOUS. The beekeeping industry of Florida. Beekeepers' Item 5: 13–14. 1921.—With better beekeeping methods and the eradication of bee diseases the outlook for beekeeping in Florida is very promising. Probably nowhere in the U. S. A. is there so large a number of colonies of bees within so small an area as in the tupelo swamps along the Apalachicola River. The north central portion of the state contains extensive areas of gallberry (*Ilex glabra*). In the central and southern parts orange and grapefruit groves present possibilities to the progressive beekeeper. In other sections black mangrove, coconut, saw and cabbage palmettos, and partridge pea are valuable honey plants.—*J. H. Lovell*.

275. ANONYMOUS. The Spanish needles as a honey producer. Amer. Bee Jour. 61: 90. 1921.—Honey from *Bidens aristosa* is reported by nearly every county in Kansas.—*J. H. Lovell*.

276. ANONYMOUS. Wild thyme in New York. Amer. Bee Jour. 61: 53. 1921.—*Thymus serpyllum* has established itself over several square miles at Prattsville, New York. The honey is light amber in color, with a good body and a very good flavor. During 25 years the honey flow has never entirely failed.—*J. H. Lovell*.

277. ALLEN, GRACE. **Beekeeping as a sideline.** Gleanings in Bee Culture 49: 94-95. 1921.—This is a popular description of insect- and wind-pollinated flowers.—J. H. Lovell.

278. ALLEN, GRACE. **Beekeeping as a sideline.** Gleanings in Bee Culture 49: 157-158. 1921.—This popular review of the main nectar-yielding plants of the U. S. A. gives distribution and time of blooming.—J. H. Lovell.

279. BALDENSPERGER, PH. J. **Lavender.** Amer. Bee Jour. 61: 147-148. 1921.—Three species of lavender grow in the Alps. *Lavendula Stoechas*, common in the lowlands and hills species up to 330 feet, grows 20 inches tall and blooms March-May. *L. latifolia* grows at a higher altitude (600-1,320 feet) on calcareous soil, and blooms June-July. Neither of these species yield as much honey as *L. officinalis*, which grows at an altitude of 1,300 feet. The arid mountains are covered with bushes, which furnish a most delicious honey of a yellowish color, and which peasants sell by the hundred kgm. to perfume manufacturers.—J. H. Lovell.

280. BALDWIN, F. M. **A successful experiment with package bees.** Domestic Beekeeper 36: 10-11. 1921.—At Mt. Vernon, Georgia, the long honey flow from maples is very valuable. It begins early and continues until fruit bloom, or from Jan. 3 to Feb. 20. The temperature in this locality rarely drops below freezing.—J. H. Lovell.

281. BALDWIN, F. M. **Granulated honey.** Domestic Beekeeper 35: 15-16. 1921.—These notes on the honey plants of Georgia include mention of velvet bean, which is extensively planted for forage and secretes nectar well in the fall.—J. H. Lovell.

282. BALDWIN, F. M. **The color and flavor of gallberry honey.** Dixie Beekeeper 3: 12-15. 1921.—Pure gallberry (*Ilex glabra*) honey is difficult to get in Georgia. It is yellow in color and has the flavor of magnolia bloom. It has been erroneously reported to resemble white clover honey.—J. H. Lovell.

283. BALDWIN, E. G. **The honey plant regions of Indiana.** Amer. Bee Jour. 61: 51-53. 2 fig. 1921.—The author presents a description and map of the honey-plant regions of Indiana. Eight regions are recognized: (1) The limestone soils in the northern part of the state are covered with a heavy layer of clay, gravel, and sand, the clovers being less reliable than 100 miles south of the Michigan line. (2) The best clover belt is along the Wabash River extending from Cass to Adams and Wells counties; basswood is also abundant in this section. (3) A fairly good clover region extends from the Ohio line to Fountain County on the west border; Indianapolis is near the center of this area. (4) The best sweet clover region occupies the eastern portion of the state. (5) Locust (*Robinia pseudacacia*) is an important source of surplus in southeastern Indiana. (6) In the extreme southwestern portion climbing milkweed (*Gonolobus laevis*) yields large crops of honey. (7) From Knox County northward to Vermilion County along the west border smartweed may be considered as the main source of surplus. (8) In the Kankakee Valley marshland Spanish needles (*Bidens aristosa*) is the principal honey plant.—J. H. Lovell.

284. BENDER, C. F. **Red clover as a honey plant.** Amer. Bee Jour. 61: 99. 1921.—During protracted hot weather honeybees in large numbers gathered nectar from mammoth red clover. The flow lasted for 2 weeks, and 7,000 pounds of comb honey were secured. The quality was excellent but the color was a little darker than that of white clover and the flavor a little stronger.—J. H. Lovell.

285. BURKHOLDER, WALTER H. **The effect of two soil temperatures on the yield and water relations of healthy and diseased bean plants.** Ecology 1: 113-123. 1920.—The 2 soil temperatures used were 18 and 26°C., the results showing many irregular variations. In general diseased bean plants (*Fusarium Martii Phaseoli*) transpired about 50 per cent as much as healthy plants, and a similar reduction in yield of seed occurred. If transpiration and yield

are taken as criteria, the soil temperatures appear to have very little effect on the severity of Fusarium root rot of beans. But low soil temperature decreases the yield of healthy plants considerably.—*Charles A. Shull.*

286. BURNS, W., and G. M. CHAKRADEV. An ecological study of Deccan grassland. Jour. Indian Bot. 2: 84-91. 1 pl. 1921.—Seven acres of severely overgrazed "worst Deccan grazing land" near Poona, western India have been leased as an experimental plot for studying the problem of improvement of pasture land ruined by excessive grazing. After fencing the area, parts were cultivated and sown with various wild grasses; other parts were left to regenerate spontaneously. Six-m. square permanent quadrats have been laid out in different consociations in the area and studied in detail. For purposes of comparison, 2 other permanent quadrats have been laid out in the adjacent unprotected area. It is expected that protection, either alone or combined with a minimum of treatment, will enable valuable wild forage grasses to become established, after which intelligent exploitation will be necessary to maintain the pastures in a productive state.—*Winfield Dudgeon.*

287. CANNELL. The honey plants of France. Amer. Bee Jour. 61: 236. 1921.—The honey flora of France includes lavender (3 species), thyme, sage, mountain pennyroyal (*Satureja montana*), heather, borage, thistles, and *Mula viscosa*. Cultivated honey plants are locust, orange, alfalfa, sanfoin, clovers, and fruit bloom. From 25 to 75 pounds of a fragrant golden honey is secured from *Lavandula spica* (probably *L. vera*). Rosemary (*Rosmarinus officinalis*) is a slow but sure yielder of a very choice honey; the famous Narbonne honey is partly gathered from rosemary. If lavender and rosemary grew well in America they would be valuable additions to the honey flora.—*J. H. Lovell.*

288. CARLING, A. *Phacelia tanacetifolia*. Western Honey Bee 9: 6-7. 1921.—Fiddle-neck was formerly abundant on the cattle ranges of southern California, but thousands of acres have been destroyed by grazing. In Sweden on 500 square m. of land 1 kgm. of *Phacelia* seed was broadcasted and harrowed in. By the middle of August the plants had reached maturity and were $\frac{1}{2}$ m. high. The plants began blooming 8 weeks after planting and continued for 4 weeks. Honeybees gathered the nectar from 3 a.m. to 9:30 p.m.; 50-60 kgm. of honey were secured. The honey was pale yellow, clear, and thin, and had an excellent flavor.—*J. H. Lovell.*

289. CLAUSTRE, R. *Apiarian flora. Malope*. Gazette Apicole 22: 41. 1921.—*Malope* is an annual species of mallow which secretes nectar freely and blooms from May to July and again from October to November. The flowers are about the size of those of creeping mallow but have brighter colors. The large rugose leaves wilt and fall when blooming begins. The pollen is ash-gray colored. As soon as *Phacelia* begins to bloom the flowers are much less frequently visited by bees. *Malope* sowed at Ax (Ariege, France) reduced the diameter of its flowers and almost doubled the surface of its leaves.—*C. P. Dadant.*

290. COLEMAN, GEO. A. Beekeeping in our California national forests I. Honey flora. Western Honey Bee 9: 51-54. 1921.—The list includes all native herbaceous plants, shrubs, and trees valuable for pollen and nectar, also introduced species which have escaped from cultivation and are likely to prove good honey plants. Longleaf willow (*Salix longifolia*) yields a dark honey and much pollen and blooms from January to March. This species ranges from the Arctic Circle to Lower California and ascends the Sierra foothills to an altitude of 4,000 feet. White willow (*S. lasiolepis*) yields an amber-colored honey with a pleasant flavor, also much pollen. It blooms from February to March and ranges from northern to Lower California, and is valuable for early brood-rearing. Nuttall's willow (*S. flavescens*) is the earliest blooming mountain honey plant. It grows in the northern Coast Ranges, the Sierra Nevada, and San Bernardino Mountains. Silky willow. Velvet willow (*S. sitchensis*) is also valuable for nectar and pollen. The cottonwoods and poplars (*Populus Fremontii*, *P. trichocarpa*, *P. tremuloides*) furnish a large amount of pollen. California wax myrtle (*Myrica californica*) and sweet bay (*M. Hartwegii*) are wind-pollinated shrubs visited by bees for pollen. Mountain birch (*Betula fontinalis*) yields early pollen.—*J. H. Lovell.*

291. COLEMAN, GEO. A. **Beekeeping in our California national forests II. Honey flora.** Western Honey Bee 9: 84-86. 1921.—California hazelnut (*Corylus rostrata*), white alder (*Alnus rhombifolia*), red alder (*A. rubra*), mountain alder (*A. tenuifolia*), wind-pollinated shrubs, furnish early pollen. Scrub oak (*Quercus dumosa*), blue oak or mountain oak (*Q. Douglasii*), and tanbark oak (*Q. densiflora*) are wind-pollinated trees from which bees gather much pollen. Scrub oak is abundant in the chaparral. From blue oak in Monterey County sufficient honeydew is gathered in September and October to winter bees. Honeydew is also found on coast live oak. Tanbark oak blooms in warm locations in June, but usually the flowers open from the latter part of August to October. Giant chinquapin (*Castanopsis chrysophylla*) and golden chinquapin—variety *minor* of the preceding species—yield during late summer and in the fall a light amber-colored honey of good quality.—J. H. Lovell.

292. COLEMAN, GEO. A. **Beekeeping in our California national forest III. Honey flora.** Western Honey Bee 9: 116-117. 1921.—Bush chinquapin (*Castanopsis sempervirens*) is important in the fall for pollen. Wild buckwheat (*Eriogonum fasciculatum*) is abundant on the mesas and mountain slopes of southern California. It ranks 3rd as a honey producer in its range, white and black sages ranking it. It blooms from April to November. The honey is light to dark amber and of good quality. There are a dozen other nectar-yielding species at various elevations from the sea coast to the summits of the Coast Range. Mountain knotweed (*Polygonum Bolanderi*) blooms from July to September and yields an amber-colored honey. Dotted smartweed (*P. acre*) blooms from June to the middle of September, yielding abundant but poor quality honey. Ice plant (Sea fig, *Mesembryanthemum equilaterale*), grows on dunes and cliffs from Marin County to San Diego County. The flowers open at mid-day throughout the summer. The honey is white and has a good flavor. Two species of *Clematis* and the common buttercup are valuable chiefly for pollen.—J. H. Lovell.

293. COLEMAN, GEO. A. **Beekeeping in our California national forests No. II. Honey flora. IV.** Western Honey Bee 9: 149-151. 1921.—California barberry (*Berberis pinnata*), rather common on the hills from San Francisco to Monterey, blooms in March and April. The honey is amber-colored and has a good flavor. California laurel, bay-tree, or Oregon myrtle (*Umbellularia californica*), is found in the cañons of the Coast Ranges from southern Oregon to San Diego; it blooms from December to March. The honey is dark amber, and is valuable for early brood-rearing. Cream cups (*Platystemon californicus*) is common throughout a large part of California, blooming from April to May and valuable for pollen. Matilija poppy (*Romneya Coulteri*), valuable for pollen, is found from Santa Maria River to San Diego County. California poppy (*Eschscholtzia californica*) yields abundant pollen. Western poppy (*Papaver californicus*) grows in the southern part of the state and is valuable for pollen. Two early blooming honey plants are the flowering currant (*Ribes sanguineum*) and common gooseberry (*Ribes Menziesii*). Chamise (*Adenostoma fasciculatum*) is the most abundant and characteristic shrub of the higher Coast Ranges and the Sierra Nevada. It frequently forms extensive thickets to the exclusion of all other vegetation. These thickets, known as "chemisals" or chamise brush, cover wide areas with a low dense growth of a uniform blue green color. Chamise yields a light amber honey of good quality. The wild raspberry (*Rubus leucodermis*) and the common blackberry (*Rubus vitifolius*) secrete much nectar and in good seasons yield a surplus of honey. Mountain mahogany (*Cercocarpus parvifolius*), a common chaparral shrub in the mountains, is valuable for nectar.—J. H. Lovell.

294. COLEMAN, GEO. A. **Beekeeping in our California national forests No. II. Honey flora. V.** Western Honey Bee 9: 182-184. 1921.—Oregon crab apple (*Malus rivularis*) blooms from May to June and yields a white delicious honey. Black haw (*Crataegus Douglasii*) in April and May is the source of a white honey. Christmas berry (*Heteromeles arbutifolia*) yields in July a reddish honey of good quality and pleasant flavor. Several species of cherries and plums yield a light colored honey of good flavor.—J. H. Lovell.

295. COMBES, R. [Rev. of: ANNET, E. Contribution à l'étude du palmier à huile. Le palmier à huile au Cameroun, variétés, culture, exploitation. (Contribution to the study of the oil-palm. The oil-palm of Kamerun, varieties, culture, and uses.) Thèse de Doctorat, Larose, éditeur, 11, rue Victor-Cousin, Paris.] Rev. Gén. Bot. 33: 398. 1921.

296. CRANE, J. E. Wild thyme in New York. Amer. Bee Jour. 61: 179-180. 1921.—Wild marjoram (*Origanum vulgare*) is an important honey plant in southwestern Vermont. It has been incorrectly called wild thyme. The question is raised whether the plant in New York described as wild thyme is not wild marjoram.—J. H. Lovell.

297. DADANT, C. P. Those honey plants from China. Amer. Bee Jour. 61: 22. 1921.—Rape (*Brassica Rapa*) in China yields an immense amount of nectar. The honeyflow lasts from the middle of April to the first of May. It is a profitable crop in Australia, where it is valuable for both pollen and nectar.—J. H. Lovell.

298. ENSIGN, G. L. Star thistle. Amer. Bee Jour. 61: 89. 1921.—*Centaurea solstitialis* is an important source of honey in the Sacramento and San Joaquin Valleys, California. It blooms from June 10 until heavy frosts.—J. H. Lovell.

299. FOX, ELIAS. Trees for honey. Amer. Bee Jour. 61: 64. 1921.—The box elder (*Acer Negundo*) is not only an excellent shade tree, but is also valuable for both nectar and pollen.—J. H. Lovell.

300. HABER, VERNON R. The honey producing possibilities in North Carolina. Amer. Bee Jour. 61: 217-218. 1921.—The flora of North Carolina is intermediate between those of the northern and southern states. The great variation in climate and altitude makes possible a large number of species. The state is divided into 3 well-defined regions: The Coastal Plain, the Piedmont Plateau, and the mountainous region.—The Coastal Plain is a vast area of lowland, the eastern half of which is not more than 20 feet above sea level. Swamps and lakes abound, and the coast-line is deeply indented by broad tidewater rivers, bays, and sounds. The normal average precipitation is 54 inches. The most important honey plants are the tupelos (*Nyssa biflora* and *N. aquatica*), gallberry (*Ilex opaca*), tulip-tree (*Liriodendron tulipifera*), rattan-vine (*Berchemia scandens*), and huckleberry. The tupelos and rattan-vine occur on thousands of acres of swampland; gallberry, holly, and huckleberry grow upon higher soils. This section offers the best opportunity for apiculture. Many apiaries range from 100 to 125 colonies of bees, and report an average surplus per colony of 45-50 pounds. The honey flow comes very early in the spring.—The mountainous area covers about 6,000 square miles. The summers are cooler and the winters are more severe than in the eastern part of the state. A magnificent forest of hardwood trees reaches its highest development in this region. Sourwood (*Oxydendrum arboreum*), most abundant on the eastern slopes of the Blue Ridge Mountains, is the most important source of honey. Basswood is common on the northern slopes of the larger mountains. Other valuable honey plants are tulip-tree, locust, maple, sumac, wild cherry, goldenrod, and aster. The honey-flow from the tulip-tree begins about May 15, and from basswood and sourwood the latter part of June. Most of the surplus honey comes from forest trees.—The intermediate region is occupied by the Piedmont Plateau; it is the agricultural section of the state. Sourwood is most abundant in the upper portion nearest the mountains. Among the more important honey plants are tulip-tree, clovers, persimmon, holly, sumac, fruit-trees, cow-peas, maple, blackberry, goldenrod, and aster. Aster yields a prolonged flow of nectar in autumn, and 25-30 pounds of surplus honey often being secured. The apiaries are rather small and many of the honey plants are not reliable every year though there is seldom a complete failure.—J. H. Lovell.

301. HADSELL, B. A. Nectar from alfalfa. Gleanings in Bee Culture 49: 363. 1921.—Many farmers ruin both the seed and honey crop of alfalfa by over-irrigation.—J. H. Lovell.

302. HASSLBAUER, A. M. **The honey crop conditions.** Beekeepers' Item 5: 15, 44, 76, 108. 1921.—Brief notes are given on the condition of Texan honey plants.—*J. H. Lovell.*

303. HASSLBAUER, A. M. **The honey crop conditions.** Beekeepers' Item 5: 140. 1921.—Pin wheel or marigold (*Gaillardia pulchella*), a well known honey plant in Texas, is confined chiefly to the black land and the adjoining limestone hills; it is rarely found on sandy or white clay soils. During the spring of 1921 in the vicinity of San Antonio, Texas, horsemint failed to yield much nectar, and the bees were dependent on marigold.—*J. H. Lovell.*

304. HOWARD, A., G. L. C. HOWARD, and A. R. KHAN. **Studies in the pollination of Indian crops.** Mem. Dept. Agric. India Bot. Ser. 10: 195-218. Pl. 5. 1919.—Methods of pollination of the following plants are given: San-hemp (*Crotalaria juncea* L.), pigeon pea (*Cajanus indicus* Spreng.), Java indigo (*Indigofera arrecta* Hochst.), Sumatran indigo (*I. sumatrana* Gaertn.), flax (*Linum usitatissimum* L.), Taramira or duan (*Eruca sativa* Lam.), Til (*Sesamum indicum* L.), Niger (*Guizotia abyssinica* Cass.), round podded jute (*Corchorus capsularis* L.), long podded jute (*C. olitorius* L.), Roselle (*Hibiscus Sabdariffa* L.).—*J. J. Skinner.*

305. KNABENSHUE, S. S. **Southern California honey prospects.** Western Honey Bee 9: 139. 1921.—In the spring of 1921 weather conditions in southern California were unfavorable to nectar secretion by orange bloom, and only a small surplus of honey was secured. Late rains ensure 50 per cent of a full crop of honey from the sages.—*J. H. Lovell.*

306. LIVINGSTON, T. W. **How far do bees fly for nectar.** Dixie Beekeeper 3: 17. 1921.—Bees do not usually fly more than 1 mile from the hive in gathering nectar, but occasionally store a surplus from flowers 3-4 miles distant. Italian bees on an island in Puget Sound gathered nectar from goldenrod on the mainland 5 miles away.—*J. H. Lovell.*

307. LOVELL, JOHN H. **A plant honeydew from the Douglas fir.** Amer. Bee Jour. 61: 93. 1921.—The author summarizes the observations of Davidson and Teit on the exudation of a sweet liquid by the tips of the leaves of *Pseudotsuga Douglasii*. A beekeeper at Victoria, British Columbia, reports 2-3 supers of sections are gathered in some seasons from this source. The honey is fair in quality, pale amber-colored, with rather dark cappings; it crystallizes early. It is a poor winter food.—*J. H. Lovell.*

308. LUSHER, A. E. **Fogs affect nectar secretion in sage.** Gleanings in Bee Culture 49: 362. 1921.—Sage yields nectar better in the fog belt than in the region beyond it.—*J. H. Lovell.*

309. MILLEN, F. ERIC. **Sweet clover as a honey plant.** Canadian Hort. and Beekeeper 29: 3-4. 1921.—The value of sweet clover (*Melilotus*) as a honey plant varies greatly with the locality. In the U. S. A. it has long been recognized as a valuable source of surplus. In Canada its value has not yet been determined. Possibly in Ontario the acreage of sweet clover in any one district is too small to yield large honey crops. Soil and weather conditions are also important factors affecting nectar secretion, examples being cited in alsike (*Trifolium hybridum*) and white or Dutch clover (*T. repens*). The following yields for sweet clover obtainable in Ontario are given; in 1 apiary a colony stored 23 pounds in 1 day; in another, 500 pounds were stored in 5 weeks. Thirty-two weak colonies gave 4,500 pounds surplus; and 88 packages gave 6,000 pounds surplus and increased to 99 colonies. In Ontario sweet clover honey is light in color and mild in flavor.—*F. W. L. Sladen.*

310. MORRIS, T. B. **Observations on horsemint.** Beekeepers' Item 5: 133. 1921.—The secretion of nectar by *Monarda punctata* is greatly affected by weather conditions.—*J. H. Lovell.*

311. OSTERHOUSE, G. W. **Rape.** Amer. Bee Jour. 61: 236-237. 1921.—Large fields of rape (*Brassica Napus*) are grown in the Netherlands. Beekeepers pay a good rent for locations near fields of blooming rape.—J. H. Lovell.

312. PARKS, H. B. **Effect of soils on honey flows.** Beekeepers' Item 5: 39-40. 1921.—Two centuries ago Della Torre noticed that bees visit plant species growing in one kind of soil, but do not visit the same species growing in another kind of soil. Sourwood (*Oxydendrum arboreum*) thrives on acid soils but not on limestone soils; buckthorn (*Rhamnus*) on the contrary is found on limestone soils. In New York white clover yields more nectar on limestone soils than on acid soils. In Texas the distribution of almost every plant is determined by the rock formation.—J. H. Lovell.

313. PELLETT, FRANK C. **Correct name for wild thyme.** Amer. Bee Jour. 61: 180. Fig. 1-4. 1921.—Wild thyme (*Thymus serpyllum*) and wild marjoram (*Origanum vulgare*) are often confused. Both are naturalized from Europe and both occur in New England and New York. A brief description is given of each species.—J. H. Lovell.

314. PELLETT, FRANK C. **Garden plants which attract the bees.** Amer. Bee Jour. 61: 175. 1921.—Many garden flowers,—bee balm, bachelor's button, marjoram, horehound, lavender, and mignonette,—are valuable sources of nectar. Among the vegetables, onions, celery, parsnips, and cabbage are good honey plants.—J. H. Lovell.

315. PELLETT, FRANK C. **The orange as a source of nectar.** Amer. Bee Jour. 61: 138. 1921.—The quality of orange honey is so high that it often commands a premium in the market. The groves of Satsuma oranges along the coast of Mississippi are not regarded as of much importance; likewise in Florida the orange yields nectar much less freely than in California. At Visalia, California, the flow is so heavy that the clothing of men engaged in cultivating the groves is saturated with nectar. A Tulare County beekeeper extracted 171 pounds of orange honey in 10 days. Near large orange orchards apiaries contain as many as 400 colonies. Along the coast the fogs are unfavorable and the flow is much lighter than in the interior.—J. H. Lovell.

316. REDWAY, JACQUES W. **An overlook of the relations of dust to humanity.** Ecology 1: 190-192. 1920.—The floating and wind-borne dust of the atmosphere is briefly discussed. The ecological relations of dust to disease-producing bacteria, especially in cities, are touched upon.—Charles A. Shull.

317. ROOT, E. R. **The call of the Southland.** Gleanings in Bee Culture 49: 206-209. 1921.—In the Coastal Plain of Virginia, North Carolina, South Carolina, Georgia, and Alabama the soils along the rivers and bays and in the swamps are acid and unfavorable to clovers. The most important honey plants are titi, gallberry, blackberry, huckleberry, and the tupelos, which flourish in acid soil. The best honey comes from gallberry (*Ilex glabra*) and is very similar in color, flavor, and body to that of white clover. Its quality is often impaired by the presence of titi honey. The tupelos are the source of an excellent white honey which never granulates. There are wonderful opportunities for beekeeping in this section, but the conditions are very different from those in northern states.—J. H. Lovell.

318. SANDERS, H. W. **Seasonable notes.** Domestic Beekeeper 35: 8. 1921.—The 1st honey flow of importance in the North [U. S. A.] comes in May from the dandelion. The honey is thick, yellow, and strong-flavored, with the odor of the dandelion. It is very valuable for stimulating brood-rearing.—J. H. Lovell.

319. SCHRELS, W. B. **Beekeeping in foreign lands.** Interesting facts about apiculture in little Costa Rica. Gleanings in Bee Culture 49: 146-148. 1921.—A list of the most important honey plants in Costa Rica includes citrus fruits, mesquite, almond, catsclaw, many vines, and tropical fruits. The honey flow begins with the dry season, which lasts 6 months; with the 1st rain, in April, the flow decreases.—J. H. Lovell.

320. SCULLEN, H. A. **Beekeeping in the State of Washington.** Amer. Bee Jour. 61: 96-97. 1921.—From the standpoint of bee culture the state may be divided into 5 distinct regions: (1) Yakima, Columbia, and Okanogan Valleys, and the district about Walla Walla, where the main honey plants are alfalfa and sweet clover; (2) arid region east of the Cascades, not yet under irrigation; (3) extreme northeastern part of the state where the annual rainfall is over 20 inches. The surplus comes from fireweed (*Epilobium angustifolium*), white clover, snow-berry (*Symphoricarpos*), dandelion, and alfalfa; (4) the east and southeast counties, where wheat-growing is the leading industry. White clover is the most important honey plant; (5) the largest region is that portion of the state west of the Cascade Mountains, where the annual rainfall varies from 20 to 200 inches. Fireweed is the leading honey plant, but white and alsike clovers, Oregon maple, vine maple, Cascara sagrada, huckleberry, and many others are important locally.—J. H. Lovell.

321. SHORTLIDGE, CHAS. B. **Coreopsis as a source of honey.** Amer. Bee Jour. 61: 66. 1921.—Along the Delaware River *Bidens trichosperma* and *B. laevis* are reliable honey plants. An average per colony of 20 pounds of extracted honey has been secured, with 20 pounds left in the hives for winter stores. The honey is light yellow and has a faint spicy odor and flavor. The plants are often called Coreopsis.—J. H. Lovell.

322. SLADEN, F. W. L. **Beekeeping in the North.** Canadian Hort. and Beekeeper 29: 4. 1921.—Conditions 200-300 miles north of the international boundary are described. Willows, blueberry (*Vaccinium canadense*), bluebell (*Mertensia paniculata*), wild strawberry, and Labrador tea (*Ledum groenlandicum*) are among the principal plants which build up the colonies in spring. Alsike, white clover, and fireweed (*Epilobium angustifolium*) are the principal sources of surplus honey. The spreading of alsike and white clover in the cleared districts of the clay belt in northern Ontario and northern Quebec augurs well for the future of beekeeping there. A fairly good honey crop is obtained from white clover around Dauphin, Manitoba, and Edmonton, Alberta, where it is moderately plentiful. The honey flow from clover, begins 2-3 weeks later in the north than in the south but lasts 4-5 weeks longer. Fireweed, which grows abundantly after forest fires, is scattered across the continent and is spreading as the land is cleared. For 4 consecutive years a good honey crop has been obtained at Melfort, northern Saskatchewan, mainly from fireweed. Fireweed honey flow is usually terminated abruptly about the end of August or the beginning of September by light frosts. Minor honey plants are asters, especially *Aster macrophyllus* (Ontario), goldenrod, (Quebec to Saskatchewan), anise (*Agastache foeniculum*), hyssop (Manitoba, Saskatchewan, and Alberta), and wild raspberry (Haileybury, Ontario). Aster honey when unripe has caused winter loss in northern Ontario. The north is particularly well adapted for beekeeping, as the warm days and cool nights favor nectar secretion, and the long working days increase the honey crop. In favorable seasons 200 pounds of clover honey per colony is common near Lake Temiskaming. At Roberval on Lake St. John, Quebec, an average annual colony-yield of over 200 pounds is obtained from alsike and white clover. July and August are the best honey-producing months.—F. W. L. Sladen.

323. SLADEN, F. W. L. **Fireweed or willow-herb; a great honey plant of the far North extending into this country in a few places only.** Gleanings in Bee Culture 49: 212-214. 2 fig. 1921.—*Epilobium angustifolium*, a native of northern North America and Eurasia, has a more northern range than any other important honey plant. In Canada it is most abundant in British Columbia, but it extends eastward to the Atlantic maritime provinces. It springs up abundantly on newly burned over forest land, but usually dies out after a few years. At Hector, British Columbia, it is found at an altitude of 5,200 feet. In a good fireweed locality a surplus of 500 pounds per colony has been obtained. At Montcerf, Quebec, the average annual yield per colony in a large apiary was about 100 pounds. In the Gatineau Valley the honey flow lasts from about July 10 to September 5. Fireweed is propagated both by seed and by rootstocks. Solitary stalks of a white-flowered variety were observed in a stand of fireweed at Monteith, Ontario. The honey is almost water white, has a mild flavor, and granu-

lates after extraction.—High up in the mountains of British Columbia there is another species, *E. latifolium*, which has broader leaves and larger flowers, but is less than 1 foot tall.—*J. H. Lovell*.

324. SMALL, A. V. Sources of Kansas honey. *Amer. Bee Jour.* 61: 62-63. 1921.—Alfalfa and sweet clover are the principal honey plants. The secretion of nectar by alfalfa is affected by altitude.—*J. H. Lovell*.

325. TOCHUDIN, ERNST. Nectar secretion affected by altitude. *Gleanings in Bee Culture* 49: 100. 1921.—The intense radiation at high altitude stimulates the secretion of nectar. The average honey production per colony, according to statistics prepared by the French Departement des Pyrenées, is as follows: from sea level to 1,000 feet, 6 pounds, 10 ounces; from 1,000 to 2,000 feet, 8 pounds, 3 ounces; from 3,000 to 4,000 feet, 15 pounds, 7 ounces; from 4,000 to 5,000 feet, 19 pounds, 13 ounces.—*J. H. Lovell*.

326. VOHIES, CHAS. Mexican palo-verde. *Gleanings in Bee Culture* 49: 162. 1921.—Mexican palo-verde or "bogota" (*Parkinsonia aculeata*) is abundant on the university campus, Tucson, Arizona. It is a native of Mexico and extends into Arizona in the extreme southwest for a short distance only. A part of the first crop of honey comes from this source. The quality of the honey is good.—*J. H. Lovell*.

327. WEST, G. F. Beekeeping in sunny Alberta. *Western Gardener and Poultry Jour.* 2: 77-78. 1921.—Beekeeping conditions at Medicine Hat, Alberta, Canada, are discussed. Irrigation projects are being installed and some are in operation. Alfalfa (*Medicago sativa*) when grown on irrigated land in this vicinity will yield an enormous crop of honey. Wolfberry (*Symphoricarpos occidentalis*) also contributes a part of the crop, and there is at times a twang of bergamot honey (*Monarda mollis*). Gumweed (*Grindelia squarrosa*) grows in large patches, but no bees were seen working on it, and the honey does not have the objectionable flavor attributable to this plant.—*F. W. L. Sladen*.

328. WILDER, J. J. Flora for comb honey. *Dixie Beekeeper* 2: 12-14. 1921.—Among the best regions for the production of comb honey in the Southeast are the Black Belt of Mississippi, central Florida, southeast Georgia, and along the Apalachicola River in northwestern Florida.—*J. H. Lovell*.

329. WILDER, J. J. Pepperbush. *Dixie Beekeeper* 2: 15-16. 1921.—*Clethra alnifolia* yields a light amber-colored honey with good flavor and body. In southeast Georgia this shrub makes beekeeping around the great swamps possible. It furnishes all of the winter stores and maintains brood-rearing during a period when it would otherwise cease. A surplus is obtained in some localities. It begins blooming July 1 and continues until late fall, but the flow is never very heavy.—*J. H. Lovell*.

330. WILDER, J. J. Sourwood as a honey plant. *Dixie Beekeeper* 2: 10-12. 1 fig. 1921. *Oxydendrum arboreum* is the most important honey plant of the Blue Ridge section of the southeastern states. It not only grows on the mountain sides and on the hills of the Piedmont Plateau but also along streams of the Coastal Plain. In the lowlands the bees gather no nectar from it. While it is common on the mountains it never forms a dense growth. It does not yield well every year, and in some seasons no surplus is obtained. The best crop ever secured was an average of about 100 pounds per colony. The honey is almost water white, with heavy body and mild delicious flavor.—*J. H. Lovell*.

331. WILDER, J. J. Summer farewell. *Dixie Beekeeper* 3: 3-4. 1921.—Aster is very abundant on the sandy soils of northern and central Florida. The honey is almost water white and has an excellent flavor and good body. It granulates at the beginning of cold weather. A surplus of 30-50 pounds per colony is often obtained, but 150 pounds have been removed from a single colony.—*J. H. Lovell*.

332. WUST. *Bienennährpflanzen mit schneller Vermehrungsfähigkeit für Imkergärten.* [Honey plants, which grow and spread rapidly, for the beekeeper's garden.] *Bienenflege* 43: 42. 1921.—Garden plants of special value for honey are noted and described.—*M. G. Dadant.*

333. ZEISS. *Der Götterbaum.* [Tree of Heaven.] *Bienenflege* 43: 60. 1921.—The value of *Ailanthus glandulosa* for shade and honey is discussed. It blooms in central Europe from June 5 to 25, and is a good honey producer.—*M. G. Dadant.*

FOREST BOTANY AND FORESTRY

Introduction. GRUNSKY, C. E. Hydrographic phase—the hydrography of San Francisco Bay. KOFOID, CHARLES A. Biological phase—the marine borers. HUNT, G. M., and C. L. HILL. Engineering phase—pile protection materials and methods. 104 p., 36 pl. 1921.] *Nature* 109: 426-428. 1922.

341. ALGAN, H. Nos bois coloniaux. [Our colonial woods.] *Bull. Trimest. Soc. Forest. Franche-Comté et Belfort* 14: 271-279. 1922.—A résumé is given of 2 pamphlets by André Bertin, who estimates that France will require importations of wood at the rate of 8 million cubic m. per year for the next few years. This amount can best come from the French colonies of the Atlantic, where the forests cover 60 million hectares,—12 million in the Ivory Coast, 30 million in Gabun, 12 million in Kamerun, and 5 million in Guiana. The 30 million hectares additional in Madagascar and Indo-China are too far away. Since the war a study has been made of the special qualities and usefulness of 500 species of trees from the colonies. A table indicates those suitable to replace species now in use. They are classified as substitutes (1) for poplar and yellow poplar, (2) for pine and fir, (3) for oak and teak, (4) for beech, hornbeam, and sycamore, (5) for elm, ash, and acacia, (6) for cabinet woods, and (7) for woods suitable for railroad ties, mine props, piles, etc. The common names, scientific names, country in which produced, average density, and characteristic color of each wood are given. The forests contain on the average 60 trees per hectare of 30 cm. diameter and over, with a volume of 250 cubic m., of which 150 cubic m. can be utilized. A plan for the management of the colonial forests will place at least 40 per cent of the total area of each colony under government control. Concessionaires will be obliged to leave in every parcel cut over a specified number of seed trees of desirable species.—*J. Kittredge, Jr.*

342. ALGAN, H. Sur la densité des sapinières. [Concerning the density of fir forests.] *Bull. Trimest. Soc. Franche-Comté et Belfort* 14: 242-244. 1922.—An indication as to what should be the normal number of stems per hectare of a given size in a complete and regular stand of fir may be secured as follows: 2 trees of equal diameter d grow at a distance apart trunk to trunk of D , such that $D = 10d + 1$ m. If the neighboring trees are not of the same diameter, the average of their diameters should be used for d . Assuming that a fir tree covers an area S equal to the square of the diameter of its crown, then $S = (10d + 1)^2$, and the number of trees per hectare will be $N = \frac{10,000}{(10d + 1)^2}$. A table is given based on this equation showing the number of trees per hectare from 10 to 60 cm. diameter breast high. It also gives for each diameter class the basal area per hectare. For various causes the increase in material is suspended when the stems measure from 40 to 45 cm. diameter breast high and the stand approaches $\frac{2}{3}$ of its normal volume at maturity.—*J. Kittredge, Jr.*

343. BARBEY, A. L'épicéa et la sécheresse de 1921. [Spruce and the drought of 1921.] *Bull. Trimest. Soc. Franche-Comté et Belfort* 14: 237-241. 1922.—The facts are outlined which caused the recent dying of spruce. Spruce requires considerable atmospheric humidity and frequent summer rains and consequent fresh soils to thrive and resist insect attacks. In introducing it on plains and shallow soils with summer droughts there is danger from droughts or from accompanying insect damage, such as occurred in 1907, 1911, and 1921. The bark beetles, weevils, long-horned beetles, and buprestids attack trees in full vitality only in exceptional cases. Brief descriptions are given of the attacks of *Tomicus typographus*, *T. chalcographus*, *Hylesinus polygraphus*, *Pissodes harcyniae*, *Collidium luridum*, and *Anthaxia quadripunctata*. The remedies are: avoid introducing spruce at low elevations in dry climates, and encourage the development of full-crowned trees without serious crowding or shading. If the trees are attacked they should be cut and the bark removed and burned at once.—*J. Kittredge, Jr.*

344. BOURNE, R. A dissertation upon forest finance. *Indian Forester* 48: 1-14. 1922.—The theory that the short rotation for forest crops for Indian species is most profitable is challenged and a detailed working out of the formula shows that the longer rotation gives the greater financial return. Examples are given to support the author's contention.—*E. N. Munns.*

345. BOUTILLY, V. La cause de la déformation des cèdres dans l'Atlas mitidjien. [The cause of the malformation of the cedars in the Atlas Mitidjen Mountains.] Bull. Sta. Recherches Forest. Nord Afrique 1: 218-221. Fig. 1-3. 1921.—*Cedrus atlantica* occupies a limited area about 8 km. long by 2 or 3 km. wide along the crest of the Atlas chain, at about the elevation of Blida. The forest is characterized by the deformation of all the old trees, which have lost their terminal shoots to have them replaced by several laterals, which results at the age of 30 or 40 years and over in a form of tree with numerous bayonet-like trunks which are useless for logs. The young trees less than 50 years old are straight and do not have this form. Within the last 3 or 4 years there has been a serious epidemic of a weevil (*Thaumatopoea pityocampa*) which has killed the leading shoots. Apparently this was the cause of the deformation of the older trees 50 years ago.—J. Kittredge, Jr.

346. BROOKS, A. The breaking strain of timbers. Agric. Gaz. New South Wales 32: 463. 1921.—The breaking stress of red ironbark [*Eucalyptus sideroxylon*], grey box [*E. hemiphloia*], and cypress pine [*Callitris* sp.] is compared with American white pine [*Pinus Strobus*].—L. R. Waldron.

347. BROWN, NELSON COURTLANDT. The place of utilization in American forestry. Jour. Forestry 20: 135-138. 1922.—Because of the great savings in the consumption of wood which are possible through the use of lower grades, better usage of materials, more careful methods in manufacture, and the use of wood preservatives, more attention should be given by the schools to forest utilization. Some schools are working to that end now, but more stress should be placed upon the subject as more and more men are entering the lumber industry.—E. N. Munns

348. BROWN, W. H. Minor products of Philippine forests. Forest. Bur. Philippine Is. Bull. 22¹. 432 p., 28 pl. 1920; 22². 410 p., 73 pl. 1921; 22³. 329 p., 26 pl. 1921 [1922].—This comprehensive, copiously illustrated work makes readily available a previously undigested mass of economic data on Philippine economic plants. The work is published in 3 volumes, each complete in itself, the 3rd presenting a complete index to all local and scientific names. The subjects covered are mangrove swamps, palms and palm products, bamboos, fiber plants, sources of paper pulp, resins, gums and oils, wild food plants, natural dyes, ornamental plants, soap substitutes, official medicinal plants, poisonous plants, miscellaneous useful plants, edible fungi, and medicinal uses of Philippine plants. Certain subjects have been treated by specialists, such as E. D. MERRILL, O. A. REINKING, LEON MA. GUERRERO, A. F. FISHER, and A. P. WEST.—E. D. Merrill.

349. C., S. Z. Der Ertrag der sächsischen Staatsforsten. [Yield of Saxony state forests.] Deutsch. Forstzeitg. 37: 381. 1922.—The production of the state forests decreased 11 per cent during the decade 1837-1846 in spite of a slight increase in area. In succeeding decades the stock was increased considerably, amounting to 27,000,000 cubic m. in 1873; at that time the rotation was lowered. Heavy cuttings caused deterioration of site conditions, and this, together with smoke from industrial plants and difficulties in securing natural reproduction resulted in a present growing stock nearly 15 per cent below normal. To restore a normal stock within a period of 25 years will require a net increase of 120,000 cubic m. per annum, and since the increment is 620,000 cubic m. this will permit an annual cut of 500,000 cubic m.—W. N. Sparhawk.

350. CHAMPION, F. W. The conversion of coppice and coppice-with-standards to high forest. Indian Forester 48: 15-22. 1922.—The arguments for and against conversion of coppice forests are listed. Those against conversion are listed as financial, economic, and technical. Under Aubert's system, which is given in detail, most of the disadvantages disappear. It is practicable and economical and is particularly applicable to areas of good quality coppice in which the inroads of the war upon the standards have been heavy.—E. N. Munns.

351. CHUN, W. Y. *Chinese economic trees*. xxviii + 309 p, 100 pl. The Commercial Press: Shanghai, China, 1922.—Brief descriptions of about 300 species are given. In many genera additional species are listed or mentioned. One hundred species are figured. New names are *Phoebe chinensis* Chun (*P. macrophylla* Gamble, non Blume), *Hicoria cathayensis* (Sargent) Chun (*Carya* Sargent), and *Amelanchier sinica* Chun (*A. asiatica* var. *sinica* Schneider).—*E. D. Merrill*.

352. COUPIN, HENRI. *Les forêts au point de vue biologique*. [Forests from the biological standpoint.] *La Nature* 50²: 157-159. 1922.

353. DAVIS, W. M. *Lower California and its natural resources*. [Rev. of: NELSON, EDWARD W. *Lower California and its natural resources*. Mem. Nation. Acad. Sci. [U. S. A.] 16: 1-194. 1921.] *Geog. Rev.* 11: 551-562. 1921.—In this review the main emphasis is on geologic and geographic features with some mention of the forests and other types of vegetation, such as grassland and desert.—*S. B. Shaw*.

354. DAWKINS, C. G. E. *Big Hnaw* (*Adina cordifolia*) and *teak trees*. *Indian Forester* 48: 108-110. 1922.—The measurements of 2 large trees are given; the Hnaw was 23 feet 6 inches in girth at 4.5 feet and the teak 18 feet 2 inches in girth.—*E. N. Munns*.

355. DESCOMBES, PAUL. *La forêt régulatrice et génératrice des eaux*. [The forest as a regulator and generator of waters.] *Rev. Eaux et Forêts* 59: 139-142. 1921.—Forests affect the waters in 2 ways: (1) by making their flow more regular, and (2) by increasing their abundance through dews and mists which are deposited in a considerably greater quantity on foliage than on bare soil. The 1st influence has been scientifically demonstrated by the Swiss forest experiment station [see *Bot. Absts.* 9, Entries 710, 1232]. It was well illustrated in 1875 by floods in the Onne and the Pique, 2 adjacent streams the watersheds of which are practically identical except that the former is about 5 per cent, the latter about 40 per cent forested. The Onne increased its discharge with great suddenness and violence from 11 to 130 cubic m. and caused a damage of several hundred thousand francs, whereas the Pique increased its discharge much more gradually from 8 to 46 cubic m. and caused a damage of not more than 6,000 francs.—The influence of the forest in increasing the abundance of waters was investigated some 60 years ago by an engineer who reported that the discharge of springs is twice as much in forested as in deforested areas, and that reforestation can increase the discharge of springs by 7 cubic m. per day for every hectare reforested. Subsequent investigations have shown that the amount of water deposited by dews and mists in forested watersheds sometimes exceeds that coming from rainfall. In the 2 streams cited, it is regarded as fair to assume that the much greater annual discharge of the Pique (1,732,000 cubic m. per square km. as against 693,000 for the Onne) is due solely to the fact that the watershed of the former is 40 per cent and the latter only 5 per cent wooded. In this region the amount of water coming from unseen condensations in the forested areas is 5 times that coming from rainfall; reforesting $\frac{1}{3}$ of a watershed would double the discharge of its waters.—*S. T. Dana*.

356. DWIGHT, T. W. *Timber administration of the Dominion Forest Service*. *Jour. Forestry* 20: 4-9. 1922.—Some 22 million acres are under the Dominion Service, which is responsible for keeping these lands productive. Careful lumbering is insisted upon, and to reduce fire danger the brush is piled and burned concurrently with the logging work. Cutting is supervised in order to insure natural reproduction. Two nurseries supply trees for prairie and forest planting, the prairie planting having been successfully encouraged for 20 years.—*E. N. Munns*.

357. GALLAND, P. *Rétablissement des forêts dévastées par la guerre*. [Re-establishment of the forests devastated by the war.] *Bull. Trimest. Soc. Forest. Franche-Comté et Belfort* 14: 72-75. 1921.—The forests in the district of Saint-Dié were badly mutilated, in some cases considerable areas being completely destroyed. The dead wood should be utilized

at once, both to effect economy and to facilitate planting. In some places leveling the ground must precede planting. Trenches and dugouts have caused an increase in floods and a serious problem in the erosion and deposition in valleys. When the ground surface has been re-established it is planned to plant fir in the proportion of at least 80 per cent where there is some shrubby vegetation for protection. Lacking this, seed of *Genistae* will be sown to provide shade, in which fir seed will be sown or nursery stock 15 to 18 cm. high planted, spaced 2 m. apart.—J. Kittredge, Jr.

358. GLASSON, A. K. Mortality of sal in Buxa Division, Bengal. Indian Forester 48: 22-32. 1922.—The abundance of dead sal was found to be due to the overflowing of rivers, and heavy mortality from climbers, windfall, and insects. Regulation of the cut, a revised scheme of creeper cutting, and insect control reduced the amount killed. The fungus *Polyporus Shoreae* was found to be causing damage, but the investigations of its action have not been completed. This fungus promises to be a serious factor in plantations.—E. N. Munns.

359. GRANT, MADISON. Saving the redwoods. Nation. Geog. Mag. 37: 519-536. 10 fig. 1920.—A discussion of the forests of *Sequoia sempervirens* in northwestern California and southern Oregon is given with a description of the life habits of the tree. A plea is made for the preservation of these forests.—W. M. Atwood.

360. HAUSENDORF. Der Langenbrander Schirmkeilschlag von Forstmeister Dr. Eberhard und der Wagnersche Blandersaumschlag in Gaildorf. [The Langenbrand shelterwood-wedge system of Dr. Eberhard and the Wagner border-strip felling in Gaildorf.] Zeitschr. Forst.-u. Jagdw. 53: 474-482. Fig. 1-3. 1921.—Witzbach and the author visited both areas. Witzbach prefers Eberhard's system, for 3 reasons: it provides the forester with more managerial freedom, makes better use of the road system, and under it the silver fir at Gaildorf can be more easily retained. Hausendorf finds no basis for comparison, since it is not possible to compare an organic whole, the border-strip system, with a part of such a whole, the wedge system, the only object of which is to secure improved methods of removing timber from the forests. Advantages and disadvantages of the Wagner system are discussed.—J. Roesser.

361. HAWLEY, R. C., E. I. TERRY, and K. W. WOODWARD. Forest region and type classification for New England. Jour. Forestry 20: 122-129. 1922.—This report of a committee divides New England into 3 regions and specifies for each the types, with a description of the composition, origin, location, and importance of each of the forest types. Seven tree types are recognized, which are classified by topographic conditions, species, mixtures, or importance.—E. N. Munns.

362. HENRIEY. Le hêtre à Plancher-les-Mines. [Beech at Plancher-les-Mines.] Bull. Trimest. Soc. Forest. Franche-Comté et Belfort 14: 76-79. 1921.—An account is given of marking, the forest being composed of fir in mixture with beech or in mixtures with fir, beech, ash, maple, and elm; the last 3 are favored in the marking. Beech is marked more heavily than fir because the latter is utilized for lumber and dimension stock and has a higher value. Beech is of inferior quality and is used little except for firewood. The proportion of species in this forest is: fir 37 per cent, spruce 17, beech 34, and miscellaneous hardwoods 12. Beech occupies more space than fir of equal diameter and, hence, has a smaller volume per unit of area. The growth of fir forest, after the trees are over 60 cm. in circumference, is more than 5 times that of the beech forest.—J. Kittredge, Jr.

363. HOLMGREN, A. LEO. Stormhärjningen Hösten 1917 å Älvdalens Besparingsskog. [A storm in the Älvdal forest in the autumn of 1917.] Skogsvårdstidn. Tidskr. 19: 172-178. Fig. 1-3. 1921.—The article gives an account of the damage wrought by a severe storm in Dalarne, Sweden. Tables and graphs show the number of windfalls and damaged trees by species, diameter, and height classes.—G. A. Pearson.

364. HOWARD, S. H. **Thinnings.** *Indian Forester* 48: 110-112. 1922.—An answer is given to some of the criticisms of thinning methods. It is not necessary to make heavy thinning in a stand which has been thinned from the beginning, but it is necessary when previous thinnings have been neglected.—*E. N. Munns.*

365. HOWE, C. D. **Our forest conditions and some of our forestry problems.** *Ann. Rep. Quebec Soc. Protection Plants* 14: 23-30. 1922.—“Briefly our forest conditions present this problem: Shall we accept for our lumbering and pulpwood industries the wood of constantly decreasing quality which nature unguided produces when the equilibrium in the forest has been upset by fire, disease or logging operations, or shall we exert intelligent effort to maintain our pine, spruce, and other valuable forests and thus supply the forest industries with wood of incomparable quality particularly adapted to their needs?”—*B. T. Dickson.*

366. JOANNIS, J. DE. **Les chenilles des cônes de cèdre.** [The cone weevils of cedar.] *Bull. Sta. Recherches Forest. Nord Afrique* 1: 187-199. *Pl.* 19-20. 1921.—Various species of the genus *Dioryctria* which seriously damage the Algerian cedar are described.—*J. Kittredge, Jr.*

367. KHAN, ABDUL AZIZ. **Charcoal making in the Central Provinces.** *Indian Forester* 48: 102-104. *Pl.* 7. 1922.

368. MER, ÉMILE. **Possibilité par volume.** [Regulation by volume.] *Bull. Trimest. Soc. Forest. Franche-Comté et Belfort* 14: 6-24. 1921.—Regeneration cuttings are not suited to the fir forests of the Vosges Mountains because the winds are too violent, the cutover areas are too readily invaded by brush, and the fir is not sufficiently fertile. Sustained yield should be abandoned for it constitutes, especially in irregular stands, an obstacle to cultural operations which too often cannot be undertaken in time to be effective. There results a serious loss of production. With the sustained yield the regulation by volume, which serves only to establish it, would also disappear. The cutting cycle should be so arranged that blocks are cut over on short rotation at frequent intervals so that mature trees can be exploited where they are too numerous, thinnings made in young stands, young growth disengaged, and openings planted.—*J. Kittredge, Jr.*

369. MILLAR, W. N. **Status of forestry in western Canada.** *Jour. Forestry* 20: 10-17. 1922.—The work of the past 5 years by foresters in western Canada is reviewed in which the progress in administration, protection, and development are outlined. The 3 most important developments are the disposal of slash, cooperative live-stock grazing, and the use of the airplane patrol in fire protection. Other work which has been developing more slowly includes forest and utilization investigations, nursery practice, forest surveys, and the establishment of a forest school.—*E. N. Munns.*

370. NOWACK, ERNEST. **A contribution to the geography of Albania.** *Geog. Rev.* 11: 503-540. 1921.—In an extended description of Albania the forest, brushwood, maqui, and heath vegetation are discussed in relation to altitude and precipitation.—*S. B. Shaw.*

371. OSMASTON, A. E. **The mensuration of plantations.** *Indian Forester* 48: 74-78. 1922.—The ordinary formulas given for the number of plants per acre do not include the space left at the edges of these areas and the increased growth secured by border trees. New formulas are developed and examples given for determining correctly the true number involved.—*E. N. Munns.*

372. PEUTZ, VON. **Die Entwicklung der Klenganstalten in den letzten 25 Jahren.** [The development of seed-extracting establishments in the last 25 years.] *Zeitschr. Forst- u. Jagdw.* 53: 257-277. *Charts* 1-5. 1921.—A description is given of the seed-extracting establishments of Eberswald, Annaburg, and Klausenau constructed within the past 25 years which

shows the improvement from the compartment or box type of kiln to the cylindrical kiln with preliminary drying chambers. Haack's experiments show that the danger to which the seed is subjected by the heat in drying is directly proportional to the percentage of moisture in the cones. It has also been established that the origin of the seed is of great importance, even though the climatic variation in Prussia does not exceed 1°C. Seed from different sources should be kept separate. Small extracting establishments are desirable and to avoid the old compartment form a "safety seed extracting kiln" has been placed on the market for small operators. This is described and illustrated in detail. Its chief feature is 3 drying compartments: the upper, where the cones are subjected to 40°C until $\frac{1}{4}$ open; the middle, where 50°C is maintained until the cones are $\frac{3}{4}$ open; and the drum proper where a temperature of 55°C is maintained until all seed is removed. The capacity of this establishment is about 2,000 kgm. of seed during the operating season from Dec. 15 to May 1. It has marked advantages over the old method of seed extraction and the health of the operator is not impaired by working in intense heat and dust.—*J. Roeser, Jr.*

373. PRATT, MERRITT B. *Shade and ornamental trees of California.* 130 p., 137 pl. California State Bd. Forest. 1922.—A description is given of 152 native and exotic trees with large plates of the more important ones planted in California. Species suitable for planting in different localities in the State are listed by regions.—*E. N. Munn.*

374. R[ECKNAGEL], A. B. [Rev. of: BRUCE, DONALD. *A white fir volume table.* California Agric. Exp. Sta. Bull. 329. 41-45. 1921.] *Jour. Forestry* 20: 75. 1922.

375. R[ECKNAGEL], A. B. [Rev. of: FISHER, RICHARD T. *The management of the Harvard Forest, 1909-1919.* Harvard Forest Bull. 1. 27 p. 1921.] *Jour. Forestry* 20: 75-77. 1922.

376. RECKNAGEL, A. B. [Rev. of: HAASIS, F. W. *Relations between soil type and root form of western yellow pine.* Ecology 2: 293-303. 1921.] *Jour. Forestry* 20: 147-149. 1922.—While the author did not find a correlation between growth water and root form, the general character of the root system is induced by the conditions under which the tree has developed. Branching and different root forms are more the result of external conditions than the response to soil. Root competition in the semi-arid regions is worth considerable study as it is probably of more importance than the light relationship.—*E. N. Munn.*

377. REYES, TERESO. *La agricultura de Mexico esta en peligro de desaparecer a causa de la destrucción de los bosques.* [Mexican agriculture in danger of disappearing because of the destruction of the forests.] Rev. Agric. [Mexico] 6: 275-280, 338-343, 396-397. 4 fig. 1921.—Popular.—*John A. Stevenson.*

378. ROGERS, WALTER E. *Ice-storms and trees.* Torreya 22: 61-63. 1 fig. 1922.—Two ice-storms occurring in central Wisconsin in February and March, 1922, were studied with regard to their effect on forest trees. Twigs of 13 trees were compared as to increase in size due to ice, ranging from 950 per cent in *Tilia americana* to 226 in *Quercus alba*. Twigs of 21 species showed a weight of ice varying in its ratio to the weight of the twig from 132:1 in *Ulmus americana* to 5:1 in *Quercus rubra*. Leaves of *Q. alba* showed a weight of 44:1, and needles of *Pinus laricio* 95:1. Wide variation in amount of damage was observed.—*J. C. Nelson.*

379. SCHAEFFER, A. *Comment les forêts s'enrichissent.* [How forests enrich themselves.] Bull. Trimest. Soc. Forest. Franche-Comté et Belfort 14: 269-270. 1922.—Data are given to show the results of marking in the Haute-Saône in 1883-85 and in 1921. The number of coppice stems reserved on an area of 112,000 hectares has been increased from 72 to 82 per hectare, of small standards from 34 to 78, and of large standards from 5 to 10. At the same time the average number of trees sold and cut per hectare has been increased from 40 to 56. Thus the forestry ideal of increasing growing stock and at the same time increasing yield has been realized.—*J. Kittredge, Jr.*

380. SCHAEFFER, [A]. *La sylviculture en Haute-Saône*. [Silviculture in the Haute-Saône.] Bull. Trimest. Soc. Forest. Franche-Comté et Belfort 14: 244-248. 1922. [A verbatim reprint of a publication of the Agricultural office of the Prefecture of Haute-Saône.]—The forests of Haute-Saône occupy 31 per cent of its area. Most of them are managed as coppice under standards, which is particularly suitable for private owners because both saw timber and firewood are produced. Marking is the most important operation in these forests. Since charcoal wood has fallen in price, the marking of coppice trees to be reserved should be made heavier, up to 200 or 300 per hectare. All vigorous standards should also be reserved. Cleanings are very desirable where possible. In the small woods of high forests, thinnings should be made every 6 or 8 years, by which 2 or 3 times the production of wood can be secured. The introduction of fir in the coppice stands on poor sites in the mountains should be encouraged. A fir forest may always be expected to yield twice as much revenue as one of oak. The sterile, uncultivated fields of the hill country should be reforested with carefully selected species. Poplars can be planted to good advantage in marshy lands along streams.—*J. Kittredge, Jr.*

381. SEAMAN, L. N. *Note on the relative strength of spruce red wood and spruce white wood (Picea morinda)*. Indian Forester 48: 34-42. Pl. 3-4. 1922.—Two tests were made to determine the strength of spruce for railway sleepers, one to determine spike-holding power, the other to establish strength, stiffness, and toughness. Red wood, the dense of the 2, proved the better for this purpose.—*E. N. Munns.*

382. SEURRE. *Les forêts françaises et les bois de papeterie*. [French forests and wood for paper pulp.] Bull. Trimest. Soc. Forest. Franche-Comté et Belfort 14: 229-236. 1922.—The French paper pulp industry consumes annually about 3,150,000 steres (stacked cubic m.) of wood. The French forests occupy at present an area of 10,100,000 hectares, of which 74 per cent is coppice and the rest high forest. The woods suitable for manufacture of paper pulp are spruce, fir, Scotch pine, black pine, Austrian pine, aspen, birch, poplars, and Eucalyptus. The fir and spruce forests have an area of 950,000 hectares, the average annual growth being 3-4 cubic m. per hectare; $\frac{3}{10}$ of this, —1,282,500 cubic m.,—would be available for paper pulp. The pine forests cover 285,000 hectares. Growth averages 3 cubic m. per hectare per year, $\frac{3}{4}$, —285,000 cubic m.,—being available for paper pulp. Aspen occurs in the proportion of $\frac{1}{10}$ in the coppice forests, occupying 3 million hectares. The growth of these forests is 2 cubic m. per hectare per year, and $\frac{1}{2}$ of the aspen, —300,000 cubic m.,—is available annually for paper pulp. Birch can furnish 80,000 cubic m. additional. Poplars will furnish 100,000 and Eucalyptus 20,000 cubic m., so that the total production of wood for paper pulp is estimated at 2,117,500 cubic m. as compared with a consumption of 2,079,000 cubic m. France may, therefore, be expected to be self-supporting in pulpwood production. A recent process indicates that maritime pine, after a preliminary extraction of the resin, can also be used for paper pulp. This would make available an additional 905,000 cubic m. of pulp wood.—*J. Kittredge, Jr.*

383. SPAETH, J. NELSON. *Notes on the release of white pine in Harvard Forest, Peter-sham, Massachusetts*. Jour. Forestry 20: 117-121. 1922.—Disengagement cuttings show a marked response in white pine as in 5 years the per cent of normal healthy trees increased from 39 to 51; where no cuttings were made the per cent dropped from 51 to 22. The general health of white pine when released showed 28 per cent improved and 44 per cent the same, while without release only 3 per cent were improved and but 14 per cent remained the same. Damage other than suppression is due to the loss of terminal growth by whipping, especially in the winter season. Release is most successful when the pines average about 12 feet in height for site 2.—*E. N. Munns.*

384. STEBBING, E. P. *The forests of India and the development of the Indian Forest Department*. Indian Forester 48: 81-98. 1922.—The early history of the forestry movement in India is traced with the causes which led to the changes in the forest management. The perfected organization has developed a great resource and made the service one that can stand as a model for the British Empire.—*E. N. Munns.*

385. SUTHERLAND, JOHN. **Forestry in its national and economic aspects.** Jour. Forestry 20: 93-105. 1922.—The lack of appreciation of the United Kingdom of forests was responsible for the great shortage of timber during the war. Forests were permitted to grow as remnants of an original culled forest in small patches or in still smaller areas as plantations of various native and exotic species. Recently the Forestry Commissions have been authorized to undertake a program of afforestation which in 10 years is to cover 150,000 acres. Altogether 1,770,000 acres are to be reforested and $\frac{2}{3}$ of this amount is recommended as the aim for the next 40 years. Private capital and enterprise are to be stimulated into caring for forests through perhaps some form of subsidy, relief from taxation, protection against fire, disease, and insects, which would call for regulation of cutting later. While this area would not satisfy all local demands, it would conserve shipping, help exchange, retain capital, and help to solve a problem of the development of rural areas.—*E. N. Munnis.*

386. TRABUT, L. **Utilisation des Eucalyptus dans le Nord de l'Afrique.** [Utilization of eucalyptus in Northern Africa.] Bull. Sta. Recherches Forest. Nord Afrique 1: 202-210. 1921.—Eucalyptus woods, chiefly of *E. globulus*, grown in north Africa have met with unjustifiable disfavor. *E. rostrata*, *E. rudis*, *E. teretincornis*, and more rarely *E. punctata*, *E. collossea*, and *E. diversicolor* have been planted. As an example of the possibilities of Eucalyptus wood, the author gives the results of planting operations and successful utilization of different species of *Eucalyptus* in California, including use for railroad ties, marine piling, telegraph poles, boards, cabinet wood, and firewood. *E. occidentalis* var. *astringens* is being exploited largely in Australia for tannin, of which it yields more than *Acacia*. Eucalyptus is also useful for planting in wet and brackish soils. Crosses are frequently more resistant and grow more rapidly than the non-hybrid species. Recommendations are included of the most suitable species for planting in northern Africa.—*J. Kittredge, Jr.*

387. WALKER, A. H. **Thinning of deodar.** Indian Forester 48: 78-80. Diagr. 1922.—Measurements of deodar heavily thinned show that the tree can be released from suppression and that it will respond quickly to the stimulus of an open stand.—*E. N. Munnis.*

388. WATIER, CH. **Les Cupressinées dans le Maroc méridional.** [Cupressineal in southern Morocco.] Bull. Sta. Recherches Forest. Nord Afrique 1: 222-240. 1921.—*Callitris quadrivalis*, *Juniperus phoenicea*, *J. Oxycedrus*, *Cupressus sempervirens*, and *Argana sideroxyylon* form the most important part of the forest flora of southern Morocco. They occur under similar conditions and in the same localities, but usually with one or other of the species dominant. Each has a wide altitudinal range and is indifferent to aspect. Differences in the mineral constituents of the soil apparently account for the fact that in a good locality one of these species usually attains superiority and the others are eliminated. For each of the conifers a discussion is given of the characteristics of the tree and of the forests and their occurrence in the region. The forests of *Callitris* are the most important at present. Many of these forests are being heavily tapped for the resin, which is the basis for sandarac. The possibilities of exploiting these forests, the cultural operations which should be undertaken, the economic advantages, and the by-products,—particularly sandarac,—are discussed. A table is given of the exportations of this gum to foreign countries from 1913 to 1917.—*J. Kittredge, Jr.*

389. WEBSTER, A. D. **The Sitka spruce in Sussex.** Gard. Chron. 71: 79. 1922.—Notes are given on a planting of 14 acres made at Sussex about 1908.—*P. L. Ricker.*

390. WEIBECKE. **Ostdeutscher Kiefernwald. Seine Erneuerung und Erhaltung.** [East German pine forests. Their renewal and retention.] Zeitschr. Forst- u. Jagdw. 53: 294-305. 1921.—The subject of seed cultures is taken up under the sub-headings (1) soils upon which sowing can be done, (2) time of sowing, and (3) the seed. Sowing of forest seed is generally practicable. Poor results are avoided to the extent that sparse and valuable humus is conserved, collected, and mixed in the drill furrows. The necessity of planting occurs on only

about 10 per cent of the cultural areas. Soil impoverishment may be combated by (1) water conservation through early soil preparation, (2) prompt seasonal sowing in the spring, (3) packing of forest litter as a fertilizer. Pine seed must be in the soil by the 10th or 15th of April, when there is the desired soil moisture and temperature. Pine seed swells in 8-10 days at 10-15°C.; it germinates best when the sun heats the soil to 20-25°C. for a few hours daily. Nurseries should be sown about April 8 and planting done between March 25 and April 15, at the latest April 25. Only once in 31 culture years has the author lost an early sowing on a sunny site by frost-killing of the germinating seed. The best seed is obtained from cones allowed to open naturally, collected from fellings in advanced pole-wood and in mature stands. If stands have been thinned and branchy material removed, good origin and heritage is assured. Commercial seed extracting establishments often deliver seed of various germinative powers collected in different years, all intermixed. This is allowed as long as the guaranteed germinative power is obtained from the whole. It is recommended that every forest superintendent collect his own seed from fellings and thinnings in mature and pole stands over 60 years old. Cones collected earlier contain unripened seed.—*J. Roesser, Jr.*

391. WICKENHEISER, HERBERT C. Notes on a growth of young white birch. *Torreyia* 22: 84-86. 1922.—A cinder-filled swamp area at the south end of Van Cortlandt Park in New York City is occupied by a growth of *Betula populifolia* Marsh. About 1000 trees are found over an area of 10 acres. The average height is 24½ inches, and diameter of stems 6 inches above the ground ¼ inch. The tallest are about 5 years old, dating back to the filling-in of the swamp. The nearest birch trees are about ½ mile to the north.—*J. C. Nelson.*

392. WILSON, ELWOOD. Forest mapping and estimating from aerial photographs. *Jour. Forestry* 20: 113-116. 1 fig. 1922.—A hydroplane was used in making a survey of 140 square miles of forest land away from communication. The flying done at 5000 feet gave very accurate results when checked against ground studies. Costs under this method were less.—*E. N. Munns.*

393. WOOD, B. R. Artificial regeneration of sal in Gorakhpur. *Indian Forester* 48: 53-67. 1922.—Sowing and planting of sal has been attempted for 8 years, and observations show that sal seed has considerable vitality if placed ¼-½ inch in moist earth. Without proper moisture sal lies in the soil several months before germinating. Root and shoot planting is a failure, but great success followed seed sowing in the forest. Sal apparently prefers full light and responds readily to it, though able to persist where the shade is not too heavy.—*E. N. Munns.*

394. WOOLSEY, T. S. JR. Public forestry on private land. *Jour. Forestry* 20: 130-134. 1922.—Forest devastation can probably be best stopped by direct federal control; the second best means is by federal cooperation with state agencies. But where unimproved forest land is neither being devastated nor intelligently managed there should be some method of state protection and improvement at the risk of the holder. An act for this purpose is given which provides for the necessary management of certain private land with and without the application of the holder; the return of the property after a minimum period with reimbursement for necessary outlays; the purchase of the land if the costs are not paid.—*E. N. Munns.*

395. WOOLSEY, T. S. JR. [Rev. of: BENSKIN, E. Afforestation in the United Provinces. Government Press: India, 1921.] *Jour. Forestry* 20: 146. 1922.—The erosion in the Gangetic Plain resulting from deforestation makes necessary reforestation methods similar to those used in the French Alps. Forest planting is progressing slowly and so far has been successful.—*E. N. Munns.*

396. WOOLSEY, T. S. JR. [Rev. of: BLOLEY, H. E. L'aménagement des Forêts par la méthode expérimentale et spécialement la méthode du contrôle. (Forest management by the experimental method especially the method of control.) 90 p. Attinger: Paris, Date?] *Jour.*

Forestry 20: 144-145. 1922.—The forests of silver fir should be managed as an experimental area and be constantly under observation in order to determine maximum growth.—*E. N. Munns.*

397. W[oolsey], T. S. Jr. [Rev. of: FISHER, RICHARD. T. *The management of the Harvard Forest, 1909-1919.* Harvard Forest Bull. 1. 27 p. 1921.] Jour. Forestry 20: 77-78. 1922.

398. W[oolsey], T. S. Jr., and R. Z[on]. *Forest mensuration.* [Rev. of: CHAPMAN, HERMAN H. *Forest mensuration.* xxii + 553 p. J. Wiley and Sons: New York; Chapman & Hall Ltd.: London. 1921.] Jour. Forestry 20: 139-144. 1922.—The book is designed for school use and is far superior to other works so far published. Discussions of older methods and illustrations should be included in an appendix as some of the subject matter is apt to be confusing. The use of the board foot in American work is decidedly unfortunate as it brings into the mensuration work many difficulties in calculation.—*E. N. Munns.*

399. WRIGHT, H. L. *Forest fires caused by landslips.* Indian Forester 48: 110. 1922.—A fire was seen starting in dry grass which could have been caused only by sparks from falling rocks in a landslip.—*E. N. Munns.*

400. ZAVITZ, E. J. *Reforestation in Ontario.* Jour. Forestry 20: 18-24. 1922.—Two problems of reforesting are involved, private lands in southern Ontario, Crown lands in the Laurentian plateau. On private lands, remittance of taxes, education, demonstration areas, and tree distribution from governmental nurseries are responsible for a growing appreciation of what can be done. Municipal forests are being established, the management being turned over to the provincial foresters. On the Crown lands reliance has been placed on natural regeneration, but this has not proved sufficient and must be supplanted by artificial means.—*E. N. Munns.*

401. ANONYMOUS. *Growth and sex-factors of racial character.* Nature 109: 389. 1922.—An abstract is presented of a paper read by Miss R. M. FLEMING at the Royal Anthropological Institute Feb. 28, 1922, with report of a brief discussion.—*O. A. Stevens.*

402. ANONYMOUS. *Prof. Rolfs writes of unique citrus trees in Brazil.* California Citrogr. 7: 13. 1921.—P. H. ROLFS, in a letter to A. D. Shamel, describes briefly a "freak" orange tree found at Morro Velho, Brazil. Several branches bear fruits with "etiolated" or colorless segments, but the leaves are normal.—*Howard B. Frost.*

403. ANONYMOUS. *A new view of fertility.* [Rev. of: PELL, C. E. *The law of births and deaths: being a study of the variation in the degree of animal fertility under the influence of the environment.* 192 p. T. Fisher Unwin: London, 1921.] Nature 109: 267-268. 1922.

404. ADAMS, C. D. *Avocado varieties committee submits new report.* California Citrogr. 7: 310-311, 322. 1922.—In connection with descriptions of varieties it is stated that it is increasingly probable that the "ideal" type of avocado will result from hybridization between the Guatemalan and hardy Mexican types. Some such hybrids have already been produced.—*Howard B. Frost.*

405. ANDERSON, W. S. **Vitality of spermatozoa.** Kentucky Agric. Exp. Sta. Res. Bull. 239. 36 p. 1922.—(1) The vitality of the spermatozoa of some domestic animals. The semen of a fertile horse contains numerous active spermatozoa. When a number of inactive spermatozoa are present in semen, it is an indication of partial sterility. The presence of a considerable proportion of inactive spermatozoa is invariably an indication that a large percentage of females mated will not conceive. Certain males produce an abundance of sperms all inactive. A considerable number of males were found in which no sperms could be found in the semen. Under laboratory conditions at temperatures varying from 0 to 46°C. spermatozoa usually did not remain active for over 8 hours. The period of activity is only slightly greater after normal insemination. The addition of acid in small quantities to semen reduces the activity of the sperm. The average pH value of the semen of 7 normal males was 7.31 and of 5 sterile males 7.58. (2) The vitality of the spermatozoa of some sea animals. The spermatozoa of the oyster (*Ostrea virginica*) and the hard shell clam (*Venus mercenaria*) are immobile in the sex glands and the seminal fluid but become active in contact with sea water; sodium chloride is the activating agent. Dilute alkaline solutions are apparently not injurious to the spermatozoa. The spermatozoa are active in a 15 per cent solution of ethyl alcohol in salt solution. Very dilute solutions of acids are injurious to the spermatozoa.—W. D. Valleau.

406. BREMER, G. **Een cytologisch onderzoek van eenige soorten en soorts-bastaarden van het geslacht Saccharum.** [A cytological research of some species and species hybrids in the genus *Saccharum*.] Arch. Suikerindust. Nederland.-Indië; Mededeel. Proefsta. Javasuikeerindust. 1. 111 p., illus. 1922.—In growing sugarcane seedlings at the Sugar Experimental Station at Pasoeroean, Java, species hybridisation has been carried on for many years. Crossings were made between genuine wild species of *Saccharum* (for instance *S. spontaneum*) and the usually cultivated varieties of *S. officinarum*, but some wild varieties were also used which are probably species hybrids.—The author found that the species of this genus hitherto examined have different chromosome numbers, and that a classification based on the chromosome numbers corresponds with one based on outer morphological characteristics.—The author found that the haploid number of chromosomes in pollen mother cells of *S. spontaneum*, a wild growing species, is 56. The reduction division occurs in a normal way. In 5 special varieties of *S. officinarum*, which differ widely from one another in outer characteristics, the haploid number is 40, but frequently a varying number of these chromosomes do not conjugate in the pollen mother cells; these chromosomes remain univalent and surround the gemini in the equatorial plates. The partners of the bivalent chromosomes first pass to the poles; the univalents, lagging a little, divide into 2 parts, which also pass to the poles. Daughter cells thus result with a number of chromosomes larger than the true haploid number. Probably by the homotypic division the pollen grains also get a number of chromosomes larger than 40.—*S. officinarum* often shows a high male sterility. To the author it seems not improbable that a relation exists between this sterility and the abnormal chromosome numbers and combinations in the pollen cells.—A preliminary research showed that 2 Dutch-Indian varieties of *Saccharum*, with the vernacular names of Loethers and Teboe hitam Rokan, differing in outer characteristics somewhat from *S. officinarum*, have other chromosome numbers than that of the latter species. Two varieties from British India, Chunnee, and Puckree, also differing from *S. officinarum* have ≈ 46 haploid chromosomes.—In species hybrids of other genera which have been investigated up to the present the number of chromosomes proved generally to be the total of the haploid numbers of the parents.—Highly fertile hybrids of *S. officinarum* \times *S. spontaneum* are easily obtained. Male sterility is rarely found, female sterility never. The author found that the somatic chromosome number of several of these hybrids was 136, the total of the diploid chromosome number of *S. officinarum* and the haploid number of *S. spontaneum*. Normal reduction division occurs, the haploid number being 68. The author thinks it probable that the normal reduction division may be the reason of the fertility of these hybrids. From morphological studies carried on at the same experiment station the conclusion had already been reached that the wild Kassoer cane was a hybrid of *S. spontaneum* and *S. officinarum*. The haploid chromosome number of Kassoer proved to be 68, in full accord with the number found in artificial crossings between these species.—In the megaspore

mother-cells of *S. officinarum* a normal reduction division was seen, from which the author concludes that a longitudinal splitting of the *S. officinarum* chromosomes in the egg cell during fecundation may be responsible for the increase in the number of chromosomes of the hybrid plants. In this case heterotriploid hybrids could be spoken of.—The volumes of the nuclei of the pollen mother-cells of *S. officinarum*, *S. spontaneum*, and *S. officinarum* × *S. spontaneum* are in accordance with the chromosome numbers.—*J. Kuyper*.

407. BUCHHOLZ, JOHN T., and A. F. BLAKESLEE. **Studies of the pollen tubes and abortive ovules of the Globe mutant of *Datura*.** *Science* 55: 597-599. 1922.—In *Datura* the $(2n + 1)$ Globe mutant complex is transmitted to less than 3 per cent of the offspring by the pollen, although half the pollen receives the extra chromosome. Similar segregation is indicated for the ovules. One-fourth the offspring of Globe × normal are Globes, but abortive ovules account for the missing Globes and make a 1:1 ratio. Thus there is greater mortality of Globe zygotes. Counts of abortive ovules in crosses made with Globes and normals suggest that 4-10 per cent of $(n + 1)$ pollen tubes enter the ovary. The authors' technique in counting and measuring pollen tubes in the styles is described. Distributions of pollen tubes in normals and Globes are shown as unimodal and bimodal curves respectively. In the Globes there is a faster- and a slower-growing group of pollen tubes, the latter probably the $(n + 1)$ group. There seems to be a selection between male gametophytes, this and other processes of developmental selection tending to cause the $(2n + 1)$ mutant to disappear.—*J. Lincoln Cartledge*.

408. DAHLGREN, K. V. OSSIAN. **Selbststerilität innerhalb Klonen von *Lysimachia Nummularia*.** [Self-sterility within clones of *Lysimachia Nummularia*.] [Abstract.] *Hereditas* 3: 200-210. 1922.—Several writers have asserted that *Lysimachia Nummularia* never, or extremely rarely, produces capsules. By pollination between individuals from different parts of northern and central Europe, it is now demonstrated, however, that fruits can sometimes be produced without difficulty. That this occurs so seldom in nature is due to self-sterility, and to the fact that all plants at a locality generally are members of the same clone. [See also Bot. Absts. 9, Entry 225.]-*K. V. Ossian Dahlgren*.

409. ELORDUY, SAMUEL TORRES. **El mejoramiento del maíz.** [Improvement of corn.] *Rev. Agric. [Mexico]* 6: 673-676. 6 fig. 1922.—Methods applicable in improving the corn crop of Mexico are popularly discussed.—*John A Stevenson*.

410. EULER, H. V., und INGVAR LAURIN. **Zur Kenntnis der Hefe *Saccharomyces Thermantitonum*.** [The yeast *Saccharomyces Thermantitonum*.] *Biochem. Zeitschr.* 102: 258-267. 1920.—The rate of growth, fermenting and inverting ability of a strain of *Saccharomyces Thermantitonum* grown in Berlin for 15 years on beer wort at 16°C. were determined. As the upper temperature limit for growth and the optimal temperature for fermentation are lower than in the original strain accustomed to high temperatures, it is concluded that adaptation to the new environment has occurred.—*H. D. Hooker, Jr.*

411. HAGEDOORN, A. L., und A. C. [HAGEDOORN]. **Species crosses in rats.** *Zeitschr. Indukt. Abstamm. u. Vererb.* 29: 97-121. 1922.—Descriptions of *Mus alexandrinum*, *M. rattus*, *M. tectorum*, and of house rats and tree rats of Java are presented, with notes on offspring resulting from certain crosses involving these forms. The characters considered in this series of matings are: light and dark belly color; black, agouti, yellow, silver, and chocolate coat color; white tail tip; and waltzing gait. Other characters, which occurred among field rats of Java and Sumatra, are discussed, namely, cream with black eyes, pale agouti and roan coat colors, and albinism. It is the authors' contention that new types arise by recombination of recessive determiners, as *aabb* from across between *AAbb* and *aaBB*, rather than by mutation.—*H. W. Feldman*.

412. HARDIN, W. L. **Outline of work in interest of avocado industry.** *California Citrogr.* 7: 204, 314-315. 1922.—A popular discussion of the need for systematic breeding of the

avocado and of the characteristics to be considered. The author especially stresses the variability of the avocado in protein content and its potential value as a source of protein. "Bud-selection" work is favored. One case of probably genetic somatic variation has been reported; a tree of the Ganter variety regularly produces black fruit on one branch.—Howard B. Frost.

413. HOOPER, J. J. **Studies of dairy cattle.** Kentucky Agric. Exp. Sta. Res. Bull. 234. 91-161. 1921.—(1) Inheritance of color markings in Jersey cattle. Sixty-six per cent of Jersey cattle are solid in color and have black tongues and switches, 12 per cent are broken in color with white tongues and switches, and 22 per cent have various combinations of color of the 3 units. Solid body color is dominant over broken, black tongue over white, and black switch over white. Apparently gray color is dominant to all other coat colors of Jersey cattle. (2) Influence of oestrus or heat on the production of milk and butter fat. J. J. HOOPER and P. E. BACON. No very decided fluctuation occurs during the period of heat. (3) Influence of age and pregnancy on the production of milk and butter fat in Jersey cows. Cows carrying a calf were found to produce slightly less milk. Young cows produce less milk and butter fat than mature cows. (4) The escutcheon in relation to production of milk and butter fat. An inspection of 1117 dairy cows shows that the selvedge type of escutcheon predominates among Jerseys while the Flandrine type is most common with Holsteins, Guernseys, Ayrshires, and Kerrys. No correlation was found between escutcheon type and milk and butter fat production. (5) The body secretions in relation to production of milk and butter fat. No correlation was found between the amount and color of body secretions found on the escutcheon, in the ears, and between the udder and thighs of dairy cattle, and milk and butter-fat production.—W. D. Valleau.

414. JEFFREY, E. C., A. E. LONGLEY, and C. W. T. PENLAND. **Polyploidy, polyspory and hybridism in the angiosperms.** Science 55: 517-518. 1922.—From investigation of known hybrids or species belonging to groups in which a great deal of natural hybridism is suspected, the conclusion has been reached that polyploidy (multiplication of the normal gametophytic number of chromosomes by 3, 4, etc.) is a common result of incompatible species crosses. In polyspory, which frequently accompanies polyploidy, the spore mother-cell, on account of irregular distribution of chromosomes at the 1st division, gives rise to more than 2 daughter nuclei,—generally 2 larger nuclei and as many as 4 smaller ones. After the 2nd division, 4 usually normal pollen grains and several small abortive grains result. Emphasis is placed upon abortive pollen which along with gigantism, mutability, polyploidy, and polyspory is offered as a morphological criterion of genetic impurity or heterozygosity in plants. A fuller publication is promised.—A. F. Blakeslee.

415. MAYER GMELIN, H. **Over Entbastaarden.** [On graft hybrids.] Culture 34: 205-216. 6 fig. 1922.—Graft hybrids were obtained of *Solanum Lycopersicum* with *S. nigrum* and with *S. Dulcamara*. No success was gained by reciprocally grafting *S. tuberosum* with *Physalis Francheti*, *Solanum Melongena*, *S. Lycopersicum*, *S. nigrum*, *Nicotiana glauca*, *Atropa Belladonna*, and *Datura Stramonium*. Periclinal and sectorial chimeras were obtained, the latter in the largest quantities. Indirectly, periclinal chimeras may be produced by sectorial chimeras. A suggestion is made of grafting more than 2 individuals, though the results may be smaller. If in the periclinal chimera the epidermis is produced by 1 component, the roots formed on cuttings will belong to the other component, since roots usually originate endogenously.—J. C. Th. Uphof.

416. RAWES, A. N. **Pollination in orchards (V).** Jour. Roy. Hort. Soc. 47: 8-14. 1922.—This paper reports work with apple varieties grown in plots in a glass house and is a continuation of work previously reported. Fifty varieties have been experimented with of which 8 are classed as self-fertile, 39 partly self-sterile, and 3 entirely self-sterile. Self-fertile varieties set fruit more freely when pollinated with pollen from other varieties. No instances of cross sterility have been discovered in apple varieties. The blooming periods of 10 varieties are

shown, and sufficient differences between early and late blooming varieties to interfere with cross pollination were found.—*J. K. Shaw.*

417. SHAMEL, A. D. Florida undertakes systematic citrus bud-selection work. California Citrogr. 7: 102, 127. 3 fig. 1922.—The Florida Agricultural Experiment Station has established a branch station primarily for work on "bud selection" and "stock selection" in citrus fruits, in cooperation with the U. S. Department of Agriculture. The author reports that the Alabama plantings of the Owari variety of "Satsuma orange" include "twelve or fifteen distinct strains."—*Howard B. Frost.*

418. SHAMEL, A. D. Relation of apple bud selection to citrus-fruit improvement. [Includes rev. of: DAVIS, M. B. The possibility of the transmission by asexual propagation of the high yielding ability of individual apple trees. Sci. Agric. 2: 120-124. 1921.] California Citrogr. 7: 112-113. 1922.—The reviewer states that he has found "much larger gains from propagation from superior parent citrus trees than those reported in the apple paper," and attributes this difference to selection from a larger number of trees in the citrus work. Citrus shows very distinct bud-variation strains within the commercial varieties.—*Howard B. Frost.*

419. SPRENGER, CARL. Iris-Züchtung und Iris-Verwendung. [Iris breeding and Iris improvement.] Gartenwelt 26: 270-271. 1922.—A general consideration of breeding and raising Iris as conducted by the author on the island of Corfu is presented. The following Iris hybrids are described: *Iris Jokaste* (*I. atropurpurea* × *I. susiana*), *I. Antigone* (*I. atropurpurea* × *I. Bismarckiana*), *I. Hippodamia* (*I. atropurpurea* × *I. susiana*), *I. Aerope* (*I. atropurpurea* × *I. susiana*), *I. Klytemnestra* (*I. atropurpurea* × *I. Saarii lurida*), *I. Iphigenia* (*I. atropurpurea* × *I. Saarii lurida*), *I. Electra* (*I. Saarii* × *I. susiana*), *I. Juno* (*I. Saarii lurida* × *I. iberica*), *I. Minerva* (*I. Saarii* × *I. iberica*), *I. Ceres* (*I. Saarii* × *I. Madonna?*), and *I. Latana* (*I. Saarii* × *I. iberica*).—*J. C. Th. Uphof.*

420. STOMPS, THEO. J. De Stoffelijke basis der erfelijkheid bij planten en dieren. [The material basis of heredity in plants and animals.] 270 p., 24 fig. Haarlem, 1922.—The writer gives a popular review of our present knowledge of the nucleus in relation to the phenomena of heredity. He considers mitosis as a kind of osmotic process. Size and difference in appearance between chromosomes of the same nucleus is most simply explained by supposing that the chromosomes are entirely independent organs with distinct external properties. An abnormal number of chromosomes is considered the cause of cancer.—*J. C. Th. Uphof.*

421. TOENNIEN, E. Über die Vererbung der Alkaptonurie des Menschen. [On the inheritance of alkaptonuria in human beings.] Zeitschr. Indukt. Abstamm.- u. Vererb. 29: 26-30. 1922.—Alkaptonuria is a condition in man in which the amino acids phenylalanin and tyrosin are not completely destroyed, causing arthritis and deposition of pigment in the cartilages. They are also found in the urine, causing characteristic coloring and deposits. A review of the cases of alkaptonuria already reported showing inheritance of the disease is made and charts are given. Summary of these data shows that the number of unaffected individuals in relation to those affected is as 3:1. These cases are small in point of number. This condition is not restricted to one sex and can be transmitted by either parent. No cases in which both parents are affected are reported. In 1 case quoted from Umber, 1 affected male, with no affected sibs, mated in an out blood to a non-affected female, produced 4 affected and 4 non-affected offspring. This the author considers a *RR* × *DR* mating because of the proportions. His conclusion is that alkaptonuria rests upon a recessive character and is not in the X chromosome as it is not sex-linked. This agrees with the physiological knowledge that the condition exists because of the absence of a ferment.—*A. H. Estabrook.*

422. VALLEAU, W. D., and E. J. KINNEY. Strains of standup White Burley tobacco resistant to root-rot. Kentucky Agric. Exp. Sta. Circ. 28. 16 p., 6 fig. 1922.—Tobacco root-rot caused by *Thielavia basicola* is the most serious disease of tobacco in the Burley section of

Kentucky. A discussion of the nature of root-rot, its effect on cultural practices and methods of control are considered. Growing of resistant varieties is thought to be the best method of control. The so-called Burley variety of tobacco is shown to be made up of a large number of distinct strains which breed fairly true although the progeny of some plants show distinct segregation. Selections of "standup" types of Burley have been made which appear to be very resistant to root-rot and of the desired "standup" type and of high quality. These are being tested commercially. Selection is being continued.—*W. D. Valleau.*

423. Y., G. U. Statistical method. [Rev. of: JONES, D. C. A first course in statistics. ix + 286 p. G. Bell and Sons: London, 1921.] *Nature* 109: 473-474. 1922.

HORTICULTURE

J. H. GOURLEY, *Editor*

(See also in this issue Entries 58, 134, 173, 174, 210, 285, 348, 373, 402, 404, 412, 416, 419, 672, 689, 690, 691, 692, 760, 831, 832, 888, 918)

FRUITS AND GENERAL HORTICULTURE

424. ANONYMOUS. Raspberries tried at Wisley. *Jour. Roy. Hort. Soc.* 47: 43-49. 1922.—Stocks representing 29 summer-fruited and 14 autumn-fruited varieties were tested and awards made by the Fruit and Vegetable Committee. Keys to the varieties and brief descriptions are given.—*J. K. Shaw.*

425. ANONYMOUS. Strawberries tried at Wisley 1920-21. *Jour. Roy. Hort. Soc.* 47: 50-55. 1922.—One hundred stocks representing 65 varieties of strawberries were tried and awards made. Owing to abnormal conditions no classification was attempted, but a table showing varietal characteristics and descriptions and notes of the several varieties are given.—*J. K. Shaw.*

426. ANONYMOUS. The Barham Court peaches. *Gard. Chron.* 70: 234. 1921.—These peaches were grown at Maidstone and exhibited at all important English exhibits a generation ago by Mr. Woodward, but now are rarely seen. The crop this season yielded about 17,000 fruits, the majority weighing 10-12 ounces. Mr. Woodward believes in young, vigorous trees and is constantly replanting during October and early November, using an abundance of wood ashes and top dressing. Duke of York is favored for early crops, and Hale's Early followed by Peregrin, Sea Eagle, and Nectarine Peach for late crops.—*P. L. Ricker.*

427. ARNOLD, W. S. The lemon. *Agric. Gaz. New South Wales* 33: 437-441. 1922.—In these practical cultural instructions particularly for the Kurrajong region, it is recommended that trees be fertilized by "soiling" (application of bush-land dirt) rather than by commercial fertilizers. It is suggested that the Australian native Kumquat, *Eremocitrus glauca*, be used as stock for grafting.—*L. R. Waldron.*

428. AUCHTER, E. C. Pruning and nitrogen studies in a devitalized peach orchard. *Proc. Amer. Soc. Hort. Sci.* 18: 178-193. 1921 [1922].—Devitalized peach trees 10 years old can be profitably rejuvenated by proper methods of soil management, spraying, worming, fertilizing, and pruning. Although good methods of soil management, worming, spraying, and applications of nitrate of soda have improved the general health of these trees, best results were not attained without some pruning. A moderately heavy pruning (cutting back into 3- or 4-year-old wood) gave best results. A moderately heavy pruning lowered the head of the tree noticeably, and in 2 years a new top was formed and vigorous growth stimulated through the lower parts of the tree. Trees in this condition should produce maximum crops for 6 or 8 years if properly managed. Although the partially pruned trees were stimulated so that

certain of the limbs will probably bear a fair crop, the growth on the dehorned limbs was so unsatisfactory that the gradual rebuilding of the tree was not attained. Provided each tree had enough main limbs to start with, so that a stub or two could be sacrificed without seriously impairing the shape, this method would, no doubt, be better than lightly pruning the tree and it might possibly equal the heavily pruned tree in yield over a 6- or 8-year average. The completely dehorned trees made a very dense, vigorous growth during both years, and were considerably dwarfed, and only a small number of fruit buds were formed on the long, over-vegetative shoots. This method was not so good as moderate pruning. With moderate or light pruning in the future, these trees will, no doubt, produce several profitable crops. Although light pruning produced a certain amount of stimulation in growth and fruit during the 2 years, it is very questionable whether the average production from trees so pruned will be enough in the next 6 years to justify use of the ground.—*W. E. Whitehouse.*

429. BALME, JUAN. **Un frutal japonesa de porvenir para la region subtropical de Mexico.** [A promising Japanese fruit for the subtropical region of Mexico.] *Rev. Agric. [Mexico]* 6: 516. 1921.—The author recommends the culture of the Japanese persimmon [*Diospyros Kaki*] in subtropical Mexico.—*John A. Stevenson.*

430. BARAKZAI, MAHOMED U. F. **Fruit culture as practised near Shikarpur, Sind.** Bombay Presidency Dept. Agric. Bull. 98. 14 p. 1920.—Shikarpur is on the western edge of the Sind Desert, India. The notes cover the propagation, irrigation, cultivation, flowering, yield, fruit preparation, pests, and local uses of the produce of the date (*Phoenix dactylifera*), pomegranate (*Punica Granatum*), crab apple (*Pyrus Malus*), guava (*Psidium Guajava*), and pharwan (*Grewia asiatica*).—*Robert L. Pendleton.*

431. BARTLETT, REG. G. **Better bananas. How to de-sucker to get them.** *Agric. Gaz. New South Wales* 33: 429-431. 2 fig. 1922.—Practical instructions are given.—*L. R. Waldron.*

432. BEATTIE, W. R. **The city home garden.** U. S. Dept. Agric. Farmers' Bull. 1044. 39 p., 16 fig. 1919.—This is a popular bulletin dealing with preparation of soil, tools, crops for the garden and their care. A table is appended giving the earliest and the latest safe dates for planting various vegetables in the open.—*C. G. Vinson.*

433. BECKETT, E. **Peaches and nectarines in the open.** *Gard. Chron.* 70: 139. Fig. 57. 1921.—The author gives notes on English cultural methods and conditions.—*P. L. Ricker.*

434. BIOLETTI, FREDERIC T. **Replacing missing vines.** *California Agric. Exp. Sta. Circ.* 249. 1922.—A loss of 27.8 pounds due to a missing muscat was accompanied by 5.6 pounds additional crop on the 2 neighboring vines, a compensation of about 20 per cent. For a missing Sultanina the compensation was 43 per cent. The filling of such gaps by the method of layering is recommended.—*A. R. C. Haas.*

435. BIOLETTI, FREDERIC T. **Vine pruning systems.** *California Agric. Exp. Sta. Circ.* 245. 4 p. 1922.—The systems best adapted to the conditions of grape growing in California are considered in 3 groups, head pruning, cane pruning, and cordon pruning; the advantages of each are explained.—*A. R. C. Haas.*

436. BLACKBURN, R. E. **Satsuma orange.** *Georgia State Coll. Agric. Circ.* 76. 4 p. 1918.—General directions are given for planting and handling this fruit in Georgia.—*T. H. McIlhatton.*

437. BRIERLEY, W. G. **Notes on the length of life of apple trees in Minnesota.** *Proc. Amer. Soc. Hort. Sci.* 18: 211-213. 1921 [1922].—The average apple tree in Minnesota commences bearing 6-8 years after planting, reaches its maximum production at about 20 years, then gradually fails. Apparently this is due mainly to climatic effects. Replies to a question-

naire sent to leading orchardists indicate that none of the common hardy varieties withstand Minnesota winters for 40 years. The length of life of these varieties is directly correlated with their hardiness.—*W. E. Whitehouse.*

438. BUNYARD, EDWARD A. **The winter study of fruit trees.** Jour. Roy. Hort. Soc. 47: 18-25. Pl. 3. 1922.—Since deciduous fruit trees are, for fully half a year, without leaves or flowers the woody parts have been examined for characters of assistance in identifying varieties. Moderately vigorous 1-year shoots from an exposed part of the tree are best. Characters considered are stoutness, degree of curving between the buds, internode length, color, hairiness, lenticels, and various peculiarities of both fruit- and leaf-buds. The form of adult trees is also of value. These characters in different varieties of apple, pear, cherry, and plum are discussed.—*J. K. Shaw.*

439. BURNS, W., and S. H. PRAYAG. **The book of the mango.** Bombay Dept. Agric. Bull. 103. 98 p., illus. 1920.—The authors' experiments on many phases of mango production and handling are described, as well as the results of other workers in India and in other mango-growing countries.—The treatment by chapters, is as follows: (1) The history of mangoes, their distribution through the world, suitable soils, climates, and altitudinal ranges; (2) propagation methods, including cuttings, layering, grafting, budding, and top-working; (3), planting, covering distances between trees, season, and care; (4) subsequent care, as manuring, irrigation, pruning, and inter-crops; (5) harvesting, packing, and marketing, including ripening, sale of crop on the trees, and export possibilities; (6) transport of trees, scions, and seeds, both for short and long distances and ocean shipments; (7) unsatisfactory plantations, discussing especially sterility and renovation of neglected groves; (8) time and methods of pollination; (9) pests and diseases,—insect, fungous, and others; (10) uses of the mango; (11) classification, proposing an artificial system based on fruit characters.—An appendix includes spray formulas and a descriptive list and illustrations of the fruits of 89 varieties of Bombay Presidency mangoes.—*Robert L. Pendleton.*

440. CHURCH, G. G., and E. M. CHASE. **Some changes in the composition of California avocados during growth.** U. S. Dept. Agric. Bull. 1073. 1922.—No satisfactory correlations were found between physical properties and maturity. The proportion of many of the constituents changes during development with marked increase in fat content. This takes place rapidly while the fruit is immature, much more slowly as it approaches maturity, accompanied by a decrease in sugar content. Fruits rich in fat contain at least 70 per cent on a water free basis at maturity. On storage of immature fruits there is an apparent increase in the proportion of fat and decrease in sugar content while mature fruits do not show this increase to the same extent. No standards of maturity are recommended.—*J. T. Buchholz.*

441. COLE, W. R. **Extension work in apple storage in Massachusetts.** Proc. Amer. Soc. Hort. Sci. 18: 130-135. 1921 [1922].—This report shows the present status of storage work among Massachusetts fruit growers. Common and air-cool storage on the farm, as practiced by a number of growers, means the utilization of existing cellars, or the construction of cellars for apple storage. The principles involved in this type of storage are discussed, and directions are given for utilizing old cellars.—*W. E. Whitehouse.*

442. CRANE, H. L. **Observations on the factors influencing the length of life of apple trees in West Virginia.** Proc. Amer. Soc. Hort. Sci. 18: 207-211. 1921 [1922].—The short life of apple trees in West Virginia is due primarily to shallow soils low in the elements of fertility; to the prevalence of diseases and insect pests; to climatic conditions, which seem to favor rapid development of trees and provide conditions in some cases almost ideal for diseases and insect pests; lastly to the varieties now grown, which come into bearing early and each year bear heavy crops, which exhausts the soil and weakens the trees.—*W. E. Whitehouse.*

443. CULLINAN, F. P. **Root development of the apple as affected by cultural practices.** Proc. Amer. Soc. Hort. Sci. 18: 197-203. 1921 [1922].—This paper contains observations on the

root development of Grimes apple trees after growing 8 seasons under sod, straw mulch, and tillage soil-management methods. The root systems of the trees under cultivation were quite symmetrical, spreading into all parts of the soil surrounding the trees. The main roots were found to a greater depth than those from the trees in the straw mulch or sod plots.—The trees under straw mulch had a shallow root system.—The trees in the sod made only a small growth but the root system as a whole did not come so near the surface as the roots under the straw mulch. A discussion of the factors influencing root development under these conditions is given.—*W. E. Whitehouse.*

444. DORSEY, M. J. Hardiness from the horticultural point of view. *Proc. Amer. Soc. Hort. Sci.* 18: 173-178. 1921 [1922].—This paper presents a study of the limitations of the variety as compared with the species from the hardiness standpoint. Investigation showed that with the species there are distinct regional types, individual variations, and that plants from the northern and southern part of the range of distribution may vary greatly in hardiness. The variety on the other hand may have some definite limitations as to plant characters or hardiness when compared with the species. Differences in the individual should be kept in mind in studying adaptation just as clearly as those in variety and species.—*W. E. Whitehouse.*

445. DURUZ, WILLIS P. Harvesting and handling apricots and plums for eastern shipment. *California Agric. Exp. Sta. Circ.* 239. 24 p. fig. 1-21. 1922.—Information and data obtained from successful growers of these fruits are given.—*A. R. C. Haas.*

446. DURUZ, WILLIS P. Harvesting and handling California peaches for eastern shipment. *California Agric. Exp. Sta. Circ.* 241. 21 p., fig 1-11. 1922.—The problems concerned with the harvesting and packing of California peaches, together with the costs involved, are considered in detail.—*A. R. C. Haas.*

447. DURUZ, WILLIS P. Harvesting and handling California pears for eastern shipment. *California Agric. Exp. Sta. Circ.* 240, 19 p. 1922.—Directions are given for harvesting and packing California pears for eastern shipment.—*A. R. C. Haas.*

448. FICHTER, G. Weiteres zur Unterlagen-Frage im Obstbau. [The question of stocks in pomology.] *Möllers Deutsch. Gärt. Zeitg.* 37: 173-175, 184-187. 7 fig. 1922.—In various types of stocks there is much difference in root development, which the author considers very important. Doucin I is considered the best, Doucin III is suitable for heavy growers such as Boskoop, Lebel, and Pontoise. Of Paradise stock the Yellow Metz is mentioned. Quince I as stock gives an upright growth to Pastor pear, Beurré Diel, and Blumenbach, whereas on Quince II they develop hanging branches. Under apple seedlings Höhenheimer, Frierscher Weinapfel, Rheinischer Bohnapfel are relatively constant and suitable as stock. Pears can be well grown on seedlings of Champagner Brat, Palmisch and Knaus.—*J. C. Th. Uphof.*

449. FREEMAN, W. G. The avocado in Trinidad and Tobago. *Bull. Dept. Agric. Trinidad and Tobago* 18: 113-124. 1919.—The writer describes the avocado (*Persea gratissima*) as to early history in the West Indies, common names, present distribution and cultivation. A table is given showing its comparative food value with that of other foods.—*Florence A. McCormick.*

450. GAJÓN, CARLOS. Como plantar los arboles frutales. [How to plant fruit trees.] *Rev. Agric. [Mexico]* 6: 391-395, 452-457. 30 fig. 1921.—A popular discussion is presented of varietal selection and propagation of the peach, fig, apple, nectarine, plum, pear, persimmon, and other fruits in Mexico.—*John A. Stevenson.*

451. GAJÓN, CARLOS. El mamey. [The mamey apple.] *Rev. Agric. [Mexico]* 6: 517-519. 4 fig. 1921.—The author discusses the planting, culture, pruning, and uses of *Lucuma mammosa*.—*John A. Stevenson.*

452. GARDNER, VICTOR RAY, FREDERICK C. BRADFORD, and H. D. HOOKER, JR. **Fundamentals of fruit production.** 686 p., 70 illus. McGraw-Hill Book Co.; New York, 1922.—This book is a text and reference work for college students but will also find ready use among progressive fruit growers. It "attempts to focus attention on the conditions which make the fruit plant profitable; practices are considered only as they affect these conditions, not as ends in themselves. . . . Plant physiology, soil chemistry, soil science and physics have been requisitioned freely and advisedly, in no case, however, without an indication of applicability to pomology." The following chapter heads indicate the subjects treated: The water requirements of fruit plants; the intake and utilization of water; orchard soil management methods and moisture conservation; soil moisture, its classification, movement, and influence on root distribution; the response of fruit plants to varying conditions of soil moisture and humidity; pathological conditions associated with excesses and deficiencies in moisture; plant nutrients and their absorption; individual elements; manufacture and utilization of carbohydrates; the initiation of the reproductive processes; surpluses and deficiencies; the application of nitrogen-carrying fertilizers; fertilizers, other than nitrogenous, in the orchard; growing season temperatures; winter killing and hardness; winter injury; winter injury to the roots; winter injury in relation to specific fruits; the occurrence of frosts; protection against frost; growing and fruiting habits; pruning, the amount or severity; pruning, the season; pruning with special reference to particular fruits; the structures and processes concerned in fruit setting; unfruitfulness associated with external factors; factors more directly concerned in the development of the fruit; fruit setting as an orchard problem; the reciprocal influences of stock and scion; the root systems of fruit plants; the geography of fruit growing; orchard locations and sites; orchard soils. A glossary is appended.—*J. H. Gourley.*

453. GIFFORD, F. R. **Converting the farm orchardist.** Proc. Amer. Soc. Hort. Sci. 18: 114-118. 1921 [1922].—This is a report of the peculiar problems encountered in extension work among orchardists in Wisconsin, where at least 75 per cent of the trees are in farm orchards, a large part of which are neglected. The method of carrying on extension work and the success attained by this method are discussed.—*W. E. Whitehouse.*

454. GIROLA, CARLOS D. **Cultivo de la yerba maté.** [Cultivation of "yerba maté."] Bol. Ministerio Agric. Nación [Argentina] 26: 129-142. 1 fig. 1921.—Paraguay tea or "yerba mate" (*Ilex paraguariensis* St. Hil.) has been much confused by some botanists with related species. Various varieties are recognized in Paraguay, the most important of which are *obtusifolia*, *acutifolia*, and *angustifolia*. Numerous other species of *Ilex* are used throughout South America for tea making. Brief notes covering botanical characteristics and the quality of the drink prepared from each are given.—*John A. Stevenson.*

455. GOKHALE, V. G. **Palm gul (sugar) manufacture in the Bombay Presidency (India).** Bombay Presidency Dept. Agric. Bull. 93. ii + 66 p., 11 pl. 1919.—The coconut palm (*Cocos nucifera*), date palm (*Phoenix sylvestris*), and palmira palm (*Bovassus flabeliformis*) are the more important palms of the Presidency.—In western India, toddy, a fermented drink is the only product of date palm juice. This bulletin is a study of the attempts made to introduce the Bengal method of making sugar from the fresh juice of date palm. Attention must be given to the use of lime, formalin, or the smoking out of the collecting pots to inhibit rapid fermentation; the boiling of the juice promptly after collecting; and the adoption of the more efficient Bengal methods of tapping, which will greatly decrease labor costs and increase the yield per tree. The output of fresh juice per tree per season (November-April) averages 17 imperial gallons, making 22 pounds of dark brown sugar. Unsuccessful experiments are reported on the use of a cheap acid to produce a lighter colored sugar. Illustrations and full details of tapping methods are given. There are numerous tables of analytical and sugar-making data.—There is not much probability that a sugar-making industry could use palms other than *Phoenix*. According to current prices palm-sugar making would be profitable only as a cottage or supplementary industry.—*Robert L. Pendleton.*

456. GOULD, H. P., and FRANK ANDREWS. **Peaches: production estimates and important commercial districts and varieties.** U. S. Dept. Agric. Bull. 806. 34 p., fig. 1-7. 1919.—The important commercial varieties and districts are given by states.—C. G. Vinson.

457. GOULD, H. P., and FRANK ANDREWS. **Pears: production estimates and important commercial districts and varieties.** U. S. Dept. Agric. Bull. 822. 16 p., fig. 1-3. 1920.—This publication gives the important commercial varieties and districts by states.—C. G. Vinson.

458. GOURLEY, J. H. **Text-book of pomology.** xv + 380 p., 8 pl., 40 fig. Macmillan Company: New York, 1922.—This volume is published in the Rural Text-Book Series, edited by L. H. Bailey. The purpose of the book "is to present the experimental and investigational bases of fruit-growing on the physiological side." The work represents an effort to provide a text suitable for college students who are already familiar with general orchard practice. Limited data in tabular form are offered as support for the conclusions throughout the work.—The following chapter headings indicate the scope of the book: Composition of fruits; buds of fruit-trees; differentiation of flower-buds; factors which influence fruit-bud formation; pruning; thinning of fruit; orchard soils; cultural methods in orchards; fertilizers and manures for the orchard; relation of climate to pomology; winter injury; pollination and the sterility problem; the origin and improvement of fruit; propagation and fruit-stocks; and storage of fruit.—J. H. Gourley.

459. HARRISON, G. H. **The most profitable varieties of peaches, cherries and apples for Maryland conditions.** Rept. Maryland Agric. Soc. 5: 295-302. 1920 [1921].

460. HILTS, R. W., and R. S. HOLLINGSHEAD. **A chemical study of the ripening and pickling of California olives.** U. S. Dept. Agric. Bull. 803. 24 p., pl. 1-5, fig. 1-9. 1920.—This bulletin gives the percentage of solids, oil, protein, and ash in the flesh and pits of fresh and ripe olives of various varieties. It was found that the percentage of oil in the fruit flesh is the best index to maturity for olives, both fresh and pickled.—Carl G. Vinson.

461. HOWARD, W. L. **The apricot in California.** California Agric. Exp. Sta. Circ. 238. 53 p., fig. 1-2. 1922.—A rather complete summary is given of the data regarding the cultivation, irrigation, pruning, thinning, spraying, disease and insect pests, frost protection, harvesting, and the costs involved in the growing of apricots in California.—A. R. C. Haas.

462. ITIÉ, GABRIEL. **Datos complementarios sobre el cultivo de la pifia.** [Additional data on pineapple culture.] Rev. Agric. [Mexico] 6: 645-649. 5 fig. 1922.—The author discusses the advantages and disadvantages of the different parts of the pineapple plant used for propagation, slips, crown slips, crowns, and suckers. Difficulties in pineapple cultivation experienced in Porto Rico, Hawaii, and Florida are reviewed.—John A. Stevenson.

463. LESLIE, W. R. **The Russian apple in America.** Proc. Amer. Soc. Hort. Sci. 18: 257-263. 1921 [1922].—This paper presents a history of the Russian apple in America, including introduction, present status, and influence on American horticulture.—W. E. Whitehouse.

464. LONGO, BIAGIO. **Su la vite selvatica della Maremma.** [On the wild vine of Maremma.] Atti R. Accad. Lincei Roma Rendiconti Cl. Sci. Fis. Mat. e Nat. 30²: 393-394. 1921.—Observations were made on the remarkable growth in Tuscan Maremma of the wild grape vine (*Vitis vinifera silvestris*). The possibilities of using this vine in agriculture, due to its apparent resistance to *Oidium*, *Peronospora*, and *Phylloxera*, are considered.—F. M. Blodgett.

465. LYNCH, W. D., C. C. McDONNELL, J. K. HAYWOOD, A. L. QUAINANCE, and M. B. WAITE. **Poisonous metals on sprayed fruits and vegetables.** U. S. Dept. Agric. Bull. 1027. 66 p. 1922.—When fruits and vegetables are sprayed in accordance with the schedules recommended by the Bureaus of Entomology and Plant Industry but little of the material used remains on the fruit or vegetable at harvest size.—Ira C. Swannan.

466. McHATTON, T. H., and N. D. PEACOCK. **Apple culture in Georgia.** Georgia State Coll. Agric. Bull. 239. 44 p., 22 fig. 1921.—The paper begins with a history of the apple in Georgia, and later gives a discussion of the best sites, locations, varieties, etc., for this fruit. It also contains a spray calendar and a discussion of common insects and diseases which attack the apple, ending with varietal adaptations and descriptions.—*T. H. McHatton.*

467. MACNAUGHTON, MALCOM. **The grape vine.** Gard. Chron. 71: 215, 233, 246, 262. 1922.—This is a lecture delivered to the Dundee Horticultural Association. Grapes are generally believed to have been introduced into England by the Romans, A. D. 10, and then trained to the tops of the highest trees; but little progress was made until they were grown under glass. The heating system, training, propagation, and care are described in detail.—*P. L. Ricker.*

468. MACOUN, W. T. **Observations on hardiness in the colder parts of Canada.** Proc. Amer. Soc. Hort. Sci. 18: 160-165. 1921 [1922].—This paper presents a brief history of the studies on hardiness in Canada, together with observations on the hardiness of stocks which are of great economic importance in Canada.—*W. E. Whitehouse.*

469. MEIER, F. C. **Wastage of fresh fruits and vegetables in transit and in storage.** Rept. Maryland Agric. Soc. 5: 310-318. 1920 [1921].—The several causes and remedial measures, with limited statistics on a few crops are given.—*A. Lee Schrader.*

470. MONTEALEGRE, MARIANO R. **La poda del cafeta.** [Pruning of coffee trees.] Bol. Camara Agric. Costa Rica 1: 113-128, 144-149. 1921.—A general discussion is presented of pruning in all its phases as related to coffee culture in Costa Rica.—*John A. Stevenson.*

471. OSKAMP, J. **The value of a more careful selection of plots and longer periods of observation in connection with pomological demonstrations.** Proc. Amer. Soc. Hort. Sci. 18: 113-114. 1921 [1922].

472. OVERHOLSER, E. L. **Cold storage as an aid to the marketing of plums.** California Agric. Exp. Sta. Bull. 344. 427-463. 1922.—The most desirable temperature for storage appears to be 32°F., there are, however, certain varieties of plums which keep well at 36°F. and which when properly picked and handled can be expected to hold up sufficiently well to be shipped by refrigerator boats through the Panama Canal to eastern coast markets. These varieties are: Kelsey, Wickson, Agen (French), Grand Duke, Satsuma, Yellow Egg, Pond, Climax, Tragedy, Robe de Sergeant, and Beauty; 4 other varieties (German, Imperial, Sultan, and Combination) may be suggested, although their keeping period at 36°F. is 7-10 days less. These last-named plums, however, will be marketable in eastern markets for only a relatively short period after removal from storage. Varieties of plums which appear to be unsuited for shipment east by boat, because of poor keeping qualities at 36°F., are Sugar, Columbia, Abundance, Botan, Burbank, Peach, Washington, and Clyman. The relative importance of the varieties of plums, as indicated by the amounts received upon the New York City markets during the season of 1920, is as follows: Kelsey, Pond (Gross, Hungarian), Wickson, Tragedy, Giant, Grand Duke, Diamond, Burbank, Climax, Beauty, American Blue, Clyman, Sugar, President, Gaviota, Santa Rosa, California Blue, Formosa, Purple Duane, German, Yellow Egg, and Apex. There is evidence that most of the shipping plums are frequently picked too green; 2-3 days longer upon the tree does not appreciably shorten their storage period and does result in larger size and better color and flavor.—*A. R. C. Haas.*

473. PARANJPE, H. P. **Cultivation of oranges and allied fruits in the Bombay Presidency (India).** Bombay Presidency Dept. Agric. Bull. 95. 23 p. 1919.—Horticultural practices in cultivating *Citrus* in western India are given.—The varieties grown belong to *C. decumana*, *C. Medica*, and *C. aurantium*. Of the last species there are commonly grown 3 loose-skinned and 1 tight-skinned varieties.—The particular climatic, soil, and cultural demands of the several varieties are given. Budding or otherwise propagating varieties on other than their own

stocks is desirable. Details of stocks and methods of propagation are described.—Root pruning, cultivation, withholding of irrigation water, manuring, and exposure of roots are some of the methods employed to control fruiting in order to produce a crop at the desired season. Suggestions are given as to possible reasons for failure. Diseases are numerous.—Analyses of orange garden soils and unsuitable irrigation water are appended.—*Robert L. Pendleton.*

474. PATVARDHAN, G. B. *Fruit culture in Palitana and Jamnagar (Kathiawar, India).* Bombay Presidency Dept. Agric. Bull. 101. 28 p., 3 pl. 1920.—In small plantings in Palitana Sweetwater, Muscatel, Black Hamburg, and Sultana vines are trained on wires or wooden supports. Detailed descriptions are given of the pruning system. The manuring practise is complicated, involving the annual removal of the soil from about the roots and replacing it with fresh soil mixed with lime, bone meal, and cotton seed cake. Wood ashes are used to ward off termite attacks. Irrigation, pruning, and spraying methods are fully described.—The citrus plantings are of Australian navels, Agra and Delhi oranges, sweet and sour limes, and Sicilian lemons. The cultural methods include green manuring with san (*Crotolaria juncea*), frequent irrigations, annual renewal of soil (mixed with fertilizers) about the roots, and careful pruning. Freshly slacked lime is spread under the trees to kill Mediterranean fruit flies, which are a very serious pest.—In a description of recent citrus plantings at Jamnagar, near the coast, good care is emphasized as essential. Effective windbreaks are necessary.—*Robert L. Pendleton.*

475. POPENOE, PAUL B. *Costa Rica, land of the banana.* Nation. Geog. Mag. 41: 201-220. 17 fig. 1922.—Notes are included on the growth and production of bananas and of coffee.—*W. M. Atwood.*

476. PRAYAG, S. H. *A preliminary note on the increase of grape yield.* Agric. Jour. India 17: 41-50. Pl. 4-5. 1922.—Experiments are described dealing with the most suitable method of training grapes in western India.—*A. Howard.*

477. PRETTYMAN, H. W., and H. S. VANDEVORT. *West Virginia demonstration community packing house, second report.* Proc. Amer. Soc. Hort. Sci. 18: 110-112. 1921 [1922].—This report of the second year's operation of a community packing house shows progress made, and the effect on development of packing houses in other communities. The packing house was in a position to determine for growers, by actual grading of a few small lots, whether their apples should be graded and barrelled or sent direct to the cannery.—*W. E. Whitehouse.*

478. PRIEGO, J. MANUEL. *Las variedades del olivo.* [Olive varieties.] Bol. Agric. Tech. Econ. [Spain] 14: 141-148. 1922.—The olive occurs widespread in Europe and Asia, growing under varying conditions, which has resulted in the origination of many varieties. The early Greeks and Egyptians recognized a number of varieties. Modern workers in France, Italy, and other countries have described a large number of distinct types. Some of the more important of these are briefly described.—*John A. Stevenson.*

479. RAWES, A. N., and S. FOX WILSON. *Pollination in orchards (VI).* Jour. Roy. Hort. Soc. 47: 15-17. 1922.—This paper deals with pollen-carrying agents. It was found that unlike hive bees wind is not an active agent in the distribution of fruit tree pollen. Several species of bumble bees were found to be active. House flies, midges, and small flies were also numerous.—*J. K. Shaw.*

480. REYNOLDS, PHILIP K. *Historia del platano.* [History of the banana.] Bol. Camara Agric. Costa Rica 1: 225-253. 1921.—An account is given of the banana industry as developed in Central America.—*John A. Stevenson.*

481. RIGOTARD, LAURENT. *La culture du noyer en France.* [The culture of walnuts in France.] Ann. Sci. Agron. Française et Etrangère 38: 1-9. 1921.—The following phases pertaining to the walnut are discussed: importance of export trade; decrease in production

in recent years; necessity of perfecting cultural practices; struggle against animal and vegetable parasites; scientific researches, theories, and practices; the rôle of a station in the study of the walnut.—A. B. Beaumont.

482. RUDOLF, W. **Experiments with common rock salt: (I) Effect on asparagus. (II) Eradication of weeds and cleaning of roadsides with salt. (III) After effects of salt.** *Soil Sci.* 12: 449-474. 1921.—Experiments with a top dressing of salt in addition to manure were made on 2- and 11-year asparagus plants. Common rock salt at the rate of 150, 300, and 500 pounds per acre was used. For the 2-year plants the salt increased the average total length of plants 21.1-38.7 per cent, the number of stems 2.9-26.8 per cent, and the average weight of stalks per plant the following year 5.3-17.1 per cent. Similar results were secured with the older plants. Experiments with salt for killing weeds and brush along roadsides showed that 8 tons per acre will kill all vegetation except asparagus. As a rule 5-6 tons are effective while 3-5 tons are not sufficient to kill deep-rooted plants. Salting should be done about mid-season just before a rain, and high, rank vegetation should be cut immediately before or after applications. The injurious action of 4-5 tons per acre are still evident the 2nd year while the effects of 3-3.5 tons are imperceptible. With 2-2.5 tons a fertilizing action seems to occur.—W. J. Robbins.

483. SET, G. B. **Some practical hints on the management of orchards in India.** *Agric. Jour. India* 16: 524-528. 1921.

484. SHAMEL, A. P., L. B. SCOTT, and C. S. POMEROY. **Frost protection in lemon orchards.** U. S. Depart. Agric. Bull. 821. 30 p., fig. 1-15. 1920.—Plats were selected containing 5-10 trees. A large percentage of fruit was saved in the winter of 1913 with adequate orchard heaters. Non-heated trees, injured by the freeze of 1913 and receiving good care, returned to normal production by January, 1914. The heating during the cold period of January, 1913, had practically no effect on the 2nd season's crop. The main effect of protecting trees during one season of low temperatures is in the saving of the crop for the current year. Lisbon trees bore a greater number of sound merchantable lemons after the freeze than Eureka, due to differences in habit of growth.—C. G. Vinson.

485. SHAMEL, A. D., L. B. SCOTT, C. S. POMEROY, and C. L. DYER. **Citrus fruit improvement, a study of bud variation in the Eureka lemon.** U. S. Dept. Agric. Bull. 813. 88 p., fig. 1-22. 1920.—Descriptions and performance records of 8 strains of the Eureka lemon are given.—C. G. Vinson.

486. SHAMEL, A. D., L. B. SCOTT, C. S. POMEROY, and L. S. DYER. **Citrus-fruit improvement, a study of bud variation in the Lisbon lemon.** U. S. Dept. Agric. Bull. 815. 70 p., fig. 1-14. 1920.—Performance records presented in this bulletin show that the Lisbon strain and the Open strain are the only ones of commercial importance. These strains of the Lisbon lemon are isolated through bud selection.—C. G. Vinson.

487. THOMAS, EDWARD E. **Studies on the irrigation of citrus groves.** California Agric. Exp. Sta. Bull. 341. 353-370. 1922.—Four points have been investigated in this work: (1) the amount of water in the soil at the upper and lower ends of long furrows; (2) the appearance and productiveness of trees growing at the upper and lower ends of long furrows; (3) the amount of available moisture in the soil when the water is applied at intervals of 30, 45, and 60 days; and (4) the effect of deep and shallow cultivation on the water-absorbing power of the soil.—(1) The results of this investigation indicate that irrigation furrows exceeding 250-300 feet in length are undesirable. When longer furrows are used the soil near the upper end inevitably receives an excess of water, becoming "water-logged." A portion of the soluble plant food will be leached and carried below the root zone by the water.—(2) Citrus trees growing on heavy soil may become stunted when excessively irrigated; the leaves turn more or less yellow and many of them fall prematurely. The yield of fruit is also greatly impaired and

in some instances the trees may become unprofitable. In many groves it would be advisable to install a greater number of distributing pipe lines in order to shorten the irrigation runs.—(3) In order to secure best results irrigation water should be applied at the time it is needed, as gauged by the moisture content of the soil; whenever this procedure is impracticable it should be applied at intervals best suited to the soil type, as determined by experience or definite experiments.—On heavy loam soils such as that under consideration, the soil moisture remained more uniform and the conditions for root development better, with a 60-day interval between irrigations, than with a 30-day interval.—(4) The water-absorbing power of heavy soil is influenced by the method of tillage. The soil should not be stirred while it is wet. Frequent shallow cultivation tends to pack the soil immediately below the cultivated area. The plow-sole thus formed retards the movement of water in the soil.—Good conditions for plant growth can be obtained by harrowing the soil lightly after it has become sufficiently dry near the surface to prevent puddling, then allowing it to remain undisturbed until it has dried out more deeply to permit deep and thorough cultivation.—A. R. C. Haas.

488. TROWBRIDGE, P. F. Report of the director, year ending June 30, 1921. North Dakota Agric. Exp. Sta. Bull. 159. 28-32, 2 fig. 1922.—Miscellaneous notes are given on varieties of vegetables, including onions, mangels, and potatoes; upon fruits, forest trees, and ornamentals.—L. R. Waldron.

489. WILLIAMS, R. O. Budding the avocado. Bull. Dept. Agric. Trinidad and Tobago 18: 125-128. 1919.—The writer brings forth additional evidence against the idea that the avocado is difficult to bud successfully. The method of budding, including the selection of buds and stocks, and the season for budding are given.—Florence A. McCormick.

490. WIMSHURST, C. R. Apple growing in Australasia and America: a comparison with English conditions. Jour. Ministry Agric. Great Britain 28: 1005-1010. 1922.

491. YOUNG, W. J. Preliminary report on the use of sodium silicate as a wound dressing. Proc. Amer. Soc. Hort. Sci. 18: 196-197. 1921 [1922].—The Muscadine grape if pruned after Jan. 1 bleeds excessively, and under certain conditions may bleed to death. The author found that wounds treated with sodium silicate solution remain dry and do not bleed.—W. E. Whitehouse.

FLORICULTURE AND ORNAMENTAL HORTICULTURE

492. ANONYMOUS. Dahlias at Wisley 1921. Jour. Roy. Hort. Soc. 47: 56-73. 1922.—This report of trials of 240 stocks gives the awards of a joint committee of the Royal Horticultural Society Floral Committee and the National Dahlia Society. The varieties are classified, and brief descriptive notes are given.—J. K. Shaw.

493. ANONYMOUS. Mid season peas at Wisley 1921. Jour. Roy. Hort. Soc. 47: 81-89. 1922.—Awards, descriptions, and notes of 153 pea stocks are given, and the varieties classified.—J. K. Shaw.

494. ANONYMOUS. Sweet peas at Wisley 1921. Jour. Roy. Hort. Soc. 47: 74-80. 1922.—Sweet peas (113 stocks) were judged under ordinary garden cultivation instead of as produced for exhibition. Awards, descriptions, and notes are given in a classified list of varieties.—J. K. Shaw.

495. BOECK, AUGUST. Eine Sortenauslese empfehlenswerter Phlox decussata-Züchtungen. [A select list of improved varieties of *Phlox decussata*.] Möllers Deutsch. Gärt. Zeitg. 37: 202-203. 1922.—The writer describes 33 varieties or hybrids of *Phlox decussata*, and arranged them according to color.—J. C. Th. Uphof.

496. BROTHERSTON, R. P. **The pentstemon.** Gard. Chron. 70: 208. 1921.—This flower is of comparatively modern cultivation, some of the more common species having been introduced into England about 1825. Notes on some of the species are given with dates of introduction.—P. L. Ricker.

497. BROTHERSTON, R. P. **The sweet williams.** Gard. Chron. 70: 136. 1921.—The sweet william, first mentioned by Turner in 1573, was in general cultivation in English gardens by 1629, but little progress was made in improving it until the 18th century. Some early hybrids are mentioned and brief cultural notes given.—P. L. Ricker.

498. DOHRN, P. H. **Deutsche Edelcanina.** [German improved Canina stock.] Möllers Deutsch. Gärt. Zeitg. 37: 175-176. 3 fig. 1922.—Deegens, Senffs, and Kokulinsky types of *Rosa canina* are described as stocks for rose varieties and hybrids.—J. C. Th. Uphof.

499. DYKES, W. R. **Crocus species.** Gard. Chron. 71: 126. 1922.—Some early species and varieties for cultivation are noted.—P. L. Ricker.

500. DYKES, W. R. **The classification of garden irises.** Jour. Roy. Hort. Soc. 47: 2-7. 1922.—This classification deals only with the bearded irises grown in gardens and is based on trials of varieties begun at Wisley in 1915. It was found impossible to base the classification on wild species, therefore color, height, and season are the characters used. An outline of color classification with typical examples is given. A complete list will follow.—J. K. Shaw.

501. EHRENTHAUT, E. **Camellien-Kultur.** [Camellia culture.] Möllers Deutsch. Gärt. Zeitg. 37: 159-160. 1922.—Camellia varieties are propagated by cuttings or by grafting on *C. Chandleri elegans* and *Campbell*. The latter species especially is used for varieties which are difficult to grow from cuttings or which do not produce well-developed buds. Cuttings taken in July or November-December must have 3-5 leaves. They are put in propagating beds containing sandy heather soil at a temperature of 20-22°C. At irregular soil temperatures the cuttings produce large callous but no roots. When rooted they are put into small pots containing heather and lawn soil. The 3rd year they are planted in larger pots. During winter they are kept close under the glass in a light greenhouse which is free from frost.—J. C. Th. Uphof.

502. ELWES, H. J. **The Darrah collection of cacti at Manchester.** Gard. Chron. 70: 198-199. 1921.—A very large collection of succulent cacti, assembled by the late Charles Darrah, was presented by his widow to the corporation of Manchester in 1903. A range of houses, built in Alexandra Park to contain the collections, was opened to the public in December, 1906. A catalog of the original bequest lists 1,350 species and contains many interesting notes.—P. L. Ricker.

503. GROVE, A. **Lilies in 1921.** Gard. Chron. 71: 228-229. 1922.—This is a general consideration of meteorological conditions in relation to disease and various species in cultivation.—P. L. Ricker.

504. HALL, DANIEL. **The florists' tulip.** Gard. Chron. 71: 128, 140. 1922.—This is a lecture delivered at a recent meeting of the London School Gardening Association.—P. L. Ricker.

505. HASTINGS, G. T. [Rev. of: TRELEASE, WILLIAM. **Plant materials of decorative gardening. The woody plants.** xliii + 177 p. Urbana, Illinois, 1921. \$1.00] Torrey 22: 88. 1922.—This 2nd edition presents 4 keys to the trees, shrubs, undershrubs, and woody climbers found commonly in cultivation in the eastern U. S. A.; 7 genera are described, and 1,150 species mentioned. A glossary is attached.—J. C. Nelson.

506. HEAL, JOHN. Blue flowering climbers for the greenhouse. Gard. Chron. 71: 305-306. 1922.—Notes on plants for runner use, temperature requirements, and best method of handling are given.—*P. L. Ricker.*

507. HEAL, JOHN. *Dracaena*. Gard. Chron. 71: 154. Pl. 78. 1922.—Notes on introduction, best species and varieties, and methods of cultivation are given.—*P. L. Ricker.*

508. HENRY, A. *Populus generosa*. Gard. Chron. 70: 232. 1921.—Two trees at Kew 7 years old from seed are 36½ feet high with a girth of 21½ inches breast high. This vigorous hybrid was first introduced at Kew in March 1912 from a cross made by dusting pollen of the west American balsam poplar (*P. trichocarpa*) on pistillate flowers of a black poplar (*P. angulata*). It is well worth cultivating both as an ornamental and possibly as a timber tree; it demands freedom from shade and has an extensive root system.—*P. L. Ricker.*

509. HURST, C. C., and MABEL S. G. BREEZE. Notes on the origin of the moss-rose. Jour. Roy. Hort. Soc. 47: 26-42. 1922.—The moss rose, *Rosa muscosa*, of Miller differs from the cabbage rose, *R. centifolia*, in its multiplicity of glandular organs. Reviews of the histories of the old cabbage rose and of the moss rose are given. The former has been freely cultivated in Europe for more than 2000 years. The moss rose is traced back to about 1696 to the south of France and is considered to have arisen from the cabbage rose by bud mutation on 3 different occasions. The White Provence or Rose Unique and Rose de Meaux have also given origin to moss forms by bud mutations. It is not known whether the "moss" character is due to a single Mendelian factor but the evidence is in favor of its being a simple dominant. A list of 104 papers is appended.—*J. K. Shaw.*

510. KACHE, PAUL. *Primula malacoides* und ihre Hochzucht für den Winterflor. [Primula malacoides and its breeding for winter-flowering.] Möllers Deutsch. Gärt. Zeitg. 37: 197-199. 1 fig. 1922.—Berlin, a type of this species observed in the trial grounds of the Horticultural College in Dahlem, had larger and more beautifully shaped flowers which were self fertilized, the offspring closely resembling the parent.—*J. C. Th. Uphof.*

511. KREBS, JOS. Kultur und Anzucht der Gloxinien. [Growing Gloxinias.] Gartenwelt 26: 339. 1922.—Seed of Gloxinias is sown January-February in fine muck or sandy leaf soil with a temperature of 25°C. The sown seed is not covered with soil. Seedlings transplanted 2-3 times and kept at 25-30°C. are large enough to be transplanted into 12-cm. pots and will flower late in July. The soil should be composed of leaf mould, muck sand, rotted manure, and some horn meal. In very hot weather plants should be sprayed with water and shaded. For each tuber only 2-3 of the best shoots are retained.—*J. C. Th. Uphof.*

512. MAGOR, E. J. P. *Rhododendrons*. Gard. Chron. 71: 42-43. 1922.—It is stated that lime and not peat is necessary for the growth of Rhododendrons and that the latter is often fatal to them. The best varieties for cultivation are discussed.—*P. L. Ricker.*

513. MULFORD, F. L. Street trees. U. S. Dept. Agric. Bull. 816. 58 p., fig. 1-37. 1920.—An outline map of U. S. A. shows the regions within which essentially similar conditions for tree growth exist. Descriptions of trees and palms suitable for planting in the various districts are given.—*C. G. Vinson.*

514. PATEMAN, T. Winter flowering carnations. Gard. Chron. 71: 141. Fig. 69. 1922.—Notes are given on some of the best varieties arranged according to color.—*P. L. Ricker.*

515. PRIEGO, J. MANUEL. La variedad en arboricultura. [The variety in arboriculture.] Bol. Agric. Tech. Econ. [Spain] 14: 39-45. 1922.—The author discusses the origin of varieties, their importance in arboriculture, the fixing of new varieties, and the characters used to distinguish them.—*John A. Stevenson.*

516. PROSCHOWSKY, A. ROBERTSON. Palms of the Riviera. Gard. Chron. 70: 184-185. 1921.—A note is presented on the species of *Cocos* now referred to the genus *Blutia*.—P. L. Ricker.

517. PROSCHOWSKY, A. ROBERTSON. Palms of the Riviera. Gard. Chron. 71: 153. Pl. 77. 1922.—Notes on *Arecastrum romanzoffianum* are given.—P. L. Ricker.

518. SMITH, THOMAS. Raising alpine plants from seed. Gard. Chron. 71: 156. 1922.—A list of 36 genera taken from an English seed catalogue is given, with detailed methods of propagation.—P. L. Ricker.

519. THATCHER, A. E. Chinese climbers at Aldenham. Gard. Chron. 71: 270, 305. Pl. 144, 167. 1922.—Notes are given on *Actinidia*, *Celastrus*, *Clematis*, *Holboellia*, *Coculus*, *Drayea*, *Lonicera*, *Rubus*, *Sargentodoxa*, *Schizandra*, *Sinofranchetia*, and *Vitis*.—P. L. Ricker.

520. THATCHER, A. E. Chinese shrubs at Aldenham. Gard. Chron. 71: 114-115, 123, 137, 179, 199. Fig. 56, 67, 92, 102, 111. 1922.—Notes are presented on plants principally introduced to English gardening as a result of the 3rd Chinese expedition of E. H. Wilson.—P. L. Ricker.

VEGETABLE CULTURE

521. ANONYMOUS. Experiments in the cultivation of tomatoes. Exp. and Research Sta. Nursery and Market Garden Industries Development Soc. Ltd., Turner's Hill, Cheshunt Herts, Ann. Rept. 7: 8-13. 1921.—Mulches, base manures, and top dressings are discussed, with figures to show the effects of each on yield of tomatoes (*Lycopersicum esculentum* Mill.). Proper aeration also increased the yields.—W. H. Tisdale.

522. ANONYMOUS. The manurial experiments. Exp. and Research Sta. Nursery and Market Garden Industries Development Soc. Ltd., Turner's Hill, Cheshunt, Herts, Ann. Rept. 7: 8-13. 1921.—For Tomatoes (*Lycopersicum esculentum*) various combinations of artificials with and without dung and with and without some of the principle constituents are reported. The best yields were obtained with complete artificials minus nitrogen and minus dung. With Cucumbers (*Cucumis sativus*) the best results were obtained with complete artificials minus nitrogen. Artificials without nitrogen and dung also gave good results.—W. H. Tisdale.

523. AYRES, W. E. Vegetables and truck for home use. Mississippi Agric. Exp. Sta. Bull. 210. 16 p., 9 fig. 1921.—Variety tests under Mississippi Delta conditions are reported for turnips, tomatoes, Irish potatoes, sweet potatoes, beets, bush beans, sweet corn, cucumbers, squash, watermelons, and cantaloupes. Results with different methods of training tomatoes and suggestions for growing spinach, collards, lettuce, cabbage, okra, pepper, radishes, lima beans, garden peas, onions, strawberries, and blackberries are also given.—J. Fred O'Kelly.

524. BOSE, S. R. Possibility of mushroom industry by cultivation. Agric. Jour. India 16: 643-647. 1921.

525. BROWN, H. D. Canning-factory tomatoes. Indiana (Purdue) Agric. Exp. Sta. Bull. 259. 20 p., 7 fig. and frontispiece. 1922.—Indiana is one of the 4 leading states in canning-tomato production. The yield of wheat following tomatoes is greater than the yield following wheat, corn, or even clover. Methods of growing the plants and transplanting are described. Yield data for different fertilizers are given; 500-1,000 pounds per acre of a 2-12-6 fertilizer is recommended. Acid phosphate increases the earliness of the crop.—Max W. Gardner.

526. DOMINGUEZ, IGNACIO. *La alcachofa*. [The globe artichoke.] Rev. Agric. [Mexico] 7: 73-76. 4 fig. 1922.—The author discusses the culture, harvesting, and uses of the globe artichoke under Mexican conditions.—*John A. Stevenson*.

527. ESCOBAR, ROMULO. *El esparrago*. [Asparagus.] Rev. Agric. [Mexico] 7: 15-19. 3 fig. 1922.—Popular.—*John A. Stevenson*.

528. FIROR, GEORGE H., and LOIS P. DOWDLE. *Pimento growing*. Georgia State Coll. Agric. Bull. 234. 16 p., 5 fig. 1921.—Pimento, a variety of pepper (*Capsicum annum* L.), is popular because of its mild flavor, thick meat, and smooth skin. Seed should be started in hot beds and plants set into a friable, fertile loam in rows 3 feet apart and 14-18 inches in the row. The latter part of the bulletin contains instructions for canning and cooking pimentos.—*T. H. McHatton*.

529. GAY, M. C. *Harvesting, storing and marketing sweet potatoes*. Georgia State Coll. Agric. Bull. 244. 12 p., 1 fig. 1921.—A general discussion is given of the proper methods of harvesting and handling commercially the sweet potato (*Ipomoea batatas* L.).—*T. H. McHatton*.

530. MÜLLERS, L. *Gemüsesamenbau*. [Vegetable seed growing.] Gartenwelt 26: 300-302. 12 fig. 1922.—Suggestions for growing seed of white and red cabbage and cauliflower are given.—*J. C. Th. Uphof*.

531. OROZCO, ENRIQUE. *El cultivo de hongos en la Sierra de Puebla*. [Mushroom cultivation in the Sierra Puebla.] Rev. Agric. [Mexico] 6: 326-331. 7 fig. 1921.—A popular article on mushroom growing, in which *Clavaria tlahuicole* is mentioned, but not described, as a new species.—*John A. Stevenson*.

532. SANDO, CHARLES E. *The process of ripening in the tomato, considered especially from the commercial standpoint*. U. S. Dept. Agric. Bull. 859. 38 p., pl. 1-4. 1920.—This publication gives analyses of tomatoes of several degrees of maturity and of tomatoes ripened artificially under various conditions of vegetation. Throughout the ripening period there was found an increase in moisture, acids, and sugars, and a decrease in solids, total nitrogen, starch, pentosans, crude fiber, and ash. Lack of ventilation during ripening increased the acid content approximately 138 per cent. The flavor of tomatoes ripened without ventilation was very inferior.—*C. G. Vinson*.

533. STUCKEY, H. P. *Further studies in fertilizing and storing sweet potatoes*. Georgia State Exp. Sta. Bull. 134. 11 p. 1919.—This bulletin reports work from 1914 to 1919, following the report of work from 1908 to 1913 in bulletin 107. Six plots were used in the fertilizer work (1) 24 tons of stable manure annually; (2) 2,100 pounds of 16 per cent acid phosphate; (3) 900 pounds of sulphate of potash; (4) 1,500 pounds of sodium nitrate; (5) 1,800 pounds of a complete fertilizer; (6) check. The soil was a Cecil clay loam. After 12 years the complete fertilizer plot led all others, with the stable manure plot next; but the yields obtained in excess of those of the check did not pay for the fertilizer. The nitrogeous plots yielded roots (*Ipomoea batatis*) of a lighter color and poorer flavor; the best quality products were obtained from the check and acid phosphate plots. The check plot produced the best keeping roots, and those from the grey land kept better than those from the red. In storage it was ascertained that potatoes lose an average of 16.6 per cent in weight from November to March; 3.73 per cent is the loss in water and the remainder is presumed to be due to the breaking down of carbohydrates and formation of CO₂.—*T. H. McHatton*.

534. WAGNER, F. *Der Hopfenbrau in Bayern*. [Hop culture in Bavaria.] Illustr. Landw. Zeitg. 42: 197-198. 1922.—A history and brief description of the hop industry of Bavaria is sketched.—*John W. Roberts*.

HORTICULTURAL PRODUCTS

535. GREGER, JUSTIN. Über Traubenholunder-Marmelade. [Elderberry marmalade.] Zeitschr. Untersuch. Nahrungs- u. Genussmittel 42: 383-384. 1921.—Products of *Sambucus nigra* and *S. racemosa* are compared.—*E. E. Stanford*.

536. KRUG, O., und G. F. FIESELDMANN. Die 1921-er Weinernte in der Pfalz. [Vintage of 1921 in the Palatinate.] Zeitschr. Untersuch. Nahrungs- u. Genussmittel 42: 384-389. 1921.

MORPHOLOGY, ANATOMY AND HISTOLOGY OF VASCULAR PLANTS

E. W. SINNOTT, *Editor*

(See also in this issue Entries 183, 197, 215, 227, 228, 246, 439, 542, 647, 673, 680, 761, 777, 828, 902, 914, 925)

537. DENHAM, HUMPHREY JOHN. The structure of the cotton hair and its botanical aspects. Jour. Textile Inst. 13: 99-112. 1 pl. 1922.—The structure of the cotton hair is described in detail as to general conformation; primary wall; secondary wall; central canal and contents; pits, spiral markings and convolutions, and various abnormalities. The hair is a typical plant hair except that unlike other epidermal cells it has pits in its wall. Various explanations are suggested for the spiral markings and striations, these evidently having some connection with the spiral path of the nucleus and cytoplasm. The function of the cotton hair is unknown but the author suggests that it may afford an outlet for the elimination of excess polysaccharide material at a time when the needs of the plant are chiefly protein for the developing seeds.—*E. W. Sinnott*.

538. VUILLEMIN, PAUL. L'inflorescence. [The inflorescence.] Bull. Soc. Sci. Nancy IV, 1: 57-67. 1921.—Popular explanation of forms of inflorescence in phanerogams, with tabular recapitulation, is presented.—*A. Chase*.

539. WERTH, E. Zur experimentellen Erzeugung eingeschlechtiger Maispflanzen und zur Frage: Wo entwickeln sich gemischte (androgyn) Blütenstände am Mais? [On the experimental production of unisexual maize plants and the question: Where are hermaphrodite inflorescences developed in maize?] Ber. Deutsch. Bot. Ges. 40: 69-77. Fig. 1-2. 1922.—Maize plants were grown in crowded conditions in 20-22 cm. pots. The resulting plants were divided into 11 groups based on the degree of development of pistillate and staminate inflorescences. The more starved showed an increased tendency to form pistillate inflorescences. The 1st of the 11 groups contained normal plants; the 11th, sterile stalks with deformed essential organs; and the other groups showed variations between these 2 extreme conditions. However, no plant with only pure staminate flowers was observed. The plants ranged from 2.5 to 75 cm. in height. Experimental mutilation failed to increase the number of suckers. The percentage of hermaphrodite inflorescences on both the main stalk and the suckers was changed by selection but much more in the case of the suckers. There seemed to be a relation between size of the sucker and kind of inflorescence. The suckers with terminal staminate inflorescence were almost as fully developed as the primary stalk. The presence of hermaphrodite terminal flowers reduced the length growth, as did the presence of pistillate terminal inflorescences. These findings do not accord with previous reports of Goebel in the fir. The terminal part of a plant receives more nourishment than the lower portion, hence in maize the terminal inflorescence is normally staminate and the less well nourished lateral inflorescence develops as pistillate.—*J. L. Collins*.

540. ZIMMERMANN, A. Zur physiologischen Anatomie der Cucurbitaceen. [On the physiological anatomy of the Cucurbitaceae.] Ber. Deutsch. Bot. Ges. 40: 2-8. 1922.—This paper is based on a comparative study of the anatomy of a large number of representatives

of the family occurring in German East Africa (Amani). It includes a large number of observations relative to stomata; trichomes; number, location, course, and character of vascular bundles; occurrence of sieve tubes outside the bundles; abnormalities in the secondary thickening of the stem; differences in sun and shade leaves; presence of cystoliths, and power of the cells of the ground tissue of the stem to accumulate methylene blue and eosin from solutions of these pigments.—*Richard Holman.*

MORPHOLOGY AND TAXONOMY OF ALGAE

E. N. TRANSEAU, *Editor*
L. H. TIFFANY, *Assistant Editor*

(See also in this issue Entries 243, 266, 776, 810, 833, 835)

541. BORGE, O. Die Algenflora des Tåkernsees. [The algal flora of the Takern Lake.] Sjön Tåkerns Fauna och Flora Vol. 4. K. Svenska Vetenskapsakademien. 48 p. 40 fig. 1921.—A systematic account together with descriptions and notes on the occurrence of some 300 species and varieties of algae is given. About a third belong to the Desmidiaceae. The following are described as new: *Anabaena subcylindrica*, *Cosmarium Printzii*, *C. subturpinii*, *C. praecisum*, *C. geometricum* West var. *suecicum*, *Staurastrum tetracerum* (Kütz.) Ralfs. var. *tortum* (Teiling) n. comb., *S. papillosum* Kirchn. var. *contiguum*.—*L. H. Tiffany.*

542. CHEMIN, E. Sur le parasitisme de *Sphacelaria bipinnata* Sauvageau. [On parasitism of *Sphacelaria bipinnata*.] Compt. Rend. Acad. Sci. Paris 174: 244-247. Figs. 1-2. 1922.—It is found that *S. bipinnata* cannot be considered a true parasite, as it requires only support and receives no nourishment from its host. The tissues of *Halidrys siliquosa* is figured and described, both before and after the attached plants of *Sphacelaria* have been removed. Complete regeneration of tissue has in the meantime been accomplished.—*C. H. Farr.*

543. CHURCH, A. H. The somatic organization of the Phaeophyceae; an introduction to the theory of the plant-soma. Bot. Mem. [Oxford] 10. 110 p. 1920.—The Phaeophyceae, though relatively few in number of genera (130) and species (1,000), as at present recorded, show a range of somatic and reproductive specialization beyond that of any other empirical plant series, and are of outstanding interest in that they illustrate the evolution of massive parenchymatous growth-forms as the inevitable response of autotrophic life to the physical factors of the sea. The working hypothesis put forward is that the soma of land-vegetation has not been evolved independently, in response to the conditions of sub-aerial environment, but that its fundamental features have been inherited and adapted from a former submerged phase; and that the evolutionary progress of the plant body can be traced in the evolution of the plant soma within this dominant group of marine vegetation. An attempt is thus made to account phyletically for the morphological distinctions in the land plant. The Benthic Phase of plant-life falls into 3 main epochs: (1) The rise of the filamentous soma in deeper water from the first sessile encysted autotrophic flagellate; (2) the rise of algal growth nearer the surface in shallow and well-illuminated water, with shock of wave-action, culminating in massive growth forms of submarine forest vegetation; (3) elaboration of reef-pool conditions as the first land-masses break above the surface. The plant soma of the land is but the seaweed soma adapted and enlarged for its new conditions; the general features of habit still traced in the forest tree were laid down, once for all, in the first benthic filament of the rising sea-bottom.—*Edith Philip Smith.*

544. DICK, J. Beiträge zur Kenntnis der Desmidiaceen-Flora von Südbayern. [Contributions to our knowledge of the desmid flora of South Bavaria.] Krypt. Forsch. Bayer. Bot. Ges. München 4: 230-262. Pl. 11-17. 1919.—The report here given is based on explorations made during the years 1912-1916. The region studied is situated south of Munich, and the

author gives a detailed account of the various localities visited. He lists the desmids, 254 in number, which he has detected and represents many of them on the accompanying plates. Under each species cell-measurements and full data regarding localities are given, and these are often supplemented by descriptive or critical remarks. Although no novelties are formally proposed under new names, a number of aberrant forms are mentioned and their distinctive features indicated.—A. W. Evans.

545. KAISER, PAUL E. *Beiträge zur Kenntnis der Algenflora von Traunstein und dem Chiemgau.* [Contributions to the algal flora of Traunstein and Chiem Lake district.] Krypt. Forsch. Bayer. Bot. Ges. München 3: 130-148. 20 fig. 1918.—The present paper represents the 4th of a series devoted to the algal flora of southeastern Bavaria, the earlier numbers having appeared prior to 1918. The species, varieties, and forms enumerated number 131 and are classified as follows: Cyanophyceae (14), Flagellatae and Dinoflagellatae (5), Zygomyceteae (37), Conjugatae (60), and Chlorophyceae (16). The only new species proposed is *Spirulina vaginata*, but 3 new varieties or forms are described among the diatoms (Zygomyceteae). In addition to these, 38 algae are reported for the first time from Bavaria. Full data regarding stations are given throughout, and many of the forms are accompanied by critical or descriptive notes. The majority of the figures illustrate desmids.—A. W. Evans.

546. KAISER, PAUL E. *Desmidiaceen des Berchtesgadener Landes.* [Desmids of the Berchtesgaden region.] Krypt. Forsch. Bayer. Bot. Ges. München 4: 216-230. 34 fig. 1919.—The present report on the desmids of southeastern Bavaria is based almost entirely on collections made by Von Schoenau. The species, varieties, and forms enumerated number 154 and represent 17 genera; of these *Cosmarium* includes 65 species (and varieties), *Staurostrum* 26, *Euastrum* 14, *Closterium* 13, and the others less than 10 each. Each species is accompanied by cell-measurements, data regarding stations, references to published figures, and (in many cases) descriptive or critical notes. No new species are described but 4 new varieties and forms are proposed. The figures illustrate specimens of unusual interest.—A. W. Evans.

547. MAYER, ANTON. *Bacillariales der Umgegend von Ortenburg (Niederbayern).* [Diatoms from the vicinity of Ortenburg (Lower Bavaria).] Krypt. Forsch. Bayer. Bot. Ges. München 3: 122-148. Pl. 3-4. 1918.—The author gives a report based on his own collections of April, 1917. The species detected number 102 and represent 27 genera. *Nitzschia palea* var. *romana* Grunow is raised to specific rank under the name *N. romana* (Grunow) A. Mayer, and 8 other species or varieties are recorded for the first time from Bavaria. Many of the species are accompanied by descriptive or critical remarks, and forms of unusual interest are figured.—A. W. Evans.

548. MAYER, ANTON. *Bacillariales von Reichenhall und Umgebung.* [Diatoms of Reichenhall and vicinity.] Krypt. Forsch. Bayer. Bot. Ges. München 4: 191-215. Pl. 5-10. 1919.—The present report is based on a series of collections made by Von Schoenau. The species listed number 201 and represent 36 genera. Many of the species are accompanied by descriptive or critical remarks, and most of the more interesting specimens are figured. In certain cases distinct varieties or forms are enumerated. Several varieties and the following species are proposed as new: *Achnanthes conspicua*, *Cocconeis thumensis*, *Fragilaria gracilima*, *Navicula dimidiata*, *N. graciloides*, *N. involuta*, *N. lacta*, *Neidium tenellum*, *Surirella thumensis*, and *Synedra delicatula*.—A. W. Evans.

549. MAYER, ANTON. *Die bayerischen Eunotien.* [The Bavarian species of Eunotia.] Krypt. Forsch. Bayer. Bot. Ges. München 3: 95-121. Pl. 1-2, 3 fig. 1918.—The diatom genus *Eunotia*, according to the present report, is represented in Bavaria by 23 species, under several of which distinct varieties or forms are recognized. For the whole of Germany only 27 species have been definitely recorded. After an account of the generic characters and a key for the determination of the species, the latter are fully and critically described, with citations of the literature and definite data regarding Bavarian stations. The various species, varieties, and forms are figured.—A. W. Evans.

550. MERRIMAN, MABEL L. A new species of *Spirogyra* with unusual arrangement of the chromatophores. Amer. Jour. Bot. 9: 283-284. 3 fig. 1922.—A new species, *S. rectispira*, is described from New York City. It is closely related to *S. crassa*, from which it differs in its smaller zygospores and in the parallel arrangement of the chromatophores in vegetative cells of conjugating threads.—E. W. Sinnott.

551. PRINTZ, HENRIK. Subaerial algae from South Africa. Det Kgl. Norske Videnskabers Selskabs Skrifter 1921: 1-41. 14 pl. 1921.—An examination of 403 samples of subaerial algae collected in the environs of Durban and of Saldanha Bay, Africa, revealed 22 species. The following are described as new: *Protococcus consociatus*, *P. verrucosus*, *Chlorococcum vitiosum*, *Phaseolaria obliqua* nov. gen. et sp., *Myrmecia globosa* nov. gen. et sp., *Acanthococcus granulatus* Reinsch var. *aerophilus*, *Pleurastrum constipatum*, *Physolinum monile* (De Wildem.) nov. gen. et comb., *Trentepohlia lagenifera* (Hildebrandt) Wille var. *africana*, *Atractella affixa* nov. gen. et sp., *Myxosarcina concinna* nov. gen. et sp. The last two are Myxophyceae, the others Chlorophyceae.—L. H. Tiffany.

552. PUYMALY, A. DE. Reproduction des *Vaucheria* par zoospores amiboïdes. [Reproduction of *Vaucheria* by amoeboid zoospores.] Compt. Rend. Acad. Sci. Paris 174: 824-827. 1922.—A description of the formation and dispersal of these spores is given for both *V. geminata* and *V. hamata*.—C. H. Farr.

553. SCHAFFNER, J. H. The classification of plants. XII. Ohio Jour. Sci. 22: 129-139. 1922.—This paper completes a series dealing with the classification of plants. Synopses of the several algal phyla and a key to the orders of Algae are given. A general table of the classification of the plant kingdom on a phyletic basis is also included.—H. D. Hooker, Jr.

554. SHAW, WALTER R. *Janetosphaera*, a new genus, and two new species of *Volvox*. Philippine Jour. Sci. 20: 477-508. Pl. 1-5, fig. 1-5. 1922.—Under the name *Janetosphaera aurea*, the species that has long been known as *Volvox aureus* is given the status of a monotypic genus mainly on account of the characters of the cell membranes that were brought out by Meyer and confirmed by Janet. The author points out, as others have done, that forms have been described under the name of this species that do not belong there. A transcript of an European description of the species is supplemented by data derived from Californian material. Two new species of *Volvox* are described from the Philippines: *V. Merrilli* and *V. Barberi*. The former resembles *V. globator* of Europe and *V. perglobator* of North America, and the latter resembles *V. Rousseleti* of Africa. Both asexual and sexual phases of the new species are described. Descriptions of the 5 species retained in *Volvox* are given to facilitate comparison. Distinguishing characters of these species are presented in a key and a table.—E. D. Merrill.

555. SHAW, WALTER R. *Merrillosphaera*, a new genus of the *Volvocaceae*. Philippine Jour. Sci. 21: 87-129. Pl. 1-8. 1922.—Under the name *Merrillosphaera Carteri* the species that has been known as *Volvox Carteri* is redescribed in accordance with the characters found in very abundant material, including all phases of the life history, found at Manila. It is made the type of a genus distinguishable from *Volvox* by the absence of protoplasmic connections between the cells, by differentiation of the asexual reproductive cells in early stages of the embryos, and by the great size attained by them before division. The species was originally described from Bombay. A North American form (*Volvox Weismannia*) is considered only a variety of *M. Carteri*. An African species (*V. africanus*) and an European species (*V. tertius*) are embraced in the new genus, the former having been found also at Manila. Some European material included by Klein in *Volvox aureus* is made tentatively the basis of the species *Merrillosphaera Migulæ*.—E. D. Merrill.

556. STRØM, KAARE MÜNSTER. Freshwater algae from Caucasus and Turkestan. Nyt Mag. Naturvidenskab. 57: 1-14. Pl. 2, fig. 1-16. 1919.—A systematic account is presented

of 71 species of algae identified from collections made in Caucasus and Turkestan. The following are described as new varieties: *Cosmarium granatum* Bréb. var. *depressum*, *C. subtumidum* Nordst. var. *minor*, *C. impressulum* Elfv. var. *punctatum*.—L. H. Tiffany.

557. STRØM, KAARE MÜNSTER. Some algae from hot springs in Spitzbergen. Bot. Notiser 1921: 17–21. 1921.—A list is given of algae collected in the hot springs, Troldkilderne and Jotunkilderne, in the vicinity of Bock Bay, the temperature varying from 20–25°C.—L. H. Tiffany.

558. STRØM, KAARE MÜNSTER. The phytoplankton of some Norwegian lakes. Viden-skapsselskapets Skrifter I Mat. Naturv. Kl. 4: 1–51. 3 pl., 23 fig. 1921.—A contribution to the freshwater plankton of Norway, including an account of the plankton of the lakes investigated and a systematic list of the species and their frequency in the lakes. Of the 174 species and varieties observed 111 are Chlorophyceae, 19 Myxophyceae, 26 Diatomeae, 8 Flagellatae, 8 Peridineae, 1 Phaeophyceae. Distribution percentage in the plankton is apportioned: 49 per cent Desmidiaceae, 11 per cent Myxophyceae, 17 per cent Diatomeae, other Algae 26 per cent.—L. H. Tiffany.

559. SUESSENGUTH, KARL. Beitrag zur Kenntnis der Algenflora Südbayerns. [A contribution to our knowledge of the algal flora of South Bavaria.] Krypt. Forsch. Bayer. Bot. Ges. München 5: 362–367. 1920.—The author gives a list of 124 algae from various parts of South Bavaria, each species being accompanied by data regarding localities and, in a few cases, by descriptive notes. The species are arranged according to the following groups: Schizophyceae (7), Protomastiginae (14), Chrysomonadinae (9), Cryptomonadinae (3), Eugleninae (18), Dinoflagellatae (6), Volvocales (6), Tetrastorales (5), Protococcales (24), Ulotrichales (17), Microsporales (2), Zygnemales (9), and Heterochloridales (4). No new species are described.—A. W. Evans.

560. TAYLOR, WM. RANDOLPH. Notes on some algae from British Columbia. Rhodora 24: 101–111. 1 fig. 1922.—An annotated list is presented of the species collected in the Selkirk and Eagle Pass Mountains, with critical comments. *Rhizoclonium selkirkii* is a new species.—M. L. Fernald.

561. ZIMMERMAN, WALTER. Zur Entwicklungsgeschichte und Zytologie von Volvox. [The developmental history and cytology of Volvox.] Diss. Freiburg, 38 p. 1921.

MORPHOLOGY AND TAXONOMY OF BRYOPHYTES

ALEXANDER W. EVANS, *Editor*

(See also in this issue Entries 241, 250, 251, 256, 260, 263, 265, 266, 553)

562. ANONYMOUS. Hepatics. Moss Exchange Club Ann. Rept. [Arbroath] 26: 279–282. 1921.—Of the 53 species listed all came from the British Isles except 3,—1 from California, 1 from South America, and 1 from West Africa. Critical notes by D. A. J[ONES], H. H. K[NIGHT], W. E. N[ICHOLSON], and W. H. P[EARSON] elucidate some of the specimens distributed.—A. W. Evans.

563. ANONYMOUS. Hepatics. Moss Exchange Club Ann. Rept. [Arbroath] 27: 295–297. 1922.—The species listed number 51. The 8 exotic specimens came from South America and Tasmania, while the remaining specimens were all collected in the British Isles. Short critical notes by D. A. J[ONES], H. H. K[NIGHT], and W. H. P[EARSON] are included in the report.—A. W. Evans.

564. ANONYMOUS. Hepatics. Moss Exchange Club, Sec. II Rept. [Barmouth] 1920: 19–25. 1921.—Of the 93 species of hepatics distributed during 1920 and here listed, 12 came

from the Continent, 1 from Africa, and the others from the British Isles. D. A. J[ONES] and W. H. P[EARSON] have contributed a few critical notes.—A. W. Evans.

565. ANONYMOUS. Mosses. Moss Exchange Club, Sec. II Rept. [Barmouth] 1920: 6-18. 1921.—The report lists 145 species of mosses distributed during 1920. Most of the specimens came from the British Isles but 14 were collected on the Continent and 1 in Canada. Occasional critical notes by D. A. J[ONES], P. G. M. R[HODES], G. B. S[AVERY], W. R. S[HERRIN], and J. A. W[HELDON] are included.—A. W. Evans.

566. ANONYMOUS. *Sphagna*. Moss Exchange Club Ann. Rept. [Arbroath] 26: 271-273. 1921.—The specimens of *Sphagnum* distributed by the Club during 1920 are listed under 27 species. All the material was collected in the British Isles.—A. W. Evans.

567. ANONYMOUS. *Sphagna*. Moss Exchange Club Ann. Rept. [Arbroath] 27: 288-291. 1922.—The specimens of *Sphagnum* distributed by the Club are listed under 31 species, most of which are represented by several distinct varieties and forms. With the exception of 1 specimen from France and 3 from New Zealand the material was collected in the British Isles. A few critical notes are supplied by J. A. W[HELDON] and a new variety of *S. trichophyllum* Warnst., based on a New Zealand specimen, is provisionally proposed.—A. W. Evans.

568. ANONYMOUS. True mosses. Moss Exchange Club Ann. Rept. [Arbroath] 26: 273-279. 1921.—The species listed number 91. With the exception of 10 species from the Continent and 3 from New Zealand the list was based on material from the British Isles. Critical notes are supplied by H. N. D[IXON], W. E. N[ICHOLSON], P. G. M. R[HODES], W. G. T[RAVIS], and J. A. W[HELDON].—A. W. Evans.

569. ANONYMOUS. True mosses. Moss Exchange Club Ann. Rept. [Arbroath] 27: 291-294. 1922.—Of the 73 species listed 6 came from Switzerland, 4 from other parts of continental Europe, 1 each from California, New Zealand, and Tasmania, and the others from the British Isles. Critical notes accompanying certain specimens are by H. N. D[IXON], W. E. N[ICHOLSON], and P. G. M. R[HODES].—A. W. Evans.

570. AMANN, J. L'indice cellulaire des Fissidens européens du groupe "crassipes." [The cellular index of the European species of Fissidens belonging to the "crassipes" group.] Rev. Bryologique 48: 65-69. 1921.—The author applies his method of measuring leaf-cells by the "cellular index" [see Bot. Absts. 11, Entry 2659] to *Fissidens crassipes* Wils. and its European allies. In *F. crassipes* itself he finds much variation, the index ranging from 4,052 (cells per square mm.) to 16,876; and, on the basis of differences in cell measurements, he distinguishes the 3 groups *laxiretis*, *medioretis*, and *densiretis*. In *F. Mildeanus* Schimp., a species very close to *F. crassipes*, the cellular index ranges (in round numbers) from 5,370 to 6,611; and in *F. rufulus* Br. Eur. from 10,700 to 14,950. The figures obtained for the other species in the group, *F. Monguilloni* Thér., *F. Arnoldi* Ruthe, and *F. rivularis* Spruce, are hardly numerous enough to have much significance.—A. W. Evans.

571. ANDREWS, A. LeROY. *Hymenostomum* in North America. II. The case of *Astomum Sullivantii*. Bryologist 25: 66-71. 1922.—The author concludes that *Astomum crispum* (Hedw.) Hampe of Europe does not occur in North America, plants so referred being mostly *A. Sullivantii* B. & S. The earliest name of this latter plant is *Phascum Muhlenbergianum* Swartz, necessitating the new combination *Hymenostomum Muhlenbergianum* (Swartz) Andrews; the types both of Swartz's and of Bruch and Schimper's species have been studied. While the actual type specimen of *Astomum nitidulum* B. & S. was lost by Sullivant, a study of authentic material and of drawings leads to the conclusion that the material was hybrid in origin. The distinction between *A. crispum* and *A. Sullivantii* is largely quantitative though fairly constant, but the plants could be treated as marked geographic varieties. The author notes that the occurrence of *A. crispum* in China and Japan needs careful investigation, questions (in a foot-note) the validity of *A. multicapsulare* (Sm.) B. &

S., and states that *A. intermedium* Péterfi has not yet found a place in European bibliography.—E. B. Chamberlain.

572. ARMITAGE, E. Notes. Moss Exchange Club Ann. Rept. [Arbroath] 26: 282. 1921.—Several varieties of mosses are recorded for the first time from Herfordshire [England], and 2 old reports for the county are corrected.—A. W. Evans.

573. ARMITAGE, E. [Notes.] Moss Exchange Club Ann. Rept. [Arbroath] 27: 297, 298. 1922.—Certain published records for the hepatics of the English counties of Worcester, Stafford, and Warwick and for the mosses of the county of Hereford are corrected, having been based on incorrect determinations, and the following new records are given: *Lophocolea alata* for Worcestershire; *Calypogeia Neesiana*, *Lophozia longiflora*, and *Riccia sorocarpa* for Staffordshire; and *Eucalyx hyalinus* for Warwickshire.—A. W. Evans.

574. ARNELL, H. W. Die schwedischen Arten der Gattungen *Diplophyllum* und *Martinellia*. Pflanzegeographische Skizzen. [The Swedish species of the genera *Diplophyllum* and *Martinellia*. Plant geographical sketches.] 8 vo., 82 p., 34 fig. Göteborg, Sweden, 1922.—The present paper is the 1st of a proposed series on the distribution of liverworts in Sweden. It is based on material in the herbaria of the author, the University of Upsala, and the Royal Museum at Stockholm and thus makes no claims to be absolutely complete. Of the 2 genera discussed *Diplophyllum* is represented by 5 species in Sweden, so far as known, and *Martinellia* by 29. Under each species the distribution is noted in great detail, the separate stations being listed under the 28 political districts of Sweden. Each species is further accompanied by full notes on habitats, by a statement regarding the oldest known Swedish specimen, and often (especially in the case of recently described species) by critical remarks or descriptions. The following new combinations are proposed: *Martinellia cuspiduligera* (Nees), based on *Jungermannia cuspiduligera* Nees; *M. dentata* (Dum.), based on *Scapania dentata* Dum.; and *M. lingulata* (H. Buch), based on *S. lingulata* H. Buch. *Scapania helvetica* Gottsche, which is considered identical with *S. geniculata* Massal., is reduced to synonymy or varietal rank under *M. irrigua* (Nees) Lindb. The paper contains in addition a revision of the species occurring in Siberia and also notes on a few specimens from various scattered localities. According to the data at hand 3 species of *Diplophyllum* and 16 of *Martinellia* are now known from Siberia, including the recently described *M. tundrae* Arnell (see following entry), and 4 of these species represent additions to the flora of that country. As an addition to the flora of Norway, *M. scandica* Arnell & H. Buch [see Entry 576, this issue] is cited. The figures represent graphically the distribution of the various species according to the 28 divisions of Sweden.—A. W. Evans.

575. ARNELL, H. W. *Martinellia tundrae* Arnell, nova species. Bot. Notiser 1921: 289–291. 9 fig. 1921.—The species here described and figured under the above name was based on material collected by the author at Dudinka, Yenisei, Siberia, in August, 1876. It is assigned to the *M. undulata*-group.—A. W. Evans.

576. ARNELL, H. W., et H. BUCH. *Martinellia scandica* nov. spec. Bot. Notiser 1921: 1, 2. 1921.—The new species described under the above name was based on material from Sweden and Finland. It is assigned to the *M. curta*-group.—A. W. Evans.

577. BARTRAM, EDWIN B. Some Nova Scotia mosses. Rhodora 24: 121–124. 1922.—The author lists 35 species of mosses from central and southwestern Nova Scotia, based on his collections of July, 1921. Of these species *Sphagnum macrophyllum* Bernh., which is new to Canada, and *Grimmia Olneyi* Sulliv. are especially noteworthy. Full data regarding stations and occasional descriptive or critical notes are included.—M. L. Fernald.

578. BROECK, H., VAN DEN. De Muscineën. [The Muscineae.] Natuurwetenschapp. Tijdschr. 4: 86–88. 1922.—The author gives the distinctive features of 21 mosses and 6 hepatics found in the vicinity of Antwerp, Belgium.—A. W. Evans.

579. DUPLER, A. W. *The male receptacle and antheridium of Reboulia hemisphaerica.* Amer. Jour. Bot. 9: 285-295. Pl. 14, 46 fig. 1922.—The male receptacle of this species is normally dorsal and posterior to the female receptacle. It is typically lunate in outline and sessile. The species is monoecious, although bisexual receptacles are occasionally found. The antheridia do not develop in strict acropetal succession, as Haupt states, but show a tendency to arise centrifugally. Several variations from the usual marchantiaceous type of development were found. The male receptacle seems to be a plastic structure, and the author believes it may represent an elementary stage of a branch-system, showing transitions from the "dorsal outgrowth" type to the "composite branch-system" type.—E. W. Sinnott.

580. HERZOG, TH. *Hypnum Lorentzianum* Mol. Eine bryogeographische Skizze. [Hypnum Lorentzianum. A moss-geographical sketch.] Krypt. Forsch. Bayer. Bot. Ges. München 5. 345-353. 2 fig. 1920.—The author discusses the geographical distribution and morphological features of "*Hypnum*" *Lorentzianum* in considerable detail. The species is largely confined to the region lying between the Rhine and Inn Rivers and may be regarded as one of the character-mosses of the northern foothills of the Alps. It occupies a somewhat isolated position among European species and should be known as *Brotherella Lorentziana* (Mol.) Fleisch., the genus *Brotherella* being mainly composed of species from eastern Asia. Although Fleischer places this genus between *Rhaphidostegium* and *Sematophyllum* the author considers it more closely allied to *Heterophyllum*.—A. W. Evans.

581. [HUSNOT, T.] [Rev. of: GYÖRFFY, I. *Bryologische Seltenheiten XIII.* (Bryological anomalies.) Hedwigia 63: 48-49. 3 fig. 1921 (see Bot. Absts. 11, Entry 1634).] Rev. Bryologique 48: 77. 1921.—The reviewer shows that the author's figures of coalesced capsules in *Bryum pallescens* are very similar to figures of *B. Donianum* published by Potier de la Varde in 1920 [see Bot. Absts. 7, Entry 1977]. He adds that anomalies of this type seem to be less rare in *Bryum* than in other genera.—A. W. Evans.

582. KRAUSE, ERNST H. L. *Zweiter Nachtrag zur Rostocker Moosflora.* [Second supplement to the Rostocker Moosflora.] 8 vo., 2 p. Rostock, 1922.—The original moss flora of Rostock and the 1st supplement have already been abstracted [see Bot. Absts. 11, Entries 2268, 2269]. In the 2nd supplement 6 mosses and 3 hepatics are added to the flora, additional data regarding other species are given, and several new combinations are formed.—A. W. Evans.

583. NAVEAU, R. *Sphagnum Vandenbroeckii* n. sp. R. Nav. Natuurwetenschapp. Tijdschr. 4: 144, 145. 9 fig. 1922.—Under the above name the author describes a new species of *Sphagnum* from Ruwenzori in the Lamuri-Congo, Africa. It was based on material collected by Bequaert.—A. W. Evans.

584. PEARSON, WM. HY. *Notes on a collection of Hepaticae from Belgian Congo (ex herb. R. Naveau, Antwerp).* Natuurwetenschapp. Tijdschr. 4: 118-143. Pl. 1-18. 1922.—The present report is based on a series of specimens collected in various parts of the Belgian Congo, Africa, by Corbisier, Lacomblez, Poma, Vanderyst, and Vermoesen. The species listed number 26, of which the following are proposed as new and figured: *Acrolejeunea Orchidae*, *Eulejeunea compressistipula*, *Frullania platyflora*, *Lopholejeunea Vermoesenii*, *Mastigolejeunea Lacomblezii*, *Plagiochila fragilifolia*, *P. Naveauiana*, *P. Pomai*, *P. strictifolia*, *Prionolejeunea Corbisieri*, *P. uncatifolia*, and *Riccia radicata*. Full data regarding localities are given in each case, and many of the species are accompanied by critical remarks.—A. W. Evans.

585. POTIER DE LA VARDE, R. *Observations sur quelques espèces du genre Fissidens.* [Observations on certain species of the genus Fissidens.] Rev. Bryologique 48: 70-72. 1921. The earlier parts of the series to which this article belongs have already been abstracted [see Bot. Absts. 8, Entry 1270]. In the present part the author records *Fissidens Monguilloni* Thériot for the 1st time from the French departments of Vendée and Loire-Inférieure. He

then discusses No. 158 of Husnot's Musci Galliae. This specimen was collected in Monaco and distributed as *F. incurvus* Schwaegr.; it should, however, be referred to *F. Bambergeri* Schimp., the distinctive characters of which are enumerated.—A. W. Evans.

586. SCHADE, A. Die Lebermoosflora der Oberlausitz. [The liverwort flora of the Upper Lausitz.] Festschr. zur Feier des 75 jähr. Bestehens der Naturwissenschaftl. Ges. Isis in Bautzen. 22 p. 1921.—The liverworts of eastern Saxony (in which the Upper Lausitz is situated) and the neighboring parts of Bohemia have received the attention of several students of the Hepaticae, and the author has incorporated the results of earlier explorations with his own. The species enumerated for this region total 135, of which 5 represent additions to the flora of Saxony. Each species is accompanied by full data regarding stations and collectors. The following are among the more interesting species listed: *Calypogeia arguta* Mont. & Nees, *Hygrobiella laxifolia* (Hook.) Spruce, and *Madotheca Porella* (Dicks.) Nees. In the author's opinion the 1st represents a recent introduction while the other 2 should be regarded as probable relicts of the Glacial Period.—A. W. Evans.

587. THÉRIOT, I. Contribution à la flore bryologique du Chili. [Contribution to the bryological flora of Chile.] Rev. Chilena Hist. Nat. 25: 289-312. Pl. 23-27. 1921.—This is the 4th article published by the author under the above title; the 3rd has already been abstracted [see Bot. Absts. 4, Entry 1042]. The present report is based mainly on specimens collected by J. A. Campo, N. Costes, C. Deltor, and F. Jaffuel in various parts of Chile. The species listed number 48 and are accompanied by full data regarding localities and also, in many cases, by descriptive notes. The following species are proposed as new, Thériot being the authority except where otherwise indicated: *Barbula Costesii*, *B. fuscoviridis* Broth., *Brachysteleum Deltori*, *Fissidens Costesii*, *Funaria Costesii*, *Orthotrichum bicolor*, *Pentastichiella Jaffueli*, *Pleuroidium Costesii*, *Tortula atrata*, *T. Costesii*, and *Zygodon Jaffueli*. In addition *Pseudocrossidium pachyneuron* (Dusén) Thériot, based on *Barbula pachyneura* Dusén, is proposed as a new combination, and new varieties are described under *Fissidens Brotherianus* Par., *Macromitrium paraphysatum* Mitt., and *Tortula papillosa* Wils. Thériot's new species, 2 of his new varieties, and *Orthotrichum assimile* C. M. are figured on the accompanying plates.—A. W. Evans.

MORPHOLOGY AND TAXONOMY OF FUNGI, LICHENS, BACTERIA, AND MYXOMYCETES

H. M. FITZPATRICK, *Editor*

D. S. WELCH, *Assistant Editor*

(See also in this issue Entries 181, 183, 184, 198, 223, 410, 531, 718, 758, 780, 788, 789, 808, 812, 820, 821, 863, and those in Section Pathology)

FUNGI

588. BLUMER, S. Beiträge zur specialisation der Erysiphe horridula Lév. auf Boraginaceen. [Contributions on the specialization of Erysiphe horridula Lév. on the Boraginaceae.] Centralbl. Bakt. II Abt. 55: 480-505. Fig. 1. 1922.—A biological and morphological study of the forms of *Erysiphe cichoracearum* on the Compositae and Boraginaceae is reported. The forms on the Boraginaceae are placed under a separate species, *E. horridula*; the weaker specialization and the more uniformly 3-spored asci of the forms on the borages are taken as the bases of separation.—Anthony Berg.

589. BOURDOT, H., et A. GALZIN. Hyménomycètes de France. (VII Stereum) suite. [Hymenomycetes of France.] Bull. Trimest. Soc. Mycol. France 37: 117-130. 1921.—The author continues his treatment of the genus *Stereum*, describing 17 species. [See also Bot. Absts. 10, Entry 1206.]—D. S. Welch.

590. BOURDOT, H., et L. MAIRE. Notes critiques sur quelques Hyménomycètes nouveaux ou peu connus. [Some new or little known Hymenomycetes.] Bull. Trimest. Soc. Mycol. France 36: 69-85. 1 fig. 1920.—Species from the following genera are described and discussed: *Platyglœa*, *Evidia*, *Tremella*, *Sebacina*, *Exidiopsis*, *Bourdodia*, *Ditiola*, *Clavaria*, *Corticium*, *Peniophora*, *Grandinia*, *Asterostromella*, *Hypochnus*, *Phylacteria*, *Tomentella*, *Trametes*, *Leptosporus*, *Irpez*, *Poria*, *Xanthochrous*.—D. S. Welch.

591. BROQ-ROUSSEAU, M. Les recherches mycologiques en médecine vétérinaire. [Mycological researches in veterinary medicine.] Bull. Trimest. Soc. Mycol. France 37: 99-103. 1921.—A laboratory for veterinary research has been established by the minister of war. Attention is called to the fact that many diseases of horses are caused by fungi. The following are reported: Favose thrush caused by a fungus referred to *Achorion gypseum* Bodin. Microsporic thrush, of which 2 cases are reported; from one of these Sabouraud isolated *Microsporon lanosum*, and in another Bodin describes *M. equinum*. Four species of *Trichophyton* have been reported to cause Trichophytic thrush. The perfect stages of these forms are for the most part unknown. It has been suggested that they belong to the Gymnoascaceae. Sporotrichosis is caused in horses as in man by *Sporotrichum Beurmanni* Matruchot & Ramond. Epizootic lymphangitis, caused by a *Cryptococcus* of uncertain relationships, is confined to Africa. The streptothrix group is widely distributed and contains among other organisms the one causing actinomycosis of man and animals. A *Streptothrix* has been found causing decomposition in grain and forage. Mouldy or decayed feed has been held responsible for cases of severe poisoning.—D. S. Welch.

592. BUBÁK, FR. Fungi aus Mesopotamien und Kurdistan, sowie Syrien und Prinkipo. Nachträge. [Fungi from Mesopotamia and Kurdistan, also Syria and Prinkipo.] Ann. Naturhist. Mus. Wien 34: 69. 1921.—Two species, *Tichothecium erraticum* Mass. and *Lindauopsis* sp., are added to a preceding article [op. cit. 28: 189].—A. S. Hitchcock.

593. BUCHEIM, ALEXANDER. Zur Biologie von *Uromyces Pisi* (Pers.) Winter. [On the biology of *Uromyces Pisi*.] Centralbl. Bakt. II Abt. 55: 507-508. 1922.—In culture studies made near Moscow uredospores of *Uromyces Pisi* from *Lathyrus pratensis* L. infected *Pisum sativum* L., *P. arvense* L., *Lathyrus Nissiola* L., and *L. articulatus* L. This confirms Jordi's conclusion that the fungus on *Pisum* and *Lathyrus* is the same.—M. A. Raines.

594. CHIFFLOT, J. Sur quelques troubles provoqués par l'ingestion de *Inocybe rimosa* B. [Trouble caused by eating *Inocybe rimosa*.] Bull. Trimest. Soc. Mycol. France 37: 139-140. 1921.—*Inocybe rimosa* although commonly regarded as an edible species is reported to be poisonous when eaten in large quantity.—D. S. Welch.

595. CHIFFLOT, [J.] Un champignon de 20 kilos. [A fungus weighing 20 kilos.] Bull. Trimest. Soc. Mycol. France 37: 138-139. 1921.—A very large specimen of *Polyporus sulfureus* was sent to the author for identification.—D. S. Welch.

596. HEDGCOCK, GEORGE G., and GLENN GARDNER HAHN. Two pine cone rusts and their new cronartial stages. Part I. *Cronartium strobilinum* (Arthur) Hedgc. and Hahn, comb. nov. Phytopathology 12: 109-116. Pl. 5. 1922.—A rust of the cones of *Pinus palustris* formerly attributed to *Caecoma strobilina* Arth. has been known to occur in Florida and nearby territory since 1892. It has also been found on cones of *Pinus heterophylla* throughout the same range. Recently the authors have found that the aecial sori possess a peridium like the true *Peridermiums*. A *Cronartium* which occurs on the leaves of *Quercus virginiana* and of *Q. geminata* has been proved, by cross inoculations in the greenhouse, to be the alternate stage of the fungus. The leaves of several other species of *Quercus* and also species of *Castanea* have been successfully inoculated with aeciospores from the pine cones; but teliospores were not produced on deciduous leaves. The fungus is redescribed as *Cronartium strobilinum* (Arth.) comb. nov.—B. B. Higgins.

597. HEDGCOCK, GEORGE G., and N. REX HUNT. Two pine cone rusts and their new cronartial stages. Part II. *Cronartium conigenum* (Pat.) Hedg. & Hunt, comb. nov. *Phytopathology* 12: 116-122. Pl. 6. 1922.—The aecial sori of *Caeoma conigenum* which occur on the cones of *Pinus chihuahuana* possess a true peridium. The alternate stage is a *Cronartium* which occurs on the leaves of *Quercus Emoryi* and *Q. hypoleuca*. The fungus is redescribed as *Cronartium conigenum* (Pat.) comb. nov.—B. B. Higgins.

598. HUNTER, ALBERT C. A pink yeast causing spoilage in oysters. U. S. Dept. Agric. Bull. 819. 24 p. 1920.—The organism causing a pink color in shipped oysters is a yeast-like fungus belonging to the group *Torulæ*. It was found in large numbers in the oyster-house and on utensils in and about the house, less frequently in oysters before they were brought to the house. For the purpose of preventing the infection of opened oysters, the house and utensils should be washed occasionally, through the opening season, with a 1-2500 formaldehyde solution (formalin 1-1000).—D. S. Welch.

599. LEBEDIEVA, L. A. Fungi novi in horto botanico Petropolitano annis 1921-22 collecti. [New fungi collected in 1921-22 in the botanical garden of Petrograd.] *Notulae Systematicae Inst. Cryptogamico Hort. Bot. Petropolitani* 1: 62. 1922.—A new species of the *Sphaeropsidaceae* occurring on dead branches of species of *Spiraea* and *Sorbaria* is described. It is considered the pycnidial stage of *Scleroderris Spiraeae* Rehm, which was found on the same branches. This fungus, named *Sirodiplospora Spiraeae* Lebed., is very close to *Sirodiplospora sambucina* Naoumov on *Sambucus racemosa*, which seems to be the pycnidial stage of *Scleroderris sambucina* Naoumov. (Both forms were discovered in Tsarskoie Sielo near Petrograd and described by N. Naoumov.)—A. Jacewski.

600. VUILLEMIN, M. P. Quelques formes thermophiles de l'*Aspergillus glaucus*. [Some heat-resistant forms of *Aspergillus glaucus*.] *Bull. Soc. Sci. Nancy* 1: 15-16. 1920.—Four races of *Eurotium repens* enduring a temperature of 38°C. were studied. The material was secured from (1) pus from a felon; (2) gangrenous lesion in frozen feet; (3) inflamed groin; (4) lymph of the cheek. The last case was conclusive because the perithecia developed in the midst of living tissues, were extracted with every precaution, and by culture reproduced *Aspergillus glaucus* and the perithecia characteristic of a variety of *Eurotium repens*.—A. Chaze.

LICHENS

601. KEISSLER, KARL. Systematische Untersuchungen über Flechten-Parasiten und lichenoiden Pilze. [Systematic investigations on parasitic lichens and lichen-like fungi.] *Ann. Naturhist. Mus. Wien* 34: 70-78. 1921.—This is Part 2, nos. 12-20 of the contribution [1st part in *Beih. Bot. Centralbl.* 37: 263. 1920]. The following are discussed: 12. *Didymella tiliaginea* and *Sphaerulina tiliaris*; 13. *Mycarthopyrenia Sorbi* n. gen. et n. sp., on *Sorbus Aucuparia*, Austria; 14. *Agyrium hepaticolum* n. sp., Austria; 15. *Pleionoscutula Brouardi*; 16. *Durella Lecideola* var. *coeruleo-viridis* n. var., Poland; 17. *Lecanidion Bachmannianum* n. sp., Poland; 18. *Cyrtidula nostochinea*; 19. *Cyrtidula pteleodes*; 20. *Aposphaeria Cladoniae* and *Phoma uncialicola*.—A. S. Hitchcock.

602. STEINER, J. Lichenes aus Mesopotamien und Kurdistan sowie Syrien und Prinkipo. [Lichens from Mesopotamia and Kurdistan, also Syria and Prinkipo.] *Ann. Naturhist. Mus. Wien* 34: 1-68. 1921.—An annotated list is presented of lichens collected by Handel-Mazzetti, with numerous new forms, varieties and species, and new combinations. The new species are: *Verrucaria emergens*, Syria; *V. syriaca*, Syria; *V. sordidula*, Mesopotamia; *Thelidium myriocaroides*, Syria; *Staurothele praecedens*, eastern Kurdistan; *Biatorella leucothallina*, near Aleppo; *Acarospora Bornmülleri*, Mesopotamia; *A. Handelii*, Mesopotamia; *Gonohymenia mesopotamica*, Mesopotamia; *Lecanora kurdistanica*, western Kurdistan; *L. amylophora*, Syria; *L. radians*, Bitlis [Armenia]; *L. subfarinosa*, Mesopotamia; *L. syriaca*, Syria; *L. kjachtensis*, northern Mesopotamia and Kurdistan; *L. ferruginea*, Syria; *Caloplaca fuscula*, Mesopotamia; *C. Handelii*, Mesopotamia.—A. S. Hitchcock.

BACTERIA

603. AYERS, S. HENRY, and COURTLAND S. MUDGE. **The streptococci of the bovine udder.** IV Studies of the Streptococci. Jour. Infect. Diseases 31: 40-50. 1922.—Methods of isolation and the special technique of the cultural methods used for the differentiation of the different types are described. *Streptococcus mastitidis* was found to be the prevalent type in the udder of the cow, it being found in normal animals. It is differentiated from the closely allied *S. pyogenes* on the basis of final pH and difference in ability to hydrolyze sodium hippurate. It is not believed that *S. mastitidis* is pathogenic for man when consumed in milk. Due to the small amount of acid produced in test substances, a new species has been described and named *Streptococcus acidominimus*.—R. V. Allison.

604. FABRY, PAUL. Note sur le Bacille coli modifié ne produisant plus d'indol. [A note on a modified form of *Bacillus coli* which does not produce indol.] Compt. Rend. Soc. Biol. 87: 113-115. 1922.

605. LACY, G. R., and A. C. MURDOCH. **Encapsulated non-gas-forming bacilli.** Jour. Infect. Diseases 31: 64-71. 1922.—The morphological, cultural, and immunological characteristics of an encapsulated, non-gas-forming, aerobic bacillus as isolated from 3 patients suffering with some pathologic condition of the genito-urinary tract are presented. It was not found possible to determine whether the organism was the primary etiologic factor or only a secondary invader. The brief literature upon this type of organism is reviewed and the need of further study of the general group emphasized.—R. V. Allison.

PALEOBOTANY AND EVOLUTIONARY HISTORY

E. W. BERRY, *Editor*

(See also in this issue Entries 131, 207, 227, 262, 543, 914)

606. BERRY, EDWARD W. **Additions to the flora of the Wilcox group.** U. S. Geol. Surv. Professional Paper 131: 1-21. Pl. 1-18. 1922.—Additions to the lower Eocene flora of the Mississippi embayment region are described. Plant lists from new localities, various previously known species, taxonomic changes, and the following new species are included: *Marchantites stephensoni*, *Acrostichum* sp., *Cupressinoxylon wilcoxense*, *Palmocarpon butlerensis*, *Artocarpoides balli*, *Menispermites cebathoides*, *Monocarpellites perkinsi*, *Sterculia wilcoxensis*, *Helictoxylon wilcoxianum*, *Laurus verus* (fruits), *Laurinoxylon wilcoxianum*, and *Pterobalanus texanus* (a new genus of winged fruits).—E. W. Berry.

607. BERRY, EDWARD W. **Saccoglottis, recent and fossil.** Amer. Jour. Sci. 4: 127-130. 1922.—*Saccoglottis tertiaria* n. sp. from the Pliocene of Bolivia is described and *S. amazonica* is recorded from Panama Bay. Distribution and means of dispersal are discussed.—E. W. Berry.

608. BERRY, EDWARD W. **The geologic evidence of evolution.** Sci. Monthly 15: 97-118. 1922.—This article is a brief summing up in non-technical language of the geological evidence of evolution.—“Evolution is not a theory of origins, nor an article of scientific faith, but an indisputable fact.” It should not be confused with the various theories that have been proposed to explain its factors or mode of operation.—The first man to see the transformation of species was Waagen, an Australian geologist who studied the minute changes in the successive species of *Ammonites* in the successive layers of the Jurassic. Other groups show the same thing; *Archaeopteryx* of the Jurassic, the elephants of the Miocene and Pliocene, the horses of the Cenozoic, and finally the record of man himself, with special mention of the recently discovered skeletons.—L. Pace.

609. CHANEY, R. W. Notes on the flora of the Payette formation. Amer. Jour. Sci. 4: 214-222. 1922.—A partial account is presented of the flora of the Payette formation of Idaho and adjacent areas in Oregon and which was formerly considered to be upper Eocene in age. The author makes additions to this flora—bringing the total number of species up to 49, discusses the environment which they indicate, and concludes that the age is Miocene.—E. W. Berry.

610. FRENTZEN, K. Beiträge zur Kenntnis der fossilen Flora des südwestlichen Deutschland. [Contribution to the fossil flora of southwestern Germany.] Jahresber. u. Mitteil. Oberrhein. Geol. Ver. N. F. 10: 63-73. 1921; 11: 1-14. 1922.—The 1st contribution gives an account of the author's studies of late Triassic florules from Adelshausen, Rappersweier, and Malsch in southwestern Germany. The 2nd consists of a brief comparison of the Keuper flora of Baden, Thuringia, and adjacent regions with that contained in the Schilf sandstone of the same areas.—E. W. Berry.

611. GILKINET, ALF. Flore fossile des Psammites du Condroz. [Fossil flora of the upper Devonian of Condroz.] Mém. Soc. Géol. Belgique 1921-1922: 1-21. Pl. 1-13. 1922.—The following typical upper Devonian species from Condroz, Belgium, are described: *Sphenopteris condrosorum*, *S. flaccida*, *S. Schimperiana*, *Triphyllopteris elegans*, *Archaeopteris Roemeriana*, *Asterocalamites scrobiculatus*, and *Lepidodendron nothum*.—E. W. Berry.

612. GILKINET, ALF. Plantes fossiles de l'argile plastique d'Andenne. [Fossil plants from the plastic clay of Andenne.] Mém. Soc. Géol. Belgique 1921/1922: 23-40. Pl. 14-17. 1922.—The following species of Aquitanian or lower Miocene age are recorded from the clay pits of Champseau near Andenne, Belgium: *Sphaeria lignitum*, *Lygodium Gaudini*, *Salvinia cordata*, *Sequoia Couttsiae*, *Taxodium distichum miocenicum*, *Phragmites oeningensis*, *Rhizocaulon gypсорum*, *Stratiotes Websteri*, *Alnus Kefersteini*, *A. gracilis*, *Populus glandulifera*, *Nyssa* sp., *Comptonia Schrankii*, *Cinnamomum Scheuchzeri*, *C. lanceolatum*, *Gardenia Wetzleri*, *Echitonium cuspidatum*, *Acer trilobatum* and its variety *cuspidatum*, and *Ilex Dardenniana*. The last is the only new species. From these same clays but of unknown age are described cones of *Pinus sylvestris*, *P. Laricio*, and *P. Pinaster*? These last are late Tertiary or Pleistocene.—E. W. Berry.

613. HYLANDER, C. J. A Mid Devonian Callixylon. Amer. Jour. Sci. 4: 315-321. 1922.—The author describes *Callixylon Marshii* n. sp., a type of Cordaitan wood with segregated groups of pits, and in this species showing growth rings. The specimen is from the Devonian of 18 Mile Creek, New York.—E. W. Berry.

614. IWASAKI, C. A fundamental study of Japanese coal. Tech. Rept. Tohoku Imp. Univ. 24: 1-41. Pl. 1-9. 1922.—A continuation of the author's previously published work on the technology of Japanese coals.—E. W. Berry.

615. JOHANSSON, NILS. Die Rätische Flora der Kohlengruben bei Stabbarp und Skromberga in Schonen. [The Rhaetic flora of the coals of Stabbarp and Skromberga in Schonen] K. Svensk. Vetenskap. Akad. Handl. 63⁴: 1-78. Pl. 1-8. 1922.—A monographic account is given of the Rhaetic or late Triassic flora of these 2 localities in southern Sweden. The flora comprises 4 Equisetales, 1 Lycopodiales, 18 Filicales, 11 Cycadophyta, 7 Ginkgophyta, 6 Coniferophyta, and 2 plants of unknown affinities. It consists for the most part of well known Rhaetic types. Considerable is added to our knowledge of some of these and the following are described as new: *Cladophlebis Svedbergii*, *C. sublobata*, *C. Sewardii*, *C. divaricata*, *Cycadolepis rugosa*, and seeds of the cycadophyte genus *Nilssonina*.—E. W. Berry.

616. JOHANSSON, NILS. Pteryopteris eine neue Farngattung aus dem Rät Schonen. [Pteryopteris, a new fern genus from the Rhaetic of Sweden.] Ark. Bot. 17: 1-6. Pl. 1. 1922.—A new genus of ferns based upon *Polypodites*? *Angelini* Nathorst is described from the

upper Triassic of southern Sweden. Comparisons are made with *Laccopteris* and *Dictyophyllum* and the author concludes that the systematic position of *Pterygopteris* cannot be satisfactorily determined at present.—*E. W. Berry.*

617. KEIDEL, J. Sobre la distribución de los depósitos glaciares del Pérmico conocidos en la Argentina y su significación para la estratigrafía de la serie de Gondwana y la paleogeografía del hemisferio austral. [On the distribution of Permian glacial deposits in Argentina and their significance in the paleogeography and stratigraphy of the Gondwana series.] Bol. Acad. Nacion. Cien. Córdoba 25. 1922.—A summary account is given of the occurrences of Permian glacial deposits in Argentina and a discussion of the contained *Glossopteris* flora and of the paleogeography of Gondwana Land.—*E. W. Berry.*

618. KNOWLTON, F. H. A fossil dogwood flower. Amer. Jour. Sci. 4: 136-138. 1922.—A fossil flower, *Cornus speciosissima* n. sp., from the Fort Union (lower Eocene) of Wyoming is described.—*E. W. Berry.*

619. KODAIRA, R. Fossil nut-shells of *Juglans Sieboldiana Maximovicz* in the lignite of Asahiyaama, near Nagano City, Province of Shinano. Jour. Geol. Soc. Tokyo 23: 1-8. Pl. 12. 1921.—The age is Pleistocene; the remaining facts are set forth in the title.—*E. W. Berry.*

620. KRÄUSEL, R. Der Bau des Wundholzes bei fossilen und rezenten Sequoien. [The structure of traumatic wood in fossil and recent Sequoias.] Senckenbergiana 3⁵: 135-142. 1921.—The author discusses the relationships between fossil and recent species of *Sequoia* and *Taxodium* as shown by the structure of the traumatic areas of the wood, referring several fossil types such as *Cupressinoxylon wellingtonioides* Kräusel, *C. taxodioides* Platen, *C. Holdenae* Seward, *Taxodioxylon sequoianum* Kräusel, and *T. Credneri* Platen to *Sequoia*.—*E. W. Berry.*

621. KRÄUSEL, R. Die Nahrung von Trachodon. [The food of Trachodon.] Palaeontol. Zeitschr. 4: 80. 1922.—From a mass of sandy carbonaceous matter inside the cadaver of the dinosaur *Trachodon* the author identifies the needles of *Cunninghamites elegans*, fragments of coniferous and dicotyledonous foliage, seeds or fruits, pollen, and eyes of water insects.—*E. W. Berry.*

622. KRÄUSEL, R. Fossile Hölzer aus dem Tertiär von Süd-Sumatra. [Fossil woods from the Tertiary of southern Sumatra.] Verhandl. Geol. Nederland. u. Kolonien, Geol. Ser. 5: 231-287. Pl. 1-7, fig. 1-29. 1922.—The following new species of woods from the Tertiary, mostly Miocene, of Java, are described: *Djambioxylon sumatrense*, possibly belonging to the Combretaceae; *Dipterocarpozylon Tobleri*, and 2 unnamed forms of the same genus; *Sapindoxylon Janssonii*; *Anacardioxylon Mollii*, *Caesalpinioxylon palembangense*; *Palmoxylon taudjungense*; and *Tarrietioxylon sumatrense*, which is related to the existing genus *Tarretia* of the Sterculiaceae.—*E. W. Berry.*

623. KRÄUSEL, R. Über einige fossile Koniferenhölzer. [On several fossil coniferous woods.] Senckenbergiana 3⁵: 129-135. 1921.—The author discusses *Paläotaxodioxylon Grünwettersbachense* Frentzen, a coniferous wood from the Bunter (lower Triassic) of Baden advancing arguments tending to prove its Araucarian affinity instead of its supposed Abietinean relationship as suggested by its describer. The author discusses also *Pityoxylon Schenkii* Kraus, a Tertiary species, showing its relationship with the *Sequoia* rather than with the *Pinus* types of fossil woods.—*E. W. Berry.*

624. NATHORST, A. G. Einige Psymgophyllum-Blätter aus dem Devon Spitzbergens. [Several Psymgophyllum leaves from the Devonian of Spitzbergen.] Bull. Geol. Inst. Upsala 18: 1-8. Pl. 1. 1922.—*Psymgophyllum Williamsoni* and a new species, *Psymgophyllum? pusillum*:(Ginkgoales), from the upper Devonian of Spitzbergen are described.—*E. W. Berry.*

625. ROUND, EDA M. *A Crossotheca from the Rhode Island Carboniferous.* Amer. Jour. Sci. 4: 131-135. 1922.—*Crossotheca nana*, a new species, from the Carboniferous of the Narragansett basin in Rhode Island is described and compared with various European species.—E. W. Berry.

626. SEAWARD, A. C. *Fossil plants from the Tanganyika Territory.* Geol. Mag. 59: 385-392. Pl. 17. 1922.—*Eretmophyllum?*, *Ulmannia*, and *Voltzia*, all poorly preserved, and, according to the author indicating a Triassic age, are recorded from the Tanganyika district in Africa.—E. W. Berry.

627. THOMAS, H. H. *On some new and rare Jurassic plants from Yorkshire.* V. Fertile specimens of *Dictyophyllum rugosum* L. and H. Proc. Cambridge Phil. Soc. 21: 110-116. Pl. 1. 1922.—The sporangial characters and the venation seem to indicate that the nearest living relative of the Jurassic *Dictyophyllum rugosum* is the modern *Cheiropleuria bicuspis*.—Michael Levine.

628. WENZ, W. *Das Mainzer Becken und seine Randgebiete.* [The Mainz basin and surroundings.] Willy Ehrig: Heidelberg. 1921.—In this account of this classic region for Tertiary geology the author lists and figures the fossil plants from the various Tertiary horizons represented in that region.—E. W. Berry.

(See also in this issue Entries 4, 17, 23, 24, 31, 57, 72, 82, 87, 90, 97, 115, 116, 117, 143, 152, 153, 165, 166, 169, 171, 181, 198, 203, 285, 335, 343, 345, 358, 366, 402, 420, 422, 428, 430, 439, 442, 452, 461, 464, 466, 473, 474, 481, 487, 503, 542, 591, 732, 758, 766, 771, 789, 790, 811, 815, 821, 844, 848, 896)

DISEASES CAUSED BY FUNGI

629. ANONYMOUS. *Cocoe rot.* Jour. Jamaica Agric. Soc. 26: 62-64. 1922.—A wilt and tuber rot of cocoes or tancias (*Colocasia* sp.) due to a vascular parasite (*Hormiscium Colocasiae* Ashby) has caused severe losses to the crop in Jamaica.—John A. Stevenson.

630. ANONYMOUS. *Potato blight.* Jour. Jamaica Agric. Soc. 25: 371-373. 1922.—A serious epidemic of potato blight (*Phytophthora infestans*) due to wet weather and late planting reduced the crop from one half to two thirds. Lowland plantings escaped the disease. Spraying with Bordeaux mixture is recommended.—John A. Stevenson.

631. ALLEN, W. J., and J. M. ARTHUR. *Orchard experiments.* Sprays for peach curl on trial at Yanco. Agric. Gaz. New South Wales 33: 442-446. 2 fig. 1922.—Lime-sulphur on dormant trees controlled peach leaf curl effectively. Spraying when the buds were bursting was less effective and still less so when the buds were "pinking." A 2nd spraying, after the 1st dormant spraying, showed no increased efficiency. Results indicated that lime-sulphur diluted more than the standard formula (1 to 7) was effective. Further trials are needed.—L. R. Waldron.

632. BAUDYŠ, E. *Plísen bramborová.* [Late blight of potato.] Naše Snahy 9: 111-113. 1921.—All varieties are not equally affected by this disease. In comparative experiments which were performed in an experimental field on the Czecho-Moravian plateau the most susceptible variety was "Up-to-date," which was practically destroyed by the disease.

Slightly less susceptible were the varieties Bílý semenáč, Viktorka, Magnum bonum, Holandeské ranné, Kaplanka, Jiřiny, and Industrie. About 15 per cent of diseased tubers were found in the varieties Prof. Märcker, Potentat, Zlocien, Erfolg, Hassia, Ceres, Phönix, Cedan, Gracia, Pyselsky, Český, Skrobák, and Silesia. Varieties almost entirely healthy were Pac, Galathea, Prof. Woltman, Zelenač, Regent, Koruna, Vločkové, Swietéz, Gedymin, Svatová, Clavské, Deodara, and Topor. In the experimental field in Moravia the variety Prof. Woltman had about 50 per cent of diseased tubers; Koruna, 15 per cent; and Zlocien, about 25 per cent. The first 2 varieties were resistant in the experimental field on the Czecho-Moravian plateau, and the 3rd variety was slightly susceptible. Spraying with Bordeaux mixture is recommended for the control of the disease.—*E. Baudyš*.

633. [BAUDYŠ, E., a FR. STRAŇÁK.] Moření osiva proti plísni sněžné. [Treatment of the seed against snow mold.] Československý Zemědělec 3: 133-134. 1921.—The damage done by this disease (*Fusarium nivale*) is estimated to be 20 per cent, which in 1920 amounted to about 1,800,000 quintals of grain. In some places the damage is as high as 80 per cent. The disease attacks rye, wheat, and frequently winter barley. For control are recommended sublimate, uspulium, and fusariol. According to Baudyš, treatment with sublimate is most effective.—*E. Baudyš*.

634. BRERETON, W. LE GAY, and C. O. HAMBLIN. Black spot of the vine (*Gloeosporium ampelophagum*). Experiments with controls, 1920-21. Agric. Gaz. New South Wales 33: 433-436. 3 fig. 1922.—The experiments were conducted (1) to determine the best winter swabs and sprays, (2) to test summer control sprays, and (3) to test late season sprays for ripening fruit. Only (1) is reported. The winter swab,—sulphate of iron and sulphuric acid,—delayed bursting of the buds about 10 days. Bordeaux spraying controlled downy mildew successfully. Winter spraying or swabbing did not control black spot at Yanco as the disease did not appear until late spring or early summer. Swabbing reduces the total amount of infective material upon the vines and so provides against an early attack of the disease.—*L. R. Waldron*.

635. BURGER, O. F., and H. C. PARHAM. Peronospora disease of tobacco. Florida State Plant Bd. Quart. Bull. 5: 163-167. 1 fig. 1921.—During the latter part of March and the beginning of April, *Peronospora Hyoscyanii* De Bary was noticed for the 1st time in Florida (Gadsden County). The disease may have been introduced from Sumatra. Large brown spots 0.5-1 inch in diameter develop on the leaves. At first these spots are yellowish green; later they have a water-soaked appearance; and finally they become brown and papery. The brown spots soon drop out, leaving holes in the leaf. Plants grown under slats and cheese cloth were infected most, slat-shade plants less, and sun-grown tobacco least. It is believed that spraying the seedbeds with 2-2-50 Bordeaux mixture may control the disease. It is impracticable to spray plants which have attained a height of 18-24 inches. The disease is confined to the sand leaves, and the loss is probably not more than 1 per cent of the crop.—*J. C. Th. Uphof*.

636. CASTRO, CARLOS. Enfermedades del jitomate. [Tomato diseases.] Bol. Camara Agric. Nacion. Leon [Mexico] 94: 4-6. 1922.—*Fusarium Lycopersici* and *Phytophthora infestans* attack the tomato.—*John A. Stevenson*.

637. CHASE, W. W. Experimental dusting and spraying of peaches for 1919. Georgia State Bd. Entomol. Circ. 30. 13 p. 1920.—Results showed that dusts of sulphur, lime, and lead arsenate gave as good results in the brown rot control as liquid sprays and that the dusts were better for scab control. Curculio control on varieties as late as Elberta was not satisfactorily effected by dusts or sprays as the season was abnormal in rains. The amount of arsenate of lead recommended against curculio is 5 per cent.—*T. H. McHatton*.

638. CLEPERRI, R. Il marciume delle mele cotogne. [A rot of quince.] Riv. Patol. Veg. 12: 12-17. 1922.—A rot of quinces was found to be caused by *Penicillium crustaceum* (L.) Fries. Various anomalous forms of the fungus are described.—*F. M. Blodgett*.

639. COTTON, A. D. Potato pink rot: a disease new to England. Jour. Ministry Agric. Great Britain 28: 1126-1130. 1922.—The occurrence of the pink rot (*Phytophthora erythroseptica* Pethyb.) disease of potatoes was noted in 7 localities in 2 districts. Though this is the 1st discovery of the disease in England it is not necessarily implied that it then occurred in England for the 1st time; it may have been present and mistaken for blight in former years.—Affected plants present a “wilted” appearance and the tubers generally rot, the rot progressing from the stem to the eye end of the tubers.—M. B. McKay.

640. DOUGLAS, BRUCE. A new *Alternaria* spot of tomatoes in California. Phytopathology 12: 146-148. Fig. 1. 1922.—A peculiar spotting of tomato fruits that has been quite prevalent during the damp weather of late fall in California, has been found to be due to a species of *Alternaria*. On the fruits the spots are brown, circular in outline, and somewhat sunken but firm. Later the spots become covered with a dark velvety growth of *Alternaria* spores. Inoculations from pure cultures of this fungus were made by placing spores suspended in sterile water in droplets on the uninjured green fruits. Spots developed in 10-21 days.—B. B. Higgins.

641. DUFRENOY, J. Les maladies du melon. [Diseases of cantaloupes.] Ann. Épiphyties 7: 405-420. Fig. 1-16. 1921.—Cantaloupes grown in France suffer very much from a wilt disease, as many as 90 per cent of the plants being sometimes destroyed. A soil *Fusarium* was constantly isolated from diseased organs; it was successfully inoculated from cultures to seedlings, causing characteristic wilting, and reisolated to agar.—From morphological and cultural characters it is best referred to as *Fusarium Solani* var. *cyaneascens* subvar. *melonis*.—Bacteria are always associated with *Fusarium*, infecting tissues in advance of the hyphae.—Resistant strains of cantaloupes should be bred from such individuals as prove *Fusarium*-resistant in badly infected fields. Resistance was proved to be due to rapid formation of suber, walling out infected wounds.—J. Dufrenoy.

642. GREGORY, C. T. The relation of rain to the formaldehyde treatment of onion smut. Phytopathology 12: 155-156. 1922.—Field results with the drip method formaldehyde treatment for onion smut (*Urocystis Cepulae* Frost) indicate that excessive rain at the time of or just after planting may reduce the beneficial effects of the treatment.—B. B. Higgins.

643. GRUYER, P. Observations sur la biologie du *Tuberculina persicina* Ditm. [Observations on the biology of *Tuberculina persicina*.] Bull. Trimest. Soc. Mycol. France 37: 131-133. 1921.—*Tuberculina persicina* Ditm. is parasitic upon the aecidia of *Endophyllum Euphorbiae*. The parasite delays or prevents the development of the aecidiospores. It is suggested that it might be used as an agent for the control of certain Uredinaceous pests.—D. S. Welch.

644. HOPKINS, E. F. Varietal susceptibility of the Yellow Bellflower apple to cedar rust. Phytopathology 12: 190-192. Fig. 1. 1922.—Aecia, identified as *Gymnosporangium Juniperi-virginianae* Schw., were found to be very prevalent on twigs of the Yellow Bellflower apple while none were found on any trees of the other varieties in the orchard.—B. B. Higgins.

645. KUTIN, AD. Snět prosořá (*Ustilago Panicis-miliacei* Vrt.). [Millet smut and a method of its control.] Ochrana Rostlin 1: 20-22. Fig. 1. 1921.—Millet smut may be entirely controlled with chemicals or by throwing the seed through the fire. In eastern Bohemia the latter method is applied as follows: As many straw torches are made as might be necessary. They are made from small bundles of long straw tied with ropes of twisted straw. Two men are necessary to carry out the operation; one takes a straw torch in each hand, lights them, and holds them about 1 m. above the ground. The torches have to be held close together so that a broad flame is obtained. The other man pours the seed slowly through the flame. The method is rapid, cheap, and effective. In the district of Kralóve-Hradek (Königsgrätz) burning is done in a sieve over the flame, and in Moravia the seed is thrown directly into the fire made from short pieces of straw. Neither treatment affects the germination.—E. Baudyš.

646. LEWIS, A. C., and W. W. CHASE. Control of curculio and brown rot of peaches. Georgia State Bd. Entomol. Circ. 34. 4 p. 1921.—A spray schedule is given accompanied by a discussion of the relation of curculio to brown rot.—*T. H. McHatton*.

647. LINE, J. A note on the biology of the "crown-gall" fungus of lucerne. Proc. Cambridge Phil. Soc. 20: 360-365. 1921.—The author confirms the work of other students and ascribes the disease to *Urophlyctis Alfalfae* Lagerh. The name "marble gall" is again suggested to distinguish it from the crown gall of bacterial origin. The galls of the lucerne are hypertrophied buds or bud parts.—*Michael Levine*.

648. McCLELLAND, T. B. The coffee leaf-spot in Porto Rico. Porto Rico Agric. Exp. Sta. Bull. 28. 12 p., pl. 1-4. 1921.—The coffee leaf-spot due to *Stilbella flavida* causes heavy losses in Porto Rico. In the higher altitudes with heavy rainfall defoliation results from the disease and many groves have been practically destroyed. An experiment was carried out on a portion of 1 of the plantations in which the disease was prevalent. In an area of about 2 acres all coffee trees were cut back to low stumps and all brush and weeds cleared out. Blank spaces were replanted. Bananas were planted around the edges of the plot to prevent the fungus from working in from adjoining infected trees. An effort was made to keep the area free of weeds, particularly those which were hosts of the fungus. The owners failed to carry out instructions as to weeding and even brought in diseased seedlings. Nevertheless, results were promising since at the end of nearly 4 years good yields were being obtained from the experimental plot in contrast to surrounding portions of the plantation, where yields were negligible.—*John A. Stevenson*.

649. MCCLINTOCK, J. A. Peach disease control. Georgia Agric. Exp. Sta. Bull. 139. 30 p., 6 fig. 1921.—The control of brown rot (*Sclerotinia fructigena* (Pers.) Nort.) on peaches is dependent upon the control of the curculio (*Conotrachelus nenuphar* Herbst.) as 90 per cent of the brown rot infections occur at curculio injuries. Mummied fruit left on trees and twig cankers are important sources from which conidia are disseminated in the spring. The blossom-blight form is the 1st indication of the disease in the spring. Blighted blossoms remain attached to the trees throughout the season and form sources of infection, and the growth of the fungus from the blighted blossoms into the twigs is one of the chief sources of canker formation and the wintering over of the disease. Thoroughly clearing the orchard after harvest coupled with spraying during the growing season will give effective control. Scab (*Cladosporium carpophilum* Thuem.) seems to be more serious on Belle than on Elberta. There seems to be little difference between dusting and spraying as to effective disease control. Calcium arsenate dusted on cotton in a young peach orchard caused serious injury to the young trees by burning the foliage.—*T. H. McHatton*.

650. MCCLINTOCK, J. A. Tomato wilt. Georgia Agric. Exp. Sta. Bull. 138. 12 p., 5 fig. 1920.—Tomato wilt (*Fusarium Lycopersici*), has discouraged the increase of tomato (*Lycopersicon esculentum*) acreage in Georgia. The fungus is widely spread in the Coastal regions and is becoming more so in the Piedmont section. The wilt generally attacks the plants when they are good sized and setting fruit, and is manifested by the yellowing and drooping of the leaves. Infected plants generally die within 10 days, but some remain alive until frost. Wilt resistant strains of tomatoes have been developed but these have not as yet proved safe and satisfactory. Investigations show that tomato wilt does not attack cotton, cowpeas, okra, and watermelons.—*T. H. McHatton*.

651. MAFFEI, LUIGI. La vaiolatura delle foglie dell' "Arachis hypogaea" Linn. dovuta a Cercospora. [Spotting of the foliage of *Arachis hypogaea* due to *Cercospora*.] Riv. Patol. Veg. 12: 7-11. 1922.—Dark chestnut-colored spots 1 cm. in diameter are caused on peanut leaves by a fungus that is named *Cercospora Arachidis* P. Henn. var. *macrospora* Maffei.—*F. M. Blodgett*.

652. MASSEY, L. M. Black-spot and mildew of roses. Amer. Rose Ann. 1922: 77-86. 1922.—Brief accounts of the life histories of *Diplocarpon Rosae* Wolf and *Sphaerotheca pannosa* (Wallr.) Lév. var. *Rosae* Wor. are given, together with recommendations for control.—L. M. Massey.

653. MEIER, FRED C., CHARLES DRECHSLER, and E. D. EDDY. Black rot of carrots caused by *Alternaria radicina* n. sp. Phytopathology 12: 157-166. Pl. 11, fig. 1-2. 1922.—A rather destructive storage rot of carrots (*Daucus carota* L.) has been found at various points in the eastern U. S. A. The rot seems to develop irrespective of the method of storage in pits, in mounds, or in cellars. It is characterized by a progressive softening and blackening of the tissues of the roots. Infection usually occurs at the crown and passes down through the root; but occasionally infection occurs at other points on the surface of the root. A fungus which proved to be a new species of *Alternaria* was isolated from the decaying tissue. When inoculated through wounds into healthy carrot roots, this fungus produced a rot identical in appearance with that from which it was originally isolated. Under very favorable conditions infection was also obtained on the leaves; but such leaf infection was never found in the field. Comparison of this fungus with *Macrosporium carotae* Ellis showed very marked differences in the size and form of the spores and also in the growth produced upon various media.—B. B. Higgins.

654. MONTEALEGRE, MARIANO R. Enfermedades del café. La maya o hilo blanco de las raíces. [Coffee diseases. White thread disease of the roots.] Bol. Camara Agric. Costa Rica 2: 193-201. 1922.—Coffee root disease has been serious in Costa Rica for many years. The fungi concerned have not been definitely determined. Carbon bisulphide and other treatments were found ineffective or so expensive as to be prohibitive. Lime-sulphur was finally tried and found effective when the solution was applied about the roots.—John A. Stevenson.

655. PEKLO, YAR. Na nové cesté. [On the new path.] Ochrana Rostlin 1: 7-9. 1921.—*Puccinia glumarum* is doing great damage to wheat. Ordinarily it reduces the crop by almost 20 per cent. In 1916 the reduction on the large estates was as high as 35 per cent, and on the peasant farms even 50 per cent. Breeding of resistant varieties is the only means of controlling this disease. It was found that the squarehead varieties are resistant but are too late for Czecho-slovakia. The author succeeded in isolating some varieties from the crosses between the domestic varieties and those from Svaler and Slovakia, which show more resistance to *P. glumarum*. A review of the literature on breeding of resistant varieties is given.—E. Baudyš.

656. PRITCHARD, F. J., and W. S. PORTE. Isaria rot of tomato fruits. Phytopathology 12: 167-172. Pl. 12, fig. 1. 1922.—A rot of tomato fruits, not previously described, has been found in the experimental grounds at Arlington, Virginia, and at Washington, D. C., during 1919, 1920, and 1921. This rot was produced by a fungus which is described as *Isaria clonostachyoides* n. sp. The fungus was grown upon various media and the chief characteristics of its growth recorded. Inoculations were made on both wounded and sound tomato fruits of various ages. Some infections were produced in all trials; but the percentage of infection was somewhat higher in wounded than in sound fruits. Very young and also ripe fruits were more readily infected and rotted faster than large green fruits. The fungus is not parasitic upon the leaves and stems of the tomato plant.—B. B. Higgins.

657. SALMON, E. S., and E. HORTON. Lime-sulphur and calcium caseinate as a fungicide. Jour. Ministry Agric. Great Britain 28: 995-999. 1922.—By tests conducted in the greenhouse it was determined that lime-sulphur at a strength of 1.003 sp. gr. (1 gallon of the concentrated solution (1.30 sp. gr.) to 99 parts of water), and containing 0.16 per cent of polysulphide sulphur, is lethal for the "powdery" conidial stage of the hop mildew (*Sphaerotheca Humuli* (DC.) Burr.) when the lime-sulphur is used with calcium caseinate in order to secure complete wetting of the fungus.—M. B. McKay.

658. SALMON, E. S., and H. WORMALD. Hop "canker" or "growing off." Jour. Ministry Agric. Great Britain 29: 354-359. 1 pl. 1922.—A disease of hops caused by *Fusoma parasiticum* is described in which typically 1 or more of the vines in a hill are killed by a cankering or eating away of the tissues at point of attachment to the rootstock. Generally the entire hill is not killed though cases have occurred where from 5 to 10 per cent of the hills in a garden have been completely killed.—Preventive measures listed are hard "cutting" or "dressing" of all hills in the affected part of the garden, grubbing up and destroying all dead hills, collecting and destroying all the cuttings from the hills in the affected part of the garden, and avoiding poor drainage.—M. B. McKay.

659. SMOLAK, YAR. Ochrana bramboru na poli. [Control of potato diseases in the field.] Ochrana Rostlin 1: 17-19. 1921.—Spraying with Bordeaux mixture is recommended for the control of diseases caused by *Phytophthora infestans* and *Alternaria Solani*, both of which are spread throughout the state.—E. Baudyš.

660. STRAŇÁK, FR. Fusariosa Žita. [Snow mold of cereals.] Ochrana Rostlin 1: 5-7. Fig. 1-2. 1921.—*Fusarium* may produce so much damage to cereals that it does not pay to harvest them. The development of the disease depends largely on weather conditions. It appears in epidemic form during certain summers and in certain regions. An account of the development of the pathogene is given. In experiments to control the disease fusariol and uspulum were mainly tested, the latter giving the better results.—E. Baudyš.

661. STRAŇÁK, FR. Rakovina bramboru. [Potato canker.] Ochrana Rostlin 1: 46-48. 1921.—The author gives the history of the appearance and world distribution of this disease. *Synchytrium endobioticum* was brought to Czecho-Slovakia from Germany in 1916. A description of the life history, symptoms, and damage done by the disease is given. In Czecho-Slovakia 91,434 hectares of soil are infected by the disease. Šluknovský County has been declared infected by the disease and is closed. In the infested soil, resistance of varieties is tested and it has been found that the most resistant varieties are Jubel, Roode Star I, Prefrent, Effect, Present, and Eigenheim.—E. Baudyš.

662. STUCKEY, H. P., and B. B. HIGGINS. Spraying peaches. Georgia Agric. Exp. Sta. Bull. 135. 91-101. 1919.—The following diseases, with means of control, are discussed: scab (*Cladosporium carpophilum*), brown rot (*Sclerotinia fructigena*), leaf curl (*Eriosea deformans*), and several insects, giving also spray formulas and applications.—T. H. McHatton.

663. TELLEZ, OLIVERIO. Una plaga en el estado de Jalisco. La "Pinta" o "Clavo" de la naranja y de la guayaba. [Anthracnose of orange and guava in Jalisco.] Rev. Agric. [Mexico] 6: 651-652. 2 fig. 1922.—*Gloeosporium Posidii* Delacr. causes anthracnose of the orange and guava. The use of Bordeaux mixture is recommended as a control measure.—John A. Stevenson.

664. TROST, JNO. F. Relation of the character of the endosperm to the susceptibility of dent corn to root rotting. U. S. Dept. Agric. Bull. 1062. 7 p., 2 pl. 1922.—Ears of seed corn of dent varieties characterized by starchy endosperm have been found to be infected with root-rot organisms more frequently than seed ears characterized by horny endosperm. In field tests the starchy seeds produce larger numbers of weaker plants which are more susceptible to root-rot.—J. T. Buchholz.

665. TROWBRIDGE, P. F. Report of the director, year ending June 30, 1921. North Dakota Agric. Exp. Sta. Bull. 159. 20-24. 1922.—Under "Biology," notes are given on black points of kernels, stem rust, scab, and "Helminthosporium blight," of wheat; on frost injury, wilt, and canker of flax; and on potato disease studies.—L. R. Waldron.

666. VIELWERTH, VL. O vlivu chemickýých mořidel na mazlavou sněť pšenickou. [The influence of treatment with chemicals on stinking smut of wheat.] Československý Zemědělec 2: 285-287. 1921.—Chemicals used in the control of the disease caused by *Tilletia Tritici* are divided into 3 groups, on the basis of whether they contain (1) copper, (2) formaldehyde, or (3) mercury. Copper sulphate does not kill the spores but only reduces their percentage of germination. Formalin and sublimate, on the other hand, kill the spores.—E. Baudyš.

667. WHITEHEAD, T. Varieties of swedes resistant to finger-and-toe. Jour. Ministry Agric. Great Britain 29: 362-368. 1922.—Two selections of Danish swedes resistant to the finger-and-toe disease (*Plasmidiophora Brassicae*) were tested in comparison with some British varieties susceptible to the disease. The results obtained seem to show that the 2 Danish varieties resist club-root to a marked degree and, in addition, keep better and have a higher feeding value than the remainder of the varieties included in the trial.—M. B. McKay.

668. YORK, HARLAN H., and WALTER H. SNELL. Experiments in the infection of *Pinus Strobus* with *Cronartium ribicola* (a preliminary statement). Phytopathology 12: 148-150. 1922.—Successful inoculations, under known conditions of temperature and humidity, on seedlings of *Pinus Strobus* with sporidia from the leaves of cultivated *Ribes nigrum* are reported. With an average temperature of 65°F. and a relative humidity of 94 per cent, sporidia developed on *Ribes* leaves in 5-6 hours, and infection of the pine needles occurred in 12½ hours after inoculation with the sporidia.—B. B. Higgins.

DISEASES CAUSED BY BACTERIA

669. DOOLITTLE, S. P. Comparative susceptibility of European and American varieties of cucumbers to bacterial wilt. Phytopathology 12: 143-146. 1922.—In comparable plantings of American and European varieties of pickling cucumbers it was found that all of the European varieties were much more susceptible to bacterial wilt than the American varieties.—B. B. Higgins.

670. GIROLA, CARLOS D. Agallas de corona del duraznero. [Crown gall of peach.] Bol. Ministerio Agric. Nación [Argentina] 26: 257-259. 1 pl. 1921.—Crown gall (*Bacterium tumefaciens* Erw. Sm. & Town.) of peach and its control are discussed.—John A. Stevenson.

671. LEE, H. A. Relation of the age of citrus tissues to the susceptibility to citrus canker. Philippine Jour. Sci. 20: 331-341. Pl. 1-4. 1922.—Experiments are presented in which fruits of *Citrus sinensis*, *C. nobilis* var. *unshiu* and *C. maxima* were inoculated at graduated stages in their maturity, from standard cultures of the citrus canker organism, *Pseudomonas Citri* Hasse. The experiments, carried over a length of 2 years, show that the period of serious susceptibility from a commercial point of view is 54 days or less for the unshiu oranges, 105 days or thereabouts for the Washington navel orange, and more than 135 days for the grapefruit varieties. The results show a very definite decrease in susceptibility of citrus tissues, both fruit and foliage, as they approach maturity. This is of very great importance in control work.—E. D. Merrill.

672. LEE, H. A., and A. SHINO. Citrus canker control experiments in Japan. Philippine Jour. Sci. 20: 121-151. Pl. 1-4, fig. 1. 1922.—Experimental work on the prevention of citrus canker upon the Washington navel variety of sweet orange, *Citrus sinensis*, is described. The following results were obtained by these methods: Copper sprays without other treatment reduced the number of fruits affected with citrus canker to as low as 34, 37, and 46 per cent. Untreated plots had percentages of cankered fruits of 80, 86, 92, and 96 per cent. The cost of these spray applications for the season was from 32.4 to 33.7 Japanese sen per tree. Lime-sulphur without other treatment reduced canker, but not to such an extent as did the copper sprays. The applications of this spray for the season cost 31 Japanese sen per tree. Formalin solution (1 to 100) did not reduce the canker. On the contrary, the trees sprayed with formalin had a very slightly larger percentage of cankered fruits than did the controls. The cost of

formalin sprays for the season was 1 Japanese yen per tree, or 3 times the cost of any of the other sprays. Spraying with copper sprays, accompanied by a removal of the sources of infection before the period of canker activity, reduced the canker percentage on treated plats to 9.25, 6.5, and 18.5 per cent. The cost of such treatments was 92 sen for Bordeaux 4-4-50 mixture, 90 sen for neutral Bordeaux mixture, and 92 sen for Burgundy 3-3-50 mixture.—Data are presented to show that wind prevention in itself may reduce citrus-canker development from 50 to 60 per cent to 6, 20, and 37 per cent. The injury by citrus canker to the Washington navel orange is described in detail. It seems reasonable to conclude that, in countries where citrus canker is already widespread or universal, a feasible control may be obtained upon citrus fruits of the general susceptibility of the Washington navel.—*E. D. Merrill.*

673. McLEAN, F. T., and H. A. LEE. Pressures required to cause stomatal infections with the citrus-canker organism. *Philippine Jour. Sci.* 20: 309-321. *Fig. 1-2.* 1922.—A method is outlined for applying measurable pressure to *Citrus* leaves and determining by this means the pressures necessary to cause penetration of such tissues by water. Tests of the injection pressures of *Citrus* leaves gave the following results: The average pressure for Pernambuco grapefruit was 19.5 cm. of mercury; seedling East Indian pummelo, 19.6; Washington navel orange, 20.8; and Szinkom mandarin orange, 33.6. The average injection pressures of the above 4 varieties are directly proportional to their canker resistance, as shown by field observations. Leaves of Szinkom mandarin orange, a resistant variety of *Citrus*, and seedling grapefruit and pummelo trees, both very susceptible, were tested for their resistance to the entrance of canker organisms applied in water under pressure. Szinkom mandarin orange leaves were resistant to canker infection by immersion, and up to pressures of 10 cm. of the mercury column. With high pressures numerous cankers developed in leaves of this variety. Grapefruit and pummelo leaves developed canker readily by immersion without added pressure. The pressures necessary to cause canker infection were thus in agreement with the degree of observed field resistance of the sorts tested. The results obtained strongly substantiate the theory previously advanced that structural differences in the stomata constitute one cause for the differences in susceptibility of the mandarin orange and the grapefruit and pummelo varieties. In the mandarin orange apparently the structure of the stomata prevents the ingress of surface water; in the grapefruit the stomatal structure is such as to allow the ingress of surface water which thus affords a medium of entrance for the canker bacteria. The results definitely indicate that the resistance of the mandarin orange is due to mechanical structural differences.—*E. D. Merrill.*

674. PAINE, SYDNEY G., and MARGARET S. LACEY. Chocolate spot disease or streak disease of broad beans. *Jour. Ministry Agric. Great Britain* 29: 175-177. 1 *pl.* 1922.—The chocolate spot or streak disease of broad beans caused by *Bacillus Lathyri* occurred as a serious epidemic in many counties and was very general throughout a large part of England and Wales in 1920. The apparent spread of the disease seemed to suggest wind dispersal of the causative organism. The causal organism is carried on the seed of winter beans, and especially on those bored by the bean beetle, *Bruchus rufimanus*. In its attacks on the young pod this beetle may inoculate the plant at the time of egg-laying and the young larvae may infect the seed when they bore their way in.—Measures of control suggested are to dress the land well with potash, reject seed showing an excessive amount of boring by beetles, and sterilize the seed by soaking for 10 minutes in weak lysol or formalin or by dressing with one of the tar preparations supplied for the purpose.—*M. B. McKay.*

675. WELLES, COLIN G., and EMILIANO F. ROLDAN. Solanaceous wilt in the Philippine Islands. *Philippine Agric.* 10: 393-398. *Pl. 1-3.* 1922.—The authors report studies on *Bacterium Solanacearum* E. F. Smith which is known to cause serious disease of tomato, tobacco, and egg-plant in the Philippines. Egg-plants appear somewhat resistant and may be grown successfully if planted during the rainy season so that maturity will be reached early in December. A description of the disease on tomato, tobacco, egg-plant, and castor bean is given. *Chrysanthemum coronarium* is attacked by a similar, if not identical, organism.—*Sam F. Trelease.*

DISEASES CAUSED BY ANIMAL PARASITES (INSECTS, NEMAS, PROTOZOANS, ETC.)

676. EYER, JOHN R. Notes on the etiology and specificity of the potato tip burn produced by *Empoasca mali* LeBaron. *Phytopathology* 12: 181-184. *Pl. 14, fig. 1.* 1922.—Continuing a study of the demonstrated relation of the potato leafhopper (*Empoasca mali* Le B.) to a certain form of the tip burn of potato (*Solanum tuberosum* L.) leaves, an attempt has been made to determine the nature and the transmissibility of the substance injected into the leaves by the leafhopper. Inocula were prepared by macerating either nymphs or the adult leafhoppers in sterile water or in 10-70 per cent alcohol. This extract was injected, with a small hypodermic needle, into the midrib of growing potato leaves. Into other leaves similar quantities of water or alcohol were injected to serve as checks. The leaves inoculated with leafhopper extract developed typical tip burn, while the checks remained healthy. The extract from nymphs was more virulent than that from adult insects. Extracts prepared from other species of sucking insects failed to produce tip burn. Direct sunlight was not necessary for the development of tip burn, though heavy shade retarded the development of the disease.—*B. B. Higgins.*

677. GOODEY, T. On the susceptibility of clover and some other legumes to stem-disease caused by the eelworm, *Tylenchus dipsaci*, syn. *Devastatix*, Kühn. *Jour. Agric. Sci.* 12: 20-30. *Pl. 1, fig. 1-2.* 1922.—After a brief review of the literature, the parasite and the disease are described. The term stem-disease corresponds to the German term *Stockkrankheit* and should be retained although the name stem-rot applied to the disease caused by *Sclerotinia Trifoliorum* may be somewhat confusing. Symptoms of the 2 diseases are compared. Preliminary inoculation with single eggs containing well developed larvae showed that mature and sexually differentiated worms are developed in 24-30 days after inoculation. Other experiments showed that red clover is very susceptible to attack. For the main experiments, seed of 4 varieties of red clover, 2 of cow grass, 2 of alsike clover, and 5 of white clover were sown in pots in heavily infested soil. Seed of kidney vetch, sainfoin, lucerne (Provence), and trefoil were also used. After 37 days all seedlings were harvested and healthy and diseased plants preserved separately. Data were secured from this material on the percentage of infection, and by means of counts from infected plants an idea of the intensity of infection was obtained. The plants used were found to be separable into 4 groups: group 1, including the red clovers, Swedish cow grass, and kidney vetch, was very susceptible; group 2, including English cow grass and 2 varieties of alsike, was very much less susceptible; group 3, including sainfoin and 3 varieties of white clover, was only slightly susceptible; and group 4, including lucerne, trefoil, and Sutton's Mammoth white clover, was entirely resistant. Canadian red clover was found to be much more susceptible than other species of red clover. The author concludes that to avoid stem-disease it is advisable not to sow red clover, cow-grass, or Alsike clover, but rather trefoil, lucerne, or a large white clover.—*V. H. Young.*

678. WEISS, H. B., and E. WEST. Notes on the dodder gall weevil, *Smicronyx sculpticollis* Casey. *Ohio Jour. Sci.* 22: 63-65. *1 fig.* 1921.—Galls on *Cuscuta Cephalanthi* Eng. produced by the weevil are described.—*H. D. Hooker, Jr.*

INFECTIOUS CHLOROSES (MOSAIC AND PEACH YELLOWS GROUPS, ETC.)

679. ANONYMOUS. Mosaic disease-susceptible and immune varieties. *Jour. Jamaica Agric. Soc.* 25: 427-429. 1921.—This is a discussion of cane varieties immune and susceptible to the mosaic disease, based on work carried out in Porto Rico with the variety Kavangire.—*John A. Stevenson.*

680. ARTSCHWAGER, E. Occurrence of phloem necrosis in leafroll tubers. *Phytopathology* 12: 193-194. 1922.—Potato (*Solanum tuberosum* L.) plants of long leafroll lineage have been observed to produce tubers and stolons which show severe phloem necrosis. When tubers showing only slight symptoms of necrosis were planted the necrotic tissue increased as the tubers began to sprout. It developed near the eyes from which sprouts were growing irre-

spective of the position of the eye on the tuber, showing that necrosis is linked with growth activity.—*B. B. Higgins.*

681. BARRUS, MORTIER F., and CHARLES C. CHUPP. **Yellow dwarf of potatoes.** *Phytopathology* 12: 123-132. *Pl.* 7-8, *fig.* 1. 1922.—A disease of Irish potatoes (*Solanum tuberosum*), thought to be new to science, has recently been recognized in several counties of New York State. The leaves of the diseased plants have a yellow color, and toward the tops of the plants the leaflets show a tendency to roll. The stems are stocky but decidedly dwarfed. When sectioned they show numerous brown specks in the cortical tissue, especially in the upper nodes. Such plants produce a few irregular tubers which are usually cracked. When sectioned the tubers also show the brown specks in the cortical tissues. The disease is apparently transmitted through the soil and also by some agency above the soil, but the cause of the disease and the exact method of its transmission have not been determined.—*B. B. Higgins.*

682. COOK, MEL. T. **The dissemination of peach yellows and little peach.** *Phytopathology* 12: 140-142. 1922.—It has been found that peach yellows and little peach may be transmitted to healthy trees by inserting a bud from a diseased tree, even though the bud may fail to grow. They may be transmitted also by inserting a piece of bark from a diseased tree; but attempts to infect healthy trees by injecting juice from diseased trees have failed. The length of the incubation period may be 1-4 years, depending upon the severity of the disease in the tree from which the bud was taken. A bud taken from an inoculated tree during the incubation period may transmit the disease. Trees from which buds are to be taken for nursery work should have been under previous observation for at least 4 years.—*B. B. Higgins.*

683. COTTON, A. D. **Potato leaf curl demonstrations.** *Jour. Ministry Agric. Great Britain* 28: 1019-1021. 1922.—Comparative demonstrations of the cropping qualities of healthy and leaf-curl or leaf-roll diseased seed potatoes were conducted in 1921 in 10 widely separated localities. The healthy seed came from a field free from disease. A 2nd lot of seed was from a field a few miles distant which was generally, though slightly, affected with leaf curl. The seed affected with leaf curl yielded on the average only about $\frac{1}{2}$ as much as healthy seed.—*M. B. McKay.*

684. FAWCETT, GEO. L. **Las primer as investigaciones sobre el mosaico en Java.** [The first investigations on mosaic in Java.] *Rev. Indust. Agric. Tucumán* 11: 121-123. 1920.—The author reviews the work of Kobus and Wilbrink-Ledeboer who first studied the mosaic disease of sugar cane in Java. The author's experiments confirm their conclusion that plants grown from true seed obtained from diseased plants are free from the disease. Their idea that the disease is merely a vegetative variation has of course been definitely disproved.—*John A. Stevenson.*

685. FAWCETT, GEO. L. **Notas sobre la extirpación del mosaico de la caña.** [Notes on the eradication of the cane mosaic.] *Rev. Indust. Agric. Tucumán* 11: 74-76. *Fig.* 1-2. 1920.—The author divides sugar cane varieties into 3 classes with respect to their behavior toward the mosaic disease: (1) immune varieties, represented by Kavangire; (2) resistant varieties, including a number of the Javan seedlings; (3) susceptible varieties. The native varieties of Tucumán fall in the last class although some are superior to the resistant types in sucrose and lack of fiber. In the experimental plots of the experiment station an attempt was made to combat the disease by roguing out all diseased stools. Although these plots were isolated from other cane nearly all stools showed the disease. Apparently there is no hope for the susceptible varieties.—*John A. Stevenson.*

686. HUNGERFORD, CHAS. W. **Leaf roll, mosaic and certain other related diseases in Idaho.** *Phytopathology* 12: 133-139. *Pl.* 9. 1922.—In Idaho both leaf roll and mosaic have gradually increased in severity and extent since first noted in 1919. Comparable plantings of potatoes from healthy and from diseased plants have shown that these diseases may cause

heavy loss in yield.—In "Russett dwarf," similar to certain types of mosaic, the diseased plants are much dwarfed and from a distance their yellowed leaves present a very rusty appearance. In more advanced stages the leaves drop off, beginning at the bottom of the plant. Dark brown streaks appear on the leaf petioles and on the lower part of the stems. The yield is reduced $\frac{1}{2}$ – $\frac{3}{4}$. The disease is infectious and is transmitted as is mosaic.—A condition known locally as "Calico" seems to be inherited but is not infectious and is not considered a serious malady.—*B. B. Higgins.*

687. PERRET, CL. Sur les maladies des pommes de terre. [Potato diseases.] Ann. Épiphyties 7: 304–314. 1921.—Germination of tubers on trays shows up spindle sprout ("filosite") but not phloem necrosis or mosaic. A nitrogenous fertilizer does not cure phloem necrosis and mosaic but it masks the symptoms. Experiments have demonstrated the prominent rôle played by sound tubers in potato production. The effect of nitrogenous fertilizers on the vegetative growth of the Andrea variety was very clear; that of a radio-active fertilizer was very slight but the crop was increased. Under the action of extra intensive manuring the plants grew luxuriantly. Nevertheless, leaf roll symptoms were visible at the end of the season on the Andrea variety, the yellow mosaic spots were very apparent on the Violette du Forez, and the number of dwarf plants with seed tubers preserved was considerable. The variety Violette du Forez which has existed in the province of the Loire for over 50 years has slowly lost a part of its characteristic stability, and the process of decline has been rather definite. The incurvation of the leaves does not occur, but one sees in the field numerous missing plants, a backward crop, and many dwarf plants with seed tubers preserved; also, plants with a single stem only, with the yellow spots on the leaves and with here and there some signs of leaf curling. This trouble is probably a leaf roll or mosaic degeneration. At altitudes of 850–1100 m. the regularity of the fields is greater than in the lower regions (650–850 m.). The method of keeping potatoes appears to exercise a certain influence on the process of degeneration.—In the varieties affected with phloem necrosis the author has followed the progress of the degeneration during the years 1918–1920. A table shows very clearly the progress of the leaf roll and the favorable effect of good meteorological conditions on the yields.—The important symptoms of phloem necrosis which accompany the considerable reduction in yield are as follows: (1) Incurving of the leaves appearing early and at the lower part of the plant. (2) Incurvations later becoming general in nearly all of the leaves. (3) Agglomerations of tubers at the base of the stalk. (4) Preservation of the seed tuber in the ground, even in moist seasons, in at least 30 per cent of cases. The preservation of the seed tuber is observed also in the varieties with mosaic, and in dwarf plants. The decline of strains of potatoes assumes 3 main forms in the Loire: (a) The phloem necrosis form, frequent in the varieties Institut de Beauvais, Merveille d'amérique, and Bimel. (b) The form associated with mosaic and missing plants, the type which has been chiefly included under mosaic without definite correlation with spindling sprout ("filosite") and which has been observed in Violette de Paris and Saucisse de Paris. (c) Mixed forms participating in the 2 preceding; there may be the leaf roll symptoms, dwarf stalks, and sometimes missing plants, as observed in Anglaise, and Fin de Siècle. Preservation of the seed tubers in the ground occurs in these 3 forms. The size of the crop and percentage of dry matter are diminished and the content in nitrogenous material is increased in the tubers.—*Phytophthora infestans* is not to be considered as a cause of degeneration.—The progeny of a plant with phloem necrosis shows leaf roll symptoms. A plant appearing healthy, but growing among other plants with leaf roll, may produce either sound or leaf roll progeny. There are no immune plants; those appearing immune are only accidentally non-infected. Growing of seed potatoes in other localities exercises a beneficial action on the yields and has a rejuvenating effect on the variety; but such methods do not eradicate mosaic, leaf roll, or spindling sprout ("filosite").—The author considers the measures necessary to protect French strains from degeneration diseases.—*E. Fœx.*

688. POOLE, R. F. Celery mosaic. Phytopathology 12: 151–154. Pl. 10, fig. 1. 1922.—During the season of 1921 a stunted and malformed condition of celery (*Apium graveolens*) was noted in 2 localities of New Jersey. This condition was found to be due to an infectious

mosaic which could be transferred from diseased to healthy plants by means of aphids (*Myzus persicae*). There were some indications that the celery plants became infected from mosaic in nearby tomato plants.—*B. B. Higgins*.

NON-PARASITIC DISEASES

689. ADAMS, J. F. Observations on frost protection and drought spot of apple. *Phytopathology* 12: 184-187. *Fig. 1.* 1922.—During the spring of 1921 late frost so injured the apple crop in Delaware that the yield for the state was reduced to 12 per cent of normal. However, 1 orchard was noted in which a normal yield was produced. Inquiry brought out the fact that some charcoal furnaces on the windward side of this orchard produced a smudge that undoubtedly protected the fruit from frost. During the summer the York Imperial apples in this orchard showed considerable drought spot. Counts made Aug. 1 showed 5 per cent injury; but a month later the more seriously affected fruits had dropped so that counts at that time showed only about 1 per cent of diseased fruit. A long dry spell during early summer together with unfavorable soil conditions apparently brought on the disease.—*B. B. Higgins*.

690. FIROR, J. W. Winter killing of fruit and nut trees. *Georgia State Coll. Agric. Circ.* 60. 4 p., 1 fig. 1920.—This reprint contains a general discussion of winter injury on fruit trees in Georgia with suggestions concerning maturing of trees before frost, mounding in late fall, and using whitewash and cover crops for protection.—*T. H. McHatton*.

691. GLEISBERG, W. Hagelschäden bei Bohnen-Keimpflanzen. [Injury to bean seedlings by hail.] *Illustr. Landw. Zeitg.* 42: 184-185. *Fig. 1-2.* 1922.—By experiment it is shown that bean seedlings may be deprived of various important organs such as the cotyledons or the plumule and still bear as good crops as normal plants. The details attending the recovery of the plants are given.—*John W. Roberts*.

692. LINSBAUER, L. Ueber eine Stoffwechselerkrankung an Apfelfrüchten und deren Heilung. [A physiological disease of apple fruits, and its cure.] *Zeitschr. Pflanzenkr.* 32: 1-17. 1922.—The author describes a peculiar malformation of apples of the variety Edelrot from the Southern Tyrol. The typical fruit of this variety averages 60-65 mm. by 60-64 mm., and the weight varies between 110 and 114 gm. Larger specimens are very regularly spherical-oblong; smaller specimens are blunt cone-shaped towards the stem end. Around the stem itself the fruits are flattened. The curve of the surface is uniform, tapering toward the calyx end. The skin is finely glossy and light greenish-yellow, later becoming yellowish-white like wax.—The fruits from affected trees are on the average smaller and inferior in shape. The average weight of an abnormal apple was 42 gm. as compared with 106 gm. for the normal fruit. Affected apples often appear laterally undeveloped toward the calyx end, becoming more pointed than typical ones. The skin of the diseased fruit shows, usually toward the calyx end, shiny, chestnut-brown, sharply defined areas which become confluent and in consequence of which there is a one-sided growth. At times the smaller fruits are covered by a brown, scabby crust with cracks, which no doubt contributes to the deficiency of sap within the fruits.—With the exception of the fruits, affected trees appear normal. The trees are well cared for, especially as regards spraying, etc. The soil is a sandy loam 40-80 cm. in depth underlain by "Bach schotter" (gravel?), and is described as very good. Every 8-14 days the trees are watered. In consequence of early applications of night-soil the trees have made a luxuriant growth, and the owner is inclined to attribute to this manuring process the development of the malformed fruit.—Apparently the most vigorous trees suffered most, while weak trees never developed the trouble.—The author determined the losses due to transpiration during a 24-hour period and found that the loss from transpiration was less in normal than in abnormal fruits. Transpiration, however, was greater in the larger specimens of both normal and abnormal fruits. Chemical analysis revealed a higher water content in the sound fruits, together with a corresponding decrease in dry substance. The sound fruits were higher in nitrogen compounds. The disease in some instances caused a 50 per cent loss in the crop.—

Unfavorable composition of the mineral nutrients available to the trees is suggested as possibly responsible for this malformation of the fruits. Fertilizer experiments conducted on hay in the affected orchards showed beneficial results from acid phosphate, which gave almost double the return.—Experiments were now tried to test the effect of suitable fertilizers on the development of the fruits. Fifteen affected trees were divided into 3 plots. The 1st received no treatment (check); the 2nd, potash and lime; the 3rd, basic slag and 18 per cent superphosphate. At the end of the experiment the trees in plot 1 were freely affected. The potash and lime plot showed no change for the better. The trees receiving acid phosphate, however, showed a remarkable improvement, and in the bearing trees no sign of the trouble was noted. In the abnormal fruits the nitrogen content sinks to a minimum, but this content becomes increased after the potash-lime application. In the fruits from trees treated with phosphoric acid, however, the nitrogen content was equal to that of the normal fruits.—The conspicuous effect of phosphoric acid may be regarded as a fact, but this does not explain the remarkable results. It would seem premature to attribute to the phosphoric acid a specific rôle in the development of the fruit. That the phosphoric acid in the soil had diminished owing to the practice of overfertilizing with nitrogen for many years is apparent from the experiments with the orchard hay. It is argued that the supply of phosphoric acid has increased the capacity of the trees to make use of potash. Apparently it has really been the potash to which should be credited the normal development of the fruits. The author states that further careful experiments and analyses would no doubt throw considerable additional light on the subject.—*H. T. Güssow.*

DISEASES OF UNKNOWN CAUSE

693. BROWN, J. G., and FREDERICK GIBSON. Some observations on alfalfa girdle. *Phytopathology* 12: 188-190. *Pl. 15.* 1922.—A serious disease of alfalfa (*Medicago sativa* L.) known as "Girdle" has been under observation in the southwestern part of the U. S. A. since 1912, but the cause of the malady has never been determined. Recently, similar girdles have been observed on several other species of plants in this region. In 1 case a scale insect (*Coccus hesperidum* L.) was found associated with the girdle. It seems probable that the scale is connected with the disease as a carrier of the causal organism, or otherwise.—*B. B. Higgins.*

694. CHANDLER, S. E. The brown bast disease of the Para rubber-tree. *Nature* 109: 357-360. 1922.—A review of 6 recent publications is made.—*O. A. Stevens.*

695. FAWCETT, GEO. L. Notas preliminares sobre una enfermedad del tabaco. [Preliminary notes on a tobacco disease.] *Rev. Indust. Agric. Tucuman* 12: 5-17. *Fig. 1-14.* 1921.—The most serious disease of tobacco in Tucuman province of Argentina is that known as "Corcova," a term descriptive of the form taken by diseased plants. Black lines somewhat resembling insect galleries develop on both surfaces of the leaves and on the stems; these areas may coalesce. Affected portions of leaves become yellow in color, and finally wither and droop. Partial recovery is sometimes noted during periods of dry weather. The continued growth of unaffected portions of leaves causes a characteristic curling or distortion. Insects are not responsible nor has it been possible to connect fungi with the disease as causative agents. Bacteria found in connection with the lesions of advanced cases failed to reproduce the disease. Certain varieties (Turco and Criollo in particular) are less subject to the disease than others. Early plantings show less of the disease than late plantings. Spraying with Bordeaux or sulphur compounds gave uniformly negative results.—*John A. Stevenson.*

696. GIRARDI, J. Durazneros. Manchas en las frutas. [Fruit spot of peach.] *Defensa Agric. [Uruguay]* 3: 55-56. 1922.—A fruit rot and leaf spot (cause not determined) has attacked peaches. Control measures are suggested.—*John A. Stevenson.*

GENERAL AND MISCELLANEOUS PATHOLOGICAL LITERATURE

697. BAUDYŠ, E. Význam ochrany rostlin pro zemědělství. [Importance of plant disease control for agriculture.] *Ochrana Rostlin* 1: 3-5. 1921.—Crop production is now $\frac{1}{3}$ - $\frac{2}{3}$ of

that before the war. The reasons for this state of affairs are the lack of some of the mineral nutrients, mainly calcium, phosphorus, and potassium, and the inferior human force. Lack of mineral nutrients favors the spread of some diseases. The unusual spread of rust (*Puccinia graminis*) is attributed to the lack of calcium and phosphorus.—The most destructive disease of cereals is that caused by *Fusarium nivale*. Detailed estimates show that this disease causes damage to the extent of about 40 per cent. It can be controlled by sublimate, uspulum, or by breeding resistant varieties. The author observed that not all varieties are equally susceptible to this disease. Take-all disease, caused by *Ophiobolus* and *Leptosphaeria herpotrichoides*, was scarcely known before the war; now it reduces the crop by about 5–10 per cent. The spread of this disease is attributed to late plowing of the stubble field. *Helminthosporium* may reduce the crop of oats and barley by about 30 per cent. Smut reduces the crop of wheat and of oats each by about 10 per cent. Corn smut reduces that crop by 15 per cent. About 10 per cent of the potato crop is destroyed by black leg, and the damage done by all potato diseases is about 30 per cent. The conclusion is drawn from these data that disease control is very important for agriculture.—*E. Baudyš*.

698. BRAUN, HARRY. Effect of delayed planting on germination of seed wheat treated with formalin. *Phytopathology* 12: 173–180. *Pl. 13, fig. 1–3*. 1922.—A comparison of the injury produced by the ordinary formalin treatment and by the pre-soak formalin treatment was made with 5 varieties of wheat. One set of a quart of each variety was dipped for 30 minutes in a solution of 1 part formaldehyde to 320 parts water, drained, and covered for 1 hour. Another set was treated in the same way except that the seed were dipped 10 minutes in water, drained, and covered 5½ hours before dipping into the formalin solution. All were then spread out to dry. At the end of 24 hours and again at the end of a week 300 seed were counted from each lot and planted in pots in the greenhouse along with a similar lot of untreated seed. There was some injury to the seed treated by the ordinary formalin method and the injury increased in most cases when the seed were held for 1 week. With seed treated by the pre-soak method there was no injury. In most cases there was an increase in the per cent of germination and a marked stimulation of growth.—*B. B. Higgins*.

699. BROWNING, C. H., J. B. COHEN, and R. GULBRANSEN. The antiseptic properties of cyanine dyes. *British Med. Jour.* 3196. 514–515. 1922.—The results of recent tests on the cyanine group of dyes concerning their antiseptic properties show: (1) certain of the cyanine dyes are extremely potent antiseptics—for example, sensitol red for staphylococci in watery medium; (2) selective antiseptic action as between staphylococcus and *B. coli* is exhibited to a higher degree by certain of these dyes—for example, sensitol red—than by any other compound hitherto investigated, the ratios of the sterilizing concentrations probably being greater than 2,000 to 1 (with crystal violet the ratio is 500 to 1); and (3) sensitol green is the most active of these dyes both in serum and watery medium for *B. coli*. Also, in the case of *B. coli* the antiseptic action in serum is more intense than in water medium.—[*Through Public Health Engineering Abstracts*.]

700. CHASE, W. W. The principal parasites of the peach. *Georgia State Bd. Entomol. Bull.* 57. 46 p., 10 pl. 1920.—Besides a discussion of several insects life histories are given and methods of control for brown rot (*Sclerotinia fructigena* Schroet.), crown gall (*Pseudomonas tumefaciens*, E. F. S. & Town.), peach scab (*Cladosporium carpophilum*), peach leaf curl (*Exoascus deformans* (B) Fuckel). The bulletin concludes with a discussion of concentrated lime-sulphur and the management of peach orchards.—*T. H. McHatton*.

701. DIX, WALTER. Beizapparate. [Apparatus for the treatment of seed.] *Illus. Landw. Zeitg.* 42: 84–86. *Fig. 93–96*. 1922.—Detailed descriptions, with drawings, are given of elaborate apparatus for use in the fungicidal treatment of seed grains.—*John W. Roberts*.

702. GIROLA, CARLOS D. Sobre algunas enfermedades de la papa. [Concerning some potato diseases.] *Bol. Ministerio Agric. Nación [Argentina]* 26: 260–264. 2 fig. 1921.—Brief descriptions are given of rosette (*Corticium vagum* B. & Curt. var. *Solani* Burt.) and scab (*Actinomyces scabies* Thaxter). Control measures are outlined.—*John A. Stevenson*.

703. LEK, H. A. A., VAN DER. Over den invloed van enting en bastaardeering op de vatbaarheid voor parasitaire aantastingen. [The influence of grafting and hybridisation on the susceptibility to diseases.] *Tijdschr. Plantenz.* 27: 124-128. 1921; 28: 1-14, 37-45, 97-103. 1922.—The writer points out first the difference between grafting and hybridisation; that in the 2nd case a new set of characters is being formed while in the 1st the existing characters are only modified more or less through the surrounding environment. After giving numerous examples of such modifications and of the relation between the stock and scion he points out the influence of the understem on the longevity of the grafted trees; that this is greatly decreased and that the period of degeneration and decline in vigor, during which the plants become susceptible to diseases, comes much earlier than in the case of ungrafted trees. In some cases the modifications brought about through grafting may be a thickening of the cuticle and changing of the hairiness; in other cases the chemical composition of both the plants (components) is materially changed. All this can influence the resistance of the plants to diseases. The nature of immunity of plants to diseases is also briefly discussed and the importance of the changes in the periodicity of plants as affecting their resistance to diseases is pointed out. The question of chimeras is then discussed and the somewhat unsatisfactory results obtained with plant chimeras in connection with obtaining disease resistant varieties are treated. The latter fail to throw any light on the possible changes in the physiological properties of the plants through the mutual influence of the components, as has been noticed on grafted plants, which may play some rôle in increasing the resistance to diseases, be this real or only apparent. The writer shows through numerous examples that the stem and the scion do not change each other's resistance to diseases and emphasizes the importance of selection of stocks resistant to root diseases and insects, which he thinks will play a considerable rôle in the propagation of cultivated woody plants.—*D. Atanasoff.*

704. McHATTON, T. H., and J. W. FIROR. Spray calendar for Georgia. Georgia State Coll. Agric. Bull. 220. 1½ p., 3 fig. 1920.—Spray schedules and formulas for fruits and vegetables are given.—*T. H. McHatton.*

705. MONTEMARTINI, LUIGI. L'applicazione degli articoli 6 e 7 della Convenzione internazionale di Roma 4 marzo 1914 contro le malattie delle piante. [The application of articles 6 and 7 of the international convention of Rome, March 4, 1914, against the diseases of plants.] *Riv. Patol. Veg.* 12: 1-6. 1922.—The difficulties of an effective inspection at ports of entry are discussed together with the need of a better and more complete organization of internal plant inspection service.—*F. M. Blodgett.*

706. MOREL, A., et A. ROCHAIX. Action microbicide par contact de quelques essences végétales à l'état liquide. [Bactericidal action of certain plant essences in liquid state.] *Compt. Rend. Soc. Biol.* 86: 933-934. 1922.—The essences of thyme, citron, juniper, and mint were found to possess bactericidal action on meningococci, staphylococci, diphtheria bacilli, and Eberth's bacillus.—*S. Morgulis.*

707. REINKING, OTTO A. Citrus diseases of the Philippines, Southern China, Indo-China, and Siam. *Philippine Agric.* 9: 121-179. Pl. 1-14. 1921.—The paper is divided into 6 sections, 1 for each region, 1 for control measures, and a summary compiled on the basis of the hosts. A description of the diseases, a discussion of the causal organisms, and suggestions regarding control measures are given. The study was made in collaboration with the U. S. Bureau of Plant Industry, and involved considerations of importance in connection with shipments of citrus varieties to the U. S. A. The following list gives the organisms associated with Citrus, many of these organisms being pathogenic: *Aleurocanthus citripertus* Q. & B., *Aschersonia aleyrodis* Webb., *A. sclerotioides* P. Henn., *Aspidiotus cocotiphagus* Marlatt, *Auricularia polytricha* Sacc., *Chrysomphalus aurantii* Mask., *C. aonidium* L., *C. dictyospermi* Morg., *Cladosporium Citri* Masee, *C. herbarum* (Pers.) Link, *Coccus hesperidum* L., *C. mangiferae* Green, *C. viridis* Green, *Colletotrichum gloeosporioides* Penzig., *Corticium salmonicolor* B. & Br., *Crinipellis galeatus* Pat., *Cyathus Montagnei* Tul., *Cystospora aberrans* Sacc.,

Daldinia concentrica Cas. & de Not., *Diaporthe citrincola* Rehm, *Diplodia Aurantii* Catt., *Dolichoderus*, *Duportella tristiuscula* Pat., *Eutypa heteracantha* Sacc., *Eutypella citricola* Speg., *Fiorinia theae* Green, *Fomes applanatus* Pers., *Ganoderma australe* Pat., *Gloeosporium intermedium* Sacc., *Heterochaete tenuicula* Pat., *Hypoxyton atropurpureum* Fr., *H. serpens* (Pers.) Fr., *Lepido saphes beckii* Newm., *L. gloverii* Pack., *Loranthus ferrugineus* Roxb., *L. parasiticus* (L.) Merr., *L. pentandrus* L., *L. philippensis* Cham. & Schlecht, *Massarina raimundoi* Rehm, *Meliola citricola* Syd., *Microcera coccophila* Desm., *Mucor*, *Myriangium duriae* Mont., *Nectria episphaeria* (Tode.) Fr., *Nummularia citrincola* Rehm, *Oecaphylla smaragdina* Far., *Ozonium auricornum* Lk., *Parlatoria brasiliensis* n. sp. Ms., *P. pergandii* Comst., *P. proteus* Curt., *P. ziziphus* Lucas, *Penicillium*, *Peroneutypa heterocantha* Sacc., *Pheidalogeton*, *Phoma*, *Phyllocnistis citrella* Stainton, *Phyllosticta circumsepta* Sacc., *Phytophthora*, *Polyporus caryophylla* Racib., *P. hirsutus* Fr., *P. Rickii* Pat. var. *philippinensis* Pat., *Polystictus flavus* Jungh., *Pseudoauidia trilobiformis* Green, *Pseudomonas Citri* Hasse, *Pulvinaria*, *Rhizoctonia*, *Rhytidopeziza rufula* Bres., *Saissetia*, *Schizophyllum commune* Fr., *Sclerotium*, *Septobasidium albidum* Pat., *S. carbonaceum* Pat., *S. leucostemum* Pat., *S. Reinkingii* Pat., *Termes*, *Traversoa dothiorelloides* Sacc. & Syd., *Trybliidiella mindanaensis* P. Henn., *Ulsaria Citri* Rehm, *Xylaria castorla* Berk., *Zignoella nobilis* Rehm.—S. F. Trelease.

708. REINKING, OTTO A. Notes on diseases of economic plants in Indo-China and Siam. Philippine Agric. 9: 181-183. 1921.—A host index is given of 50 diseases for plants other than citrus. The following are listed among the pathogens: *Aithaloderma claratisporum* Syd., *Cercospora batatae* Zimm., *Cercospora Henningsii* Allesch., *C. Nicotianae* Ell. & Ev., *C. vaginae* Kr., *Cercosporina ricinella* (Sacc. & Berl.) Speg., *Dictyothyriella mucosa* Syd., *Hemileia vastatrix* B. & Br., *Macrophoma Musae* (Cke.) Berl. & Vogl., *Meliola mangifera* Earle, *Mycosphaerella gossypina* (Cke.) Atk., *Pestalozzia palmarum* Cke. & Grev., *Phytophthora faberi* Maubl., *Pseudoperonopora cubensis* (B. & C.) Rost., *Puccinia longicornis* Pat. & Hor., *Sclerospora*, *Sclerotium*, *Uredo Fici* Cast.—Sam F. Trelease.

709. ROSAM, V. O ochraně porostu proti chorobám a škudcům. [Control of plant diseases and insects.] Ochrana Rostlin 1: 2-3. 1921.—The author discusses the importance of control of plant diseases and insects for agriculture. The damage done by the plant diseases is greater than that done by the animal parasites. The present organization of phytopathological work is not sufficient. The suggestion is made to provide a law on the control of plant diseases, to organize work in the control, and to establish phytopathological stations. The propaganda should be conducted by means of leaflets, lectures, practical demonstrations, and moving pictures. Money could be obtained by taxing seed producers and plant breeders.—E. Baudyš.

710. SCHOEVERS, T. A. C. Ziekten en beschadigingen van tomaten. [Diseases and injuries of tomatoes.] Tijdschr. Plantenz. 28: 67-93. Pl. 1-4. 1922. [Also in Verslag. en Mededeel. Plantenziektenk. Dienst Wagenigen 26. 26 p. 1922.]—The following diseases and injuries of the tomato plant observed in Holland and remedies against them are briefly described: wire worm, *Oniscus*, *Verticillium albo-atrum*, *Rhizoctonia*, canker (*Diplodina* (*Didymella*) *Lycopersici*), *Sclerotinia libertiana*, fasciation, leaf-roll, soil sickness, *Heterodera radicola*, stripe disease (*Bacillus Lathyri*), *Cladosporium fulvum*, *Phytophthora infestans*, sunburn, mosaic, curl, hollow stem, *Aleurodes vaporariorum*, *Tetranychus*, aphids, blossom end-rot (*Phytobacter Lycopersicum*), uneven ripening, fruit splitting, hollow fruit. General measures for avoiding tomato diseases are discussed and 2 keys are given for the determination of the above named diseases.—D. Atanasoff.

711. STRANG, R. B. Diseases of the swede crop in Cumberland and Westmorland in 1921. Jour. Ministry Agric. Great Britain 28: 1093-1096. 1922.—Damage to swedes from 4 diseases, powdery mildew, club root, dry rot due to *Phoma napobrassicae*, and bacterial rot due to *Bacillus carotovorus*—is mentioned.—M. B. McKay.

712. TURNER, W. F. Spray schedule for Georgia peach season 1922. Georgia State Bd. Entomol. Circ. 36. 4 p. 1922.—Time of application and mixture for both dust and liquid sprays are detailed.—T. H. McHatton.

713. WESTERDIJK, JOHANNA. Passports for plants. Gard. Chron. 71: 224, 246. 1922.—An address at the International Professional Horticultural Conference at the Hague, Apr. 21, 1922, considers present knowledge of fungous and bacterial plant diseases and the danger of their spreading to countries not yet infected. Numerous examples from past experience are given.—*P. L. Ricker.*

PHARMACEUTICAL BOTANY AND PHARMACOGNOSY

H. W. YOUNGKEN, *Editor*

E. N. GATHERCOAL, *Assistant Editor*

(See also in this issue Entries 3, 95, 99, 136, 144, 276, 279, 335, 348, 407, 454, 460, 473, 534, 591, 594, 706, 901, 923)

714. ABE, K., and I. SAITO. Active principle of Korean ginseng. Japan Med. World 2: 166. 1922.—The authors found that the substance in ginseng which has inhibitory action on blood sugar is not extracted by petroleum ether or ether, but by pure alcohol. This active principle of ginseng is said to be a glucosid.—[*Through Jour. Amer. Med. Assoc.*]

715. AMBERGER, KARL. Nachweis fremder Stärke im Getreidemehl. [Identification of foreign starches in cereal flours.] Zeitschr. Untersuch. Nahrungs- u. Genussmittel 42: 181-182. 1922.—Starches are divided into 2 groups according as they are stable to, or dissolved by, diastase at a given temperature (58-59°C., never over 60°C.). Impure preparations of diastase have caused difficulty. Starches of wheat, rye, barley, and oats are destroyed, while those of corn (*Zea mays*), potatoes, beans, and rice are not. The latter may thus be concentrated for microscopic determination when present in small quantities.—*E. E. Stanford.*

716. BAUMANN, K., und J. KUHLMANN. Ermittlung des Zucker- und Fettzusatzes in Hefebackwaren. [Determination of the addition of sugars and fats in bakery products containing yeast.] Zeitschr. Untersuch. Nahrungs- u. Genussmittel 42: 225-232. 1921.

717. BOSMAN, LOUIS PIERRE. Castelin, a new glucoside from *Castela Nicholsoni*. Jour. Chem. Soc. [London] 121: 969-972. 1922.—A glucoside, to which the name castelin was assigned, was prepared from the herb *Castela Nicholsoni*, a member of the *Simarubaceae*. On acid hydrolysis of castelin, crystalline castelagenin was obtained. A bitter principle is also reported to have been found in the bark of *Simaruba amara*.—*F. E. Denny.*

718. BOYER, G. Sur quelques empoisonnements par les champignons. [Mushroom poisoning.] Bull. Trimest. Soc. Mycol. France 37: 134-138. 1921.—Seven cases of mushroom poisoning are reported.—*D. S. Welch.*

719. FEDELI, CARLE. Ricerche sperimentali sull'azione del polline sul cuore degli animali. [Experimental work on the action of pollen on the hearts of animals.] Atti R. Accad. Lincei Roma Rend. Cl. Sci. Fis. Mat. e Nat. 31: 390-391. 1922.

720. GARCIA, F., and R. GUEVARA. Pharmacodynamics of *Datura alba*. Philippine Jour. Sci. 20: 599-609. Pl. 1. 1922.—The alkaloidal content of the seed is 0.5 per cent.—*E. D. Merrill.*

721. GHOSE, MANMATHA N. Further notes on the effect of certain climatic conditions on the cyanogenesis of jowar (*Andropogon sorghum*). Agric. Jour. India 16: 381-387. 1921.—At Sabour, in Bihar and Orissa, temperature and humidity have a great effect on the production and on the rate of disappearance of the cyanogenetic glucoside in this important Indian fodder crop. Even when growth has been retarded by unfavorable climatic conditions, the disappearance of the cyanide has been rapid under high temperatures. Under

low temperatures, the poison persisted for a long time and did not disappear by the addition of excessive moisture to the soil. Appreciable differences in the amount of hydrocyanic acid in plants collected early in the morning and late in the afternoon were also observed.—*A. Howard.*

722. GRIEBEL, C. Die Zellelemente des Maniokmehles. [Cell elements of tapioca flour.] Zeitschr. Untersuch. Nahrungs- u. Genussmittel 43: 169-171. Fig. 1. 1922.—A process is devised for use when the characteristic tapioca (*Manihot utilissima* or *M. palmata*) starch is unrecognizably swollen. Starch is removed by chloral hydrate, weak acid, or alkali. Groups of reticulate tracheids surrounded by porous thin-walled cells, and colorless, dotted stone-cells—usually thick-walled and often accompanied by crystal cells—are described and figured as characteristic. Other cell elements are briefly described and figured, as is also the cross-section of the manioc root.—*E. E. Stanford.*

723. GRIEBEL, C. Krystallinische Kalkabscheidungen in pflanzlichen Objekten durch Einwirkung alkalischer Reagenzien. [Crystalline precipitations of calcium salts in plant tissues by means of alkaline reagents.] Zeitschr. Untersuch. Nahrungs- u. Genussmittel 42: 172-173. Fig. 1-2. 1922.—Sphaero-crystals of calcium carbonate form in cherry (*Cerasus vulgaris*) leaves and some other leaves when these are treated with Javelle's solution. Calcium carbonate also separates in crystalline form from flours when treated with alkali.—*E. E. Stanford.*

724. J[ATUL], P. A. Iš Musū Botanikos Dr. J. B-s. [From our botanist Dr. J. B.] Želmenija 1: 47-48. 1921; 2: 63-64, 79-80. 1922.—Brief notes are given from the Apszvieta by Jonas Basanavičius.—*C. W. Dodge.*

725. PENFOLD, ARTHUR RAMON. A critical examination of the aromatic aldehydes occurring in certain Eucalyptus oils. Jour. Chem. Soc. [London] 121: 266-269. 1922.—Aromatic aldehydes were separated in pure condition from essential oils obtained from the leaves and terminal branchlets of *Eucalyptus hemiphloia* and *E. salubris*.—*F. E. Denny.*

726. SIMONSEN, JOHN LIONEL, and MADYAR GOPAL RAU. The essential oil from *Blumea Malcomii*. Jour. Chem. Soc. [London] 121: 876-883. 1922.—*Blumea Malcomii*, a small woolly-stemmed herb growing in the western part of the Deccan plateau, yielded on distillation an essential oil resembling caraway-seed oil in odor. The young plants gave the highest yield, about 0.25 per cent of the fresh green tissue. The chemical constituents of the oil were isolated and identified.—*F. E. Denny.*

727. SPEGAZZINI, CARLOS. Plantas venenosos para los ganados. [Plants poisonous to stock.] Rev. Soc. Rural Cordoba [Argentina] 21: 5766-5774. 1921.—The author has found that many popular opinions concerning poisonous plants are wrong. He divides Argentine plants into 3 groups with respect to their poisonous properties. The 1st includes those always poisonous, either entirely or in certain organs, including *Nerium* and *Datura* sp.; the 2nd, those that are occasionally poisonous under certain conditions, such as *Sorghum*, *Zea mays*, and *Solanum tuberosum*. The 3rd group includes those found to be always innocuous.—*John A. Stevenson.*

728. VOGT, E. Nachweis und Bestimmung von Streckmitteln in Mehl und Brot. [Demonstration and estimation of adulteration in flour and bread.] Zeitschr. Untersuch. Nahrungs- u. Genussmittel 42: 145-173. 1921.—The author discusses microscopic and chemical studies of the following adulterations: barley-meal, corn-meal, prepared oatmeal, and various potato products. Microscopic work was based on the form and size of starch grains, altered by the baking process, and on the occurrence of natural impurities of the various substances. The diagnosis was aided by differential staining with a weak solution of Congo red in India ink. Diagnosis of potato materials is hindered by extensive alterations of cell-contents. Micro-

scopic quantitative determinations are impracticable. Chemical diagnosis depends upon the "characteristic alkalinity" of the ash. By combined microscopic and chemical means approximately quantitative results may be obtained in some cases.—*E. E. Stanford.*

729. WILCZEK, E. *Note sur les impuretés du cacao.* [Remarks upon the impurities of cacao.] *Schweiz. Apoth. Zeitg.* 59: 120-126. 1921.—This article deals with the impurities (foreign fruits and seed) found in cacao at the time of sorting. Accidental admixture during the drying process and in the great marts of the producing countries is largely blamed. A list is given of the various impurities identified together with the geographical distribution of the mother plant and the source of the cacaos. The impurities are classified by the author as either "caracteristiques," indicating the origin of the cacao, or as "ubiquites," in which it is difficult to form any opinion of origin. Among the former are mentioned *Elaeis guineensis*, *Cocos nucifera*, *Cola vera*, etc., for the Kamerun, and *Cocos* sp., *Euterpe oleracea*, *Phytelphas macrocarpa*, *Bertholletia excelsa*, etc., for tropical America. There is much work to be done on the "ubiquites" group.—*H. W. Youngken.*

730. WOHACK, FRANZ. *Mikroanalytische Verfahren in der Nahrungsmitteluntersuchung.* [Microanalytical methods in food investigations.] *Zeitschr. Untersuch. Nahrungs- u. Genussmittel* 42: 290-299. 1921.—Determinations of vanillin and formic acid are chiefly concerned. Apparatus and methods are described and figured.—*E. E. Stanford.*

PHYSIOLOGY

B. M. DUGGAR, *Editor*

W. J. ROBBINS, *Assistant Editor*

(See also in this issue Entries 32, 33, 91, 94, 95, 119, 188, 191, 193, 195, 203, 208, 210, 215, 220, 226, 228, 285, 405, 410, 440, 443, 452, 460, 533, 537, 540, 673, 687, 691, 692, 698, 717, 721, 725, 726, 848, 849, 851, 852, 853, 856, 857, 863, 868, 873, 879)

GENERAL

731. BANCROFT, WILDER D. *Applied colloid chemistry.* 345 p. McGraw-Hill Book Co.: New York, 1921.—This treatment of the physical chemistry of colloids is intended as an introduction to proposed volumes on the specialized branches of the subject. It is, therefore, very general in its scope. Defining colloids as "any phase which is sufficiently finely divided," it draws material from a wide variety of sources, ranging from war gases and mining processes to eye-color; almost none, however, from biology. This material is treated deductively; a very extensive bibliography is given.—*Mildred L. Johnson.*

732. BERNARD, NOEL. *Principes de biologie végétale.* [Principles of plant biology.] 212 p., 18 fig. Felix Alcon: Paris, 1921.—This forms what is in effect the 2nd volume of a course in botany as presented by the author. The subject matter for the 1st volume of the course appeared in 1918 under the title *L'Evolution des Plantes*. The present volume is divided into 2 parts and is a brief treatise on general plant physiology. In the 1st part there are considered the physiology of the cell, physics of nutrition, metabolism, carbon assimilation, nitrogen nutrition, and external factors. The 2nd part deals with the morphology and physiology of the algae, fungi, and lichens. The concluding chapter is on plant immunity.—*H. C. Young.*

733. MAQUENNE, L. *Précis de physiologie végétale.* [Synopsis of plant physiology.] 172 p. Payot & Co.: Paris, 1922.—This is a brief presentation of physiological principles without illustrations or experiments. In Chapter I are considered such general topics as the composition of the air, the solubility of gases, diffusion, osmosis, colloids, and enzymes. A chapter is devoted to each of the following: germination, growth and carbon

assimilation, nitrogen assimilation, the assimilation of mineral materials, respiration, water movements, migration of foods, and formation of the principal immediate products of nutrition.—*Grace E. Howard.*

734. PETTIBONE, C. J. V. *Physiological chemistry.* 328 p., *Illus.* C. V. Mosby Co.: St. Louis, Missouri. 1922.—This is a general text, including experiments for laboratory work. It is intended primarily for student use, but also for reference by physicians.—*B. M. Duggar.*

PROTOPLASM, MOTILITY

735. BOLTE, ELIZABETH. Über die Wirkung von Licht und Kohlensäure auf die Beweglichkeit grüner und farbloser Schwärmzellen. [On the effect of light and carbon dioxide on the motility of green and colorless swarmspores.] Diss. Leipzig. 37 p. 1920.

736. GRAY, J. The mechanism of ciliary movement. *Proc. Cambridge Phil. Soc.* 20: 352-359. 1921.—This is an experimental study to determine the physiology of the ciliary apparatus—the gills of *Mytilus edulis* (the edible clam) being employed in this instance.—*Michael Levine.*

741. BORESCH, K. Über den Eintritt und die emulgierende Wirkung verschiedener Stoffe in Blattzellen von *Fontinalis antipyretica*. [The penetration and emulsifying action of different compounds in the leaf cells of *Fontinalis antipyretica*.] *Biochem. Zeitschr.* 101: 110-158. 1919.—The author has studied the nature of filiform nodules in the leaf cell of the plant in question and determined their fatty nature by microchemical means. The emulsifying action on these bodies of 4 chemical groups—alcohols, phenols, alkaloids and alkaloidal salts, and ammonia and its derivatives—is considered at length. It was found for alcohols that emulsification was effected by propyl and the higher alcohols but not by those lower in the series. Emulsification is here regarded as related to affinity for the fatty constituents of the nodule rather than to surface tension properties. The phenols were more or less comparable to the alcohols in action, their effectiveness as emulsifiers forming a descending series: thymol, α -naphthol, *o*-cresol, *m*-cresol, phenol, pyrocatechin, resorcin, hydrochinon, pyrogallol, and phloroglucin.—Emulsification by different alkaloids and their salts varied widely, depending in part, apparently, upon permeability. Emulsification was effected in descending order by quinine, cocaine, brucine, strychnine, and codeine. Morphine was entirely ineffective, the cells being practically impermeable thereto. Emulsification by these compounds is attributed to saponification of the fatty substance of the nodule.—In contrast with the results obtained in precipitation of tannin in cell sap by alkaloidal bases and salts, it was found that the threshold concentrations of emulsifying solutions of the free base and salt of an alkaloid were closely approximate. This is accounted for on the ground of permeability of the leaf cell to the alkaloid cation. OH ions intensified emulsification by alkaloids, as did their salts

and free bases, while H ions reduced such action without reducing toxicity, indicated by death of the leaves. The action of ammonia on the nodule is regarded as similar to that of alkaloids. Only those ammonia salts emulsified, the aqueous solutions of which were alkaline. —W. W. Bonns.

742. BRADFORD, S. C. Die reversible Sol-Gel-Transformation. [The reversible sol-gel transformation.] *Kolloid Zeitschr.* 28: 214-217. 1921.

743. FREUNDLICH, H. Ueber den Potentialsprung, der bei der Elektroosmose und verwandten Erscheinungen wirksam ist. [The potential difference, which is effective in electro-osmose and related phenomena.] *Kolloid Zeitschr.* 28: 240-242. 1921.

744. GIRARD, PIERRE, et W. MESTREZAT. Recherches expérimentales sur la perméabilité sélective des cellules vivantes aux ions. Remarque à propos de l'expérience de Donnan sur le rouge Congo. [Researches on the selective permeability of living cells to ions. Comment on Donnan's experiments with Congo red.] *Compt. Rend. Soc. Biol.* 87: 448. 1922.—The authors point out certain differences between their hypothesis of differential permeability and that of Donnan. According to them, whenever there is a preponderance of either H or OH ions in at least 1 of the mediums separated by a permeable membrane, the latter becomes the seat of polarization which is an electrostatic force, and this results in an unequal diffusion of ions which can freely pass through the membrane. In Donnan's experiments with Congo red this is not the case, since the anion of this salt is colloidal and cannot go through the membrane.—S. Morgulis.

745. GIRARD, PIERRE, et W. MESTREZAT. Recherches expérimentales sur la perméabilité des cellules aux ions. Schème physico-chimique de la perméabilité sélective. [Experimental researches on the permeability of cells to ions. A physico-chemical scheme of selective permeability.] *Compt. Rend. Soc. Biol.* 87: 356-357. 1921.—The authors studied the passage through animal membranes of the ions of a neutral salt in the presence of an acid with a different anion. From these experiments they suggest an hypothesis to account for the fact that the ions of the salt do not pass in chemically equivalent amounts. This they ascribe to a polarization of the membrane as a result of which an electrical equilibrium is established on both sides of the membrane with the anions and cations of the salt unevenly distributed. [See also following entry.]—S. Morgulis.

746. GIRARD, PIERRE, W. MESTREZAT, et LI-SHOU-HOUA. Recherches expérimentales sur la perméabilité des cellules aux ions. Schème physico-chimique de la perméabilité sélective. [Experimental researches on the permeability of cells to ions. A physico-chemical scheme of selective permeability.] *Compt. Rend. Soc. Biol.* 87: 358-360. 1922.—[See also preceding entry.]

747. HANDOVSKY, H., und A. WEIL. Die Quellung von Kolloid-Gemischen. I. [The swelling of colloid mixtures. I.] *Kolloid Zeitschr.* 27: 306-311. 1920.—Preliminary to the study of the water-holding power of the components of protoplasm the authors have begun the investigation of other colloid mixtures. The addition of charcoal in amounts up to 0.3 gm. per gm. dry gelatin made as a 20 per cent gel exerts no observable effect upon the swelling of the mixture, but more than this amount of carbon diminishes the swelling. Mixtures of gelatin and lipid behaved similarly. The authors consider that there is an adsorption compound formed that varies with each change in the amounts of the components to form a substance often very different in its properties with but a small change in its composition, water being shared by the components of the complex.—H. E. Pulling.

748. HATSCHKE, E. Die Eigenschaften von elastischen Gelen. [The properties of elastic gels.] *Kolloid Zeitschr.* 28: 210-213. 1921.

749. HATSCHKE, EMIL. Diffusion in deformed gels. Sci. Prog. [London] 17: 86-94. 3 fig. 1922.—A study of elastic gels showed that they remain isotropic for diffusion under stress, and the diffusion velocity is the same in the deformed and in the unstressed gel.—J. L. Weimer.

750. KOPACZEWSKI, W. Les colloïdes et la vie. Rev. Sci. Pures et Appl. 33: 358-364. 1922.—This is a general statement of the importance of colloids in every day life, and treats first of their importance in biology. Osmotic pressure is explained as due to the inflation and deflation of the colloids comprising the cell membrane. Form, growth, and movement are regarded as colloidal phenomena. Fecundation of the egg has been proved to be due to the formation of asters and the asters are the result of the coagulation of the colloids of the plasma—the passage of a sol to a gel. The importance of colloids in physiological functions such as nutrition, nerve functioning, and secretion is stressed.—H. W. Anderson.

751. LUERS, H., und M. SCHNEIDER. Zur Messung der Solvation (Quellung) in Kolloïden. [Measurement of the solvation (swelling) of colloids.] Kolloid Zeitschr. 28: 1-4. 1921.—A method is described by which the viscosity of the colloid in powder form in water is determined and this is shown to change parallel to the change in volume of the colloid.—H. E. Pulling.

752. LYON, T. L., and J. K. WILSON. Liberation of organic matter by roots of growing plants. Cornell Univ. Agric. Exp. Sta. Mem. 40. 7-43. 1921.—The plants were grown under sterile conditions in full nutrient solutions. The containers were flasks of 8 or 12 l. capacity. In experiments with maize, oats, pea, and vetch it was found that the nutrient solution used for each of these plants contained at the conclusion of the experiment an appreciable amount of organic nitrogen, exclusive of the amount present in the residual plant cells found in the precipitate of the solution. Maize was grown for a period of 53 days. In 4 cultures the dry weights of the individual plants varied from approximately 17 to 24 gm. The amounts of organic matter excreted from the roots varied from 353 to 466 mgm. The maximum ratio of organic matter excreted to the dry weight of the plant was 1:37. Some evidence is presented to show that peroxidase is liberated into the nutrient solution.—L. Knudson.

753. MESTREZAT, W., PIERRE GIRARD, et V. MORAX. Recherches expérimentales sur la perméabilité cellulaire. Perméabilité de la cornée de l'oeil vivant. [Experimental researches on cellular permeability. Permeability of the cornea of the living eye.] Compt. Rend. Soc. Biol. 87: 144-147. 1922.—The cornea is a double cellular membrane and lends itself for the experimental study of permeability *in vivo*. This was done by enclosing the eye of a rabbit (previously treated with novocaine) in a special glass bulb well fitted into the orbit and filling the bulb with the test solutions. After exposure for 30 minutes, the eye was carefully washed and the contents of the anterior chamber removed with a fine needle for analysis. The other eye served as the control. $\text{Ca}(\text{NO}_3)_2$ and MgSO_4 were used. The anions and cations of these salts do not penetrate through the cornea in equivalent amounts. Thus, 2 ions of (NO_3) go with 0.03-0.54 ions of (Ca) ; 1 ion of (SO_4) for every 0.38-0.65 ions of (Mg) . The acidity of the medium may increase the permeability, but it does not change the proportion of the ions.—S. Morgulis.

754. MÖLLER, H. P. Rhythmische Fällungserscheinungen in pflanzlichen Zellmembranen. [Rhythmical precipitation in plant cell walls.] Kolloidchem. Beih. 14: 97-146. 1921.—This is an experimental and theoretical study of zone formation with silver nitrate in the walls of cells from seed of wheat (several unnamed varieties), barley, oats, rye, *Brachypodium pinnatum*, from leaves of *Sedum maximum*, *Griselinia macrophylla*, and several unnamed plants. The bands in different tissues were of different degrees of distinctness and of different widths. The mechanism of formation of these bands is believed to be identical with that forming Liesegang's rings in gelatin and this conclusion is supported by: the form and structure of the bands, and the influence of outer conditions (validity of Fick's diffusion

law, influence of water content of the walls, concentration of silver nitrate employed, influence of precipitating salts in the wall, and the diffusion rate of silver nitrate). The results give further evidence of the colloidal nature of cell walls in plants. The corky integument and not the cellulose membrane is selectively permeable in the cereal grains. Photomicrographs illustrate the paper.—*H. E. Pulling.*

755. PIETRKOWSKI, G. Die Wirkung des Strophanthins auf Kolloide. [The effect of strophanthin on colloids.] *Biochem. Zeitschr.* 98: 92-104. *Fig. 1-6.* 1919.—By virtue of its high surface tension, strophanthin effects a precipitation of colloidal solutions. In the presence of hydrophilous colloids, such as gelatin, it reduced the swelling capacity of the latter.—*W. W. Bonns.*

WATER RELATIONS

758. MASON, F. A. Revival of sporophores of *Schizophyllum commune*. *Nature* 109: 272-273. 2 *fig.* 1922.—Hairs forming the covering of the pileus show remarkable avidity for water. The rate of absorption is much greater than that of ink by blotting paper. This property probably enables the fungus in xerophytic exposures to take full advantage of small amounts of water.—*O. A. Stevens.*

759. MONTFORT, C. Tatsachen und Probleme der Moorökologie. [Facts and problems relating to the ecology of bogs.] *Sitzungsber. Naturhist. Ver. Preussisch. Rheinlande u. Westfalens* 1919: A14-A20. 1920.—The paper here reported was read at a meeting of the Natural History Society of Westphalia and the Prussian Rhine in June, 1919, and is largely devoted to a consideration of Schimper's theory of physiological dryness in bogs. The author first describes a series of guttation experiments, carried on with seedlings of Indian corn placed in solutions of various kinds. Poisonous and strongly osmotic solutions stopped the guttation completely, and reasons are given to show that this means an inhibition of water-absorption as well. Bog water, however, had little or no effect on the guttation, and the conclusion is therefore reached that physiological dryness of the environment is not the cause of the xerophytic features of bog plants.—*A. W. Evans*

760. PERALTA, FERNANDO DE. The control of soil moisture by means of auto-irrigators. *Philippine Agric.* 10: 467-477. 3 *fig.* 1922.—Lettuce (*Lactuca sativa*) was grown in pots watered by means of Livingston porous-cup auto-irrigators. The soil moisture content was kept nearly constant. A noteworthy gain in leaf area and dry weight was secured by using auto-irrigation, as compared with periodic watering.—*Sam F. Trelease.*

761. TRELEASE, SAM F. Incipient drying and wilting as indicated by movements of coconut pinnae. *Amer. Jour. Bot.* 9: 253-265. 1 *fig.* 1922.—Running ventrally along each side of the midrib of the pinna of the coconut leaf is a narrow strip of tissue, the "hinge," through the action of which the 2 wings of the pinna may take various positions. When the leaf is well supplied with water they are in approximately the same plane, but when there is a deficiency of water the 2 wings revolve downward, their lower faces approaching each other. In excised samples the angular divergence of the wings was measured and was found to be closely correlated with the water content of the leaf. In leaves attached to the plant the size of this angle may therefore be used as a measure of the water content of the leaf. Using this method, the greatest incipient drying was found to occur in the coconut between 1 and 3 p.m. Individual differences were observed between different plants as to the period of greatest drooping of the wings. The importance of such methods in providing a basis for proper cultivation is emphasized.—*E. W. Sinnott.*

MINERAL NUTRIENTS

762. EHRENBERG, PAUL. *Das Kalk-Kali-Gesetz.* [The calcium-potassium law.] *Landw. Jahrb.* 54: 1-159. 1919.—If a plant poorly supplied with potassium is supplied liberally with calcium, there results a decreased absorption of potassium which may have detrimental effects upon the plant. These effects may be overcome by increasing the potassium content of the fertilizer. Results of numerous experiments are reported in support of this law. Buckwheat and summer wheat were used and the dry weight, potassium, nitrogen, and phosphoric acid content of the plants were determined. A large supply of calcium was found to be responsible for a reduction in the absorption of potassium and also for the reduction in dry weight of the plants. If, however, sufficient potassium was added in time, the injury was wholly averted and the yield somewhat increased. A rather complete digest of the literature bearing on the calcium-potassium law is given.—A. R. C. Haas.

763. ESPINO, RAFAEL B. *Mineral requirement of rice.* *Philippine Agric.* 10: 313-319. 1922.—A review is presented of the literature on the mineral nutrient requirements of rice.—Sam F. Trelease.

764. GERICKE, W. F. *On the physiological balance in nutrient solutions for plant cultures.* *Amer. Jour. Bot.* 9: 180-182. 1922.—Instead of using a single complete nutrient solution for growing wheat seedlings, the author used 3, each one containing (in addition to iron) 2 of the essential elements. The plants were placed in each of these in succession for a day, and this rotation continued for 4 weeks. Six different combinations of these single-salt solutions were used in which the various elements were paired in different ways, and marked differences in the growth of the seedlings were noted between these combinations. Where KNO_3 , MgHPO_4 , and CaSO_4 were the 3 salts used, growth was almost as great as in a complete nutrient solution. Where KH_2PO_4 , CaSO_4 , and $\text{Mg}(\text{NO}_3)_2$ were used, growth was less than half as great. The author believes that the availability and utilization of essential elements by wheat seedlings are affected by the way in which these elements, presumably as ions, are paired. The utilization of nitrates, for example, seems to depend upon the supply of available potassium. Other cation-anion relations are also evident.—E. W. Sinnott.

765. JUNG, JOSEF. *Über den Nachweis und die Verbreitung des Chlors im Pflanzenreiche.* [The detection and the distribution of chlorine in plants.] *Sitzungsber. K. Akad. Wiss. Wien (Math.-Nat. Kl.) Abt. I.* 129: 297-340. 1 pl. 1920 [1922].—The most successful reagents for the detection of chlorine are: (a) thallium acetate 0.5 gm., glycerine 2 gm., distilled water 7.5 gm.; (b) silver nitrate 0.05 gm., 10 per cent ammonia 9.95 gm. The former gives very characteristic crystals but is not delicate enough for small traces of chlorides; silver nitrate is extraordinarily sensitive, and the crystals formed show a delicate and characteristic response to light.—A series of plants from bacteria and myxomycetes to spermatophytes, embracing 137 families and 604 species, were examined for chlorine content. Various ecological groups of seed plants were similarly tested. Such subdivisions as Equisetaceae, Cannabaceae, Amentiferae, Cruciferae, Euphorbiaceae, Umbelliferae, Compositae, Liliaceae, and Iridaceae are particularly rich in chlorine content, while other groups, such as the fresh water Cyanophyceae and Chlorophyceae, lichens, bryophytes, ferns, club mosses, conifers, Betulaceae, Salicaceae, Rosaceae, Ericaceae, and Orchidaceae contain very small quantities,—in fact, few plants were found which contained no demonstrable amounts.—Chlorine occurs as chlorides dissolved in the cell sap. There is a progressive increase in chloride content from the root upward; the largest quantities are found in the apical portion of the stem, the bast parenchyma, and the petiole and veins of the leaf; the leaf mesophyll, the epidermis, the flower parts, guard cells, and woody tissues contain mere traces of, or are free from, chlorides.—Plants characteristic of moist soils, rich in minerals, have the highest chloride content, those of moorlands and sandy soils generally lack it. The absence of chlorides among mosses, ferns, woody plants, epiphytes, and saprophytes is noteworthy.—F. Weiss.

766. MERKENSCHLAGER, FRITZ. *Die Chlorose der Lupine auf Kalkböden.* [The chlorosis of lupine on soils rich in lime.] *Fühling's Landw. Zeitg.* 70: 19-24. 1921.

767. MITSCHERLICH, A. *Vegetationsversuche mit physiologischen Reaktionen.* [Experiments with the physiological reactions of plants.] *Landw. Jahrb.* 54: 477-492. *Pl.* 5-6. 1919. —The author discusses the results of applying various amounts of fertilizer salts to sand cultures in which annual plants were grown. The increase in yield accompanying an increase in fertilizer salts follows, to a certain point, a logarithmic curve. Comparisons are given showing the effect of acid or of alkaline conditions on the yields produced by sodium nitrate, ammonium sulphate, urea, and urea nitrate.—*H. S. Reed.*

768. SKINNER, J. J., and F. R. REID. *Nutrient requirements of clover and wheat in solution cultures.* *Soil Sci.* 12: 287-300. *Pl.* 1, 3 fig. 1921.—Culture solutions with a concentration of 80 parts per million of P_2O_5 , NH_3 , and K_2O were used. Sixty-six solutions in all were employed, some containing each of the salts singly, combinations of 2, and combinations of 3, the ratio of the constituents varying in 10 per cent differences using the familiar triangular plan. Their results seem to verify the common belief that clover is a heavy potash-feeding plant and in general indicate that clover requires a higher proportion of K than of N or P, inasmuch as K was shown to be absorbed in larger proportion than P or N. In the case of wheat, better growth occurred with all 3 of the nutrient elements present, the best growth being in mixtures containing between 10 and 30 per cent PO_4 , 30 and 60 per cent NO_3 , and 30 and 60 per cent K. Greatest absorption occurred in the cultures with greatest growth.—*I. T. Scott.*

769. STUTZER, A. *Düngung mit Kohlensäure.* [Fertilizing with carbon dioxide.] *Illustr.* *Landw. Zeitg.* 42: 107-108. 1922.—Experiments are cited to show the greatly increased yield of tomatoes due to increased supply of carbon dioxide. The author advocates the handling of manure so as to favor optimum aerobic conditions for the bacteria and thus secure maximum supply of carbon dioxide.—*John W. Roberts.*

770. TOTTINGHAM, W. E., and E. J. RANKIN. *Nutrient solutions for wheat.* *Amer. Jour. Bot.* 9: 270-276. 1922.—The optimal nutrient conditions for wheat, as regards reaction, appear to differ as between the germination phase and the later growth of the plant. Hydrogen-ion concentrations which are endured by the plant in intermittently renewed solutions become unendurable when the solution is continuously renewed. Certain pH values which restrict the elongation of stem and root appear to favor the production of dry matter in these organs.—*E. W. Sinnott.*

771. ZIEGENSPECK, H. *Lassen sich Beziehungen zwischen dem Gehalte an Basen in der Asche und dem Stickstoffgehalte der Pflanzen aufstellen, die einen Rückschluss auf die Ernährungsart und die Excretion gestatten?* [Is it possible to establish relationships between the content of bases in the ash and the nitrogen content of the plant which permit a conclusion as to the plant's mode of nutrition and excretion?] *Ber. Deutsch. Bot. Ges.* 40: 78-85. 1922.—The author was prompted to this investigation by Stahl's observation that mycotrophic plants are characterized by a very small ash content. The starting point was the consideration that independent plants secure almost all their nitrogen in the form of salts of nitric acid. Therefore, if the nitrogen content of the plant were reduced to the base equivalent, an indicator would be secured of the manner in which nitrogen is absorbed or of the degree of salt excretion. The base equivalent was calculated as potassium, the ash being evaporated with hydrofluoric and sulphuric acids, and its weight multiplied by K_2/K_2SO_4 . This was then compared with the nitrogen equivalent for nitrates. In the case of mycotrophic plants (except where the presence of considerable iron interfered with the calculations) the nitrogen equivalent overbalanced the base equivalent. In the case of some only slightly mycotrophic plants the base equivalent was slightly in excess of the nitrogen equivalent. In many autotrophic plants a large base excess was found. In most of these cases there was no guttation. Where the nitrogen equivalent in autotrophic plants exceeded the base equivalent the author attributes this to the effect of guttation. In the case of mycotrophic, parasitic, and ammonia plants he attributes it to nitrogen taken in as nitrate. In the case of

autotrophic plants, especially orchids with which the author especially concerned himself, there was an increasing nitrogen equivalent excess with increase in mycotrophy. Analyses of acid soils upon which mycotrophic plants were growing showed practically no nitrogen as nitrate, but considerable as ammonia, or in other forms.—*Anna Sommer.*

PHOTOSYNTHESIS

772. BÜRGI, E., und C. F. VON TRACZEWSKI. Ueber die biologischen und pharmakologischen Eigenschaften des Chlorophylls. [The biological and pharmacological properties of chlorophyll.] *Biochem. Zeitschr.* 98: 256-283. 1919.—Experiments are reported with chlorophyll and with phaeophytin preparations on canaries previously rendered anaemic, to determine the effect of these substances on blood formation. The results indicate that both are effective in rebuilding blood corpuscles under the conditions noted.—*W. W. Bonns.*

773. GRIGORIEW, R. Ueber die blutbildenden Eigenschaften des Chlorophylls. [The blood building properties of chlorophyll.] *Biochem. Zeitschr.* 98: 284-293. 1919.—A confirmation and extension of the work of Bürgi and von Traczewski [see preceding entry] is afforded.—*W. W. Bonns.*

774. JACOBY, M. Über den Formaldehyd als Übergangsstufe zwischen der eigentlichen Assimilation und der Kohlenhydratbildung in der Pflanze. [Formaldehyde as the intermediate between true assimilation and carbohydrate formation in the plant.] *Biochem. Zeitschr.* 101: 1-6. 1919.—Starting with Willstätter's hypothesis of formaldehyde as the end product of the specific assimilation process preceding carbohydrate formation, the author attempts to demonstrate the direct utilization of the aldehyde by green leaves in darkness. Material studied was the abscised leaf of *Tropaeolum majus*, the petioles being immersed in water through cork stoppers which were rendered water tight with paraffin. Before being used in the experiment the leaves were kept in darkness for 48 hours. Apparatus is described by means of which the leaves were surrounded by an atmosphere of CO₂-free air and formaldehyde vapor, provision also being made for a sufficient degree of humidity in the experimental chamber.—One brief table is presented as representative of the kind of data secured. This shows that leaves subjected to formaldehyde from 24½ to 32 hours increased in dry weight from 12 to 15 per cent, as compared with an increase of 1.7 to 5.4 per cent in the controls. The author concludes that the aldehyde is "fixed" by the plant, but ventures no further opinion as to its subsequent conversion.—*W. W. Bonns.*

775. SIEBERT, ALFRED. Ergrünungsfähigkeit von Wurzeln. [Greening capacity of roots.] Dissertation. 37 p. Kiel, 1920.

776. WARBURG, O. Ueber die Geschwindigkeit der photochemischen Kohlensäure-zersetzung in lebenden Zellen. [The rate of CO₂ decomposition in living cells.] *Biochem. Zeitschr.* 100: 231-270. Fig. 1-11. 1919.—An extended study is made of factors affecting the rate of CO₂ decomposition, using the green alga, *Chlorella*. Cultural methods (nutrient solutions) and algal characteristics are described. Experimental methods, apparatus, and principles and formulae involved in the calculation of the data are given in detail. The factors affecting CO₂ decomposition and the results obtained may be summarized as follows: (1) CO₂ concentration. Using amounts of gas varying from $\frac{1}{20}$ to 10 times that of the mean atmospheric concentration, the assimilation rate in constant light intensity was proportional to the CO₂ concentration for the lower values; for the higher values (2×10^{-6} mols. per l. and upwards) assimilation still increased, but at a lower ratio. (2) Light intensity. At low intensities the assimilation rate was approximately proportional to illumination intensity. This fact together with that enunciated in (1) establish the inference that assimilation is proportional to the concentration of a "photo-chemical primary product" and the concentration of a secondary product with which the former reacts. (3) Temperature. Making corrections for concentration changes due to temperature differences, the temperature coefficient varied markedly with temperature and light intensity—at low intensity and moderate

temperatures (15–32°C.) the coefficient was unity. (4) Intermittent illumination. CO_2 decomposition was greater with intermittent light of high intensity than with continuous exposure of the same. With low intensity, no difference between continuous and intermittent exposure was observable. These results are discussed in relation to the work of Brown and Escombe. (5) Substances affecting permeability. Phenylurethan and cyanic acid showed in general similar results, dilute solutions effecting marked assimilatory inhibition, while respiration, in the case of the lower of such concentrations, was stimulated.—*W. W. Bonns.*

METABOLISM (GENERAL)

777. BIEDERMANN, W. *Der Lipidgehalt des Plasmas bei Monotropa hypopitys und Orobanche (speciosa).* [The lipid content of the protoplasm of *Monotropa hypopitys* and *Orobanche (speciosa).*] *Flora* 113: 133–154. *Pl.* 4–5. 1919.—Because of the close association between chlorophyll and lipid substances in the chloroplasts of living leaves and because some experiments seemed to indicate that chloroplasts contain a greater proportion of lipid than the surrounding protoplasm, the author investigated the lipid content of the plants named in the title. These are parasitic, chlorophyll-free plants. Previous work on seed did not permit him to conclude that lipids were contained in the protoplasm. The protoplasm is rich in lipids, however, (about 5 per cent of the dry weight of *Monotropa* was a lecithin-like substance) and this appears to be distributed in 2 distinctly different ways: as crumbly masses evenly throughout the cell and as small drops or compact bodies that have a definite place in the cell, which leads the author to believe that “a lipid must be pre-existent, at least as an ‘Anlage.’” Drawings of the lipid bodies and detailed descriptions of the tissues and chemical methods are given.—*H. E. Pulling.*

778. CURREY, GEOFFREY SAUNDERS. *The colouring matter of the scarlet Pelargonium.* *Jour. Chem. Soc. [London]* 121: 319–323. 1922.—“The anthocyan pigment contained in the petals of the scarlet pelargonium, James Kelway, is, therefore, the diglucoside pelargonin (pelargonidin [1 mol.] + dextrose [2 mol.]).” It was found to occur as an oxonium salt to the extent of about 6 per cent of the dry weight of the petals. Pure crystals of the anthocyanin chloride and anthocyanidin chloride were prepared by methods described in detail.—*F. E. Denny.*

779. EICHELBERGER, MARIETTA. *The carbohydrate content of navy beans.* *Jour. Amer. Chem. Soc.* 44: 1407–1408. 1922.

780. FORSTER, MARTIN ONSLOW, and WILLIAM BRISTOW SAVILLE. *Constitution of picro-rocellin, a diketopiperazine derivative from Roccella fuciformis.* *Jour. Chem. Soc. [London]* 121: 816–827. 1922.—Evidence regarding the constitution of picrorocellin, a colorless, crystalline, bitter substance, was obtained from *Roccella fuciformis*, a lichen, “probably coming from the west coast of Africa.” It was found to be a nitrogenous compound $\text{C}_{26}\text{H}_{22}\text{O}_4\text{N}_2$, and on this account was regarded as of especial interest because of the lack of reports, heretofore, describing nitrogenous substances isolated from lichens.—*F. E. Denny.*

781. KLEIN, GUSTAV. *Studien über das Anthochlor.* [Studies of anthochlor (anthoxanthin).] *Sitzungsber. K. Akad. Wiss. Wien [Math.-Nat. Kl.] Abt. I.* 129: 341–395. 1 *pl.* 1920 [1922].—Anthochlor is the name given by Prantl to a yellow color substance dissolved in the cell sap of yellow flowers and fruits. It is to be distinguished from anthocyanin by its color, from carotin and xanthophyll which are contained in plastids, and from flavones and xanthenes which occur as crystals. A survey of plants with yellow flowers was made to determine the occurrence and distribution within the plant of anthochlor. The presence of anthochlor was determined by microscopic examination and by water extraction. A chemical study was made of its properties, which showed anthochlor to be related to anthocyanin in constitution, properties, and distribution. In some respects, such as resistance to concentrated alkalies and the formation of crystalline acid-addition products with sulphuric acid, anthochlor resembles flavones. The existence of 3 types of anthochlor differing in their

reactions with acids and alkalies, and characteristic of different plants is indicated.—The shade or intensity of the yellow color of flowers bears no relation to the presence of anthochlor or colored plastids; sometimes the color may be due exclusively to one or the other in very closely related species, or plastids and dissolved coloring matter may occur together, the colored cell sap then occupying the outer border of the cell, or the tips of papilliform cells, while the plastids or crystals lie near the inner border.—*F. Weiss.*

782. MAIGE, A. *Influence de la concentration des solutions organiques sur la formation de l'amidon dans les cellules végétales.* [Influence of the concentration of organic solutions on the formation of starch in plant cells.] *Compt. Rend. Soc. Biol.* 86: 856-857. 1922.—Experimenting with beans, the author found that starch begins to appear in plants grown in a 0.2 per cent solution of sucrose (the cotyledons were cut away) and increases in amount with the increasing concentration of the sugar up to 10-15 per cent. With solutions of still greater concentration of the sucrose the starch content of the plant cells rapidly diminishes.—*S. Morgulis.*

783. MÜLLER, FRITZ. *Ueber eine Verbesserung der biologischen Bewertung pflanzlicher Gerbstoffe.* [An improvement of the biological determination of plant tannin.] Dissertation. 37 p. Carl Henstorffs: Rostock, 1919.—The author reviews the various quantitative methods for the determination of tannin and especially the red corpuscle method of Kobert. On the basis of a large number of experiments he suggests the addition of acid to the corpuscle solution as an improvement over the old procedure.—*A. F. Camp.*

784. NIERENSTEIN, MAXIMILIAN. *Catechutannins. Part I. Paullinia tannin.* *Jour. Chem. Soc. [London]* 121: 23-28. 1922.—Paullinia tannin was prepared in crystalline condition from the seed of *Paullinia cupana*. "It is soluble in alcohol, ethyl acetate, or acetic acid, but not in any other organic solvent." It gave color tests of the catechutannins and was precipitated by gelatin and alkaloids. The sodium and potassium salts, and the methylo-derivative of the tannin were formed. When a solution of the tannin was treated with emulsin from bitter almonds, dextrose and optically inactive β -gambier-catechin carboxylic acid were obtained.—*F. E. Denny.*

785. NIERENSTEIN, MAXIMILIAN. *The constitution of catechin. Part IV.* *Jour. Chem. Soc. [London]* 121: 604-613. 1922.—Two different specimens of *Acacia catechu* extract were used for the preparation of a catechin in crystalline condition. Details of methods used in preparing derivatives are given, and proofs offered regarding their molecular arrangement.—*F. E. Denny.*

786. NOACK, KURT. *Der Betriebstoffwechsel der thermophilen Pilze.* [Basal metabolism of the thermophilic fungi.] *Jahrb. Wiss. Bot.* 59: 413-466. 1920.—A study of growth and respiration in a synthetic medium and in hay decoction was made on *Thermoascus aurantius*, *Anixia spadicea*, and *Mucor pusillus*. The data are presented under 5 divisions: basal metabolism at the optimum temperature, the influence of temperature on respiratory activity, the effect of the media on respiration, the influence of zinc sulphate on the respiratory activity at different temperatures, and respiration at reduced oxygen pressures. The respiratory quotient, $\frac{\text{CO}_2}{\text{O}_2}$ for the thermophilic fungi was normal for glucose, 1-1.09. The temperature quotient was low, i.e., the respiratory activity at the higher temperatures did not increase with the increase in temperature according to Van't Hoff's law. The economy coefficient was of the same order as that of the non-thermophilic fungi. The respiratory quotient was unchanged by reduction of temperature. *Thermoascus* reacted very quickly to changes in the composition of the media. Reduction in the O_2 pressure caused no change in the respiratory quotient but there was a marked increase during anaerobiosis.—*W. H. Chambers.*

787. PERKIN, ARTHUR GEORGE, and YOSHISUKE UYEDA. *Occurrence of a crystalline tannin in the leaves of Acer ginnala.* *Jour. Chem. Soc. [London]* 121: 66-76. 1922.—From

the leaves for *Acer ginnala* (Korean maple tree) an extract containing about 30 per cent tannin is used in Japan and China for cotton and silk black-dyeing. The chemical nature of the yellow coloring and tannin matters in the leaves was investigated. A crystalline tannin (termed acertannin), an amorphous tannin, ellagic acid, quercitin, and a "small amount of a phlobo-(catechol) tannin" were found. Acertannin gave deep blue and black colors on cotton, and was regarded favorably as a black dye for silk. The yellow coloring matter was crystallized out and found to be quercitin. The khaki color produced on wool by the leaf extract was attributed to the ellagic acid and quercitin rather than to the tannin itself.—*F. E. Denny.*

793. HONCAMP, F. Wie Können billigst eiweissreiche Futtermittel angebaut und hergestellt werden? [How can cheap protein-rich feeds be prepared?] Landw. Jahrb. 57: 107-137. 1922.—This is a general account of principles of variety selection, fertilization, conservation, and improved methods of utilization.—*Selman A. Waksman.*

794. LOEB, JACQUES. Proteins and the theory of colloidal behavior. 292 p., 80 fig. McGraw-Hill Book Co.: New York, 1922.—This book is concerned with the demonstration of the correctness of 2 important laws for proteins and with the explanation of the chemical and physical properties of proteins by the use of the 2 laws. It is first demonstrated that a protein is amphoteric, and when it exists on the acid side of the isoelectric point it reacts with anions according to ordinary stoichiometric laws, and on the alkaline side of the isoelectric point it reacts with cations. Thus in solutions of sodium chloride or hydrochloric acid of a pH of 4.7 or less gelatin exists as gelatin chloride. In solutions of sodium chloride or sodium hydroxide of pH greater than 4.7 it exists as sodium gelatinate. At the isoelectric point, pH 4.7, it can combine with neither cation nor anion. The second fact made use of to explain the action of proteins is Donnan's theory of membrane equilibria, which states that when a membrane separates 2 solutions of electrolytes one of which contains 1 ion which cannot diffuse through the membrane, the result will be an unequal distribution of the diffusible ions on opposite sides of the membrane. If gelatin chloride is placed in a solution of HCl

the relative concentration of free hydrochloric acid inside and outside the gelatin at the time of equilibrium is determined by the equation $x^2 = y(y + z)$, where x is the concentration of the hydrogen and chlorine ions outside, y is the concentration of the hydrogen and chlorine ions of the free HCl inside, and z is the concentration of the chlorine ions in combination with the gelatin. The 2 laws given above are used to replace hypotheses such as those of adsorption, the Hofmeister ion series, and hydration and dispersion hypotheses used to explain the combination of proteins with salts, their viscosity, swelling, osmotic pressure, etc.—*W. J. Robbins.*

METABOLISM (ENZYMES, FERMENTATION)

795. BACHRACH, E., et H. CARDOT. Influence de l'acidité initiale et de la concentration du milieu sur la marche de la fermentation lactique. [Influence of the initial acidity and of the concentration of the medium on lactic acid fermentation.] *Compt. Rend. Soc. Biol.* 86: 1127-1129. 1922.—With $\frac{1}{2}$ -2 per cent lactose the optimum initial acidity of the medium does not vary and seems to be proportional to the peptone concentration. Thus, with bouillons containing 10 gm. lactose per l. and 0.62, 0.31, and 0.155 per cent peptone, the optimum initial acidity was found to be 0.084, 0.042, and 0.021 N. Under conditions of optimum acidity, the concentration of lactose being constant, the rate of fermentation increases with the peptone concentration. In media containing 11.5, 6.4, 4.5, 3.1, and 1.4 gm. nitrogen per l. respectively, the lactic acid developed in 24 hours was 1.26, 1.02, 0.92, 0.68, and 0.50 N.—*S. Morgulis.*

796. BOKORNY, T. Beitrag zur Kenntnis der chemischen Natur der Enzyme. [The chemical nature of enzymes.] *Biochem. Zeitschr.* 100: 100-113. Fig. 1. 1919.—The author calls attention to the general similarity in proportions of the constituents of enzymes as shown by previous analyses, and determines the amino nitrogen of 11 enzyme preparations. The method is based on the reaction of alkyl-amino substances with nitrous acid: $RNH_2 + HNO_2 = ROH + H_2O + N_2$. The nitrogen is determined by gas displacement rather than by absorption. The data appear to add little to the generally accepted view of the protein nature of enzymes, under present standards of purity.—*W. W. Bonns.*

797. EULER, H., und O. SVANBERG. Zur Kenntnis der Pektase-Wirkung. [The action of pectase.] *Biochem. Zeitschr.* 100: 271-278. 1919.—The authors review briefly the comparatively scant literature on pectase and give results of studies with expressed juice of *Ribes nigrum*, *R. rubrum*, and *R. grossularia*. Acidity was determined in terms of pH. The results show that these species have a closely related natural acidity, the pH ranging from 2.8 to 2.96. The optimum for enzyme action, determined by addition of acid and alkali, appeared to be pH 4.3. No pectase specificity was evident, the enzyme of one species coagulating about equally effectively the juice of another.—*W. W. Bonns.*

798. FAWCETT, GEO. L. Estudio sobre levaduras productoras de alcohol. [Studies on alcohol-producing yeasts.] *Rev. Indust. Agric. Tucuman* 11: 100-103. 1921.—Experiments were carried out with a number of strains of yeasts obtained from distilleries engaged in making industrial alcohol from waste molasses. Certain of these gave a higher per cent of alcohol, indicating possibilities of selecting improved strains for commercial use.—*John A. Stevenson.*

799. HAEHN, H. Die Melaninbildung im autolysierenden Kartoffelpresssaft. [Melanin formation in the autolysis of potato juice.] *Biochem. Zeitschr.* 100: 114-129. 1919.—The author has studied the formation of melanin formed by tyrosinase action in the expressed juice of a number of potato varieties. The melanin standard is expressed in terms of cc. of 0.002 normal potassium permanganate solution necessary to decolorize 1 cc. of the boiled and filtered juice. Amino nitrogen content was also determined.—Melanin content varied considerably in the varieties tested. The autolytic values of the various extracts were obtained from the differences in melanin content before and after autolysis at a definite temperature. Storage of tubers for 6 months increased amino acid content and decreased tyrosinase action. Juice rendered slightly alkaline gave increased melanin formation.—*W. W. Bonns.*

800. MORDHORST, G. Über die Verbreitung eines Tannin und verwandte Stoffe spaltenden Enzyms im Organismus des Menschen und einiger Tiere. [The distribution of enzymes attacking tannins and related compounds in the body of man and some other animals.] Dissertation. 40 p. Carl Hinstorffs: Rostock, 1919.—The author discusses the chemistry of tannins, methods for detection of tannic and gallic acid, and the location of tannin-splitting enzymes in the animal body. He found tannin-splitting enzymes in the intestinal juices and liver, but not in saliva, gastric juice, blood serum, kidney, or spleen. A similar study was made of etelen, or trigallacetol; a triacetylethyl ester of gallic acid; tannigen, an ester formed from acetic acid and tannin; and tannoform, a condensation product of tannin and formaldehyde.—*H. C. Young.*

801. NEUBERG, C. Die physikalisch-chemische Betrachtung der Gärungsvorgänge. [The physico-chemical view of fermentation processes.] *Biochem. Zeitschr.* 100: 289-303. 1919.—This is a reply to Ostwald's criticisms [see *Bot. Absts.* 12, Entry 804].—*W. W. Bonns.*

802. NEUBERG, C., und J. HIRSCH. Die dritte Vergärungsform des Zuckers. [The third fermentation form of sugar.] *Biochem. Zeitschr.* 100: 304-322. 1919.—As a continuation of sugar fermentation studies in presence of alkaline salts, the authors studied the effect of potassium carbonate, dipotassium phosphate, magnesium oxide, tertiary and secondary sodium phosphate, hydroxides of zinc, aluminium and colloidal iron, and mixtures of primary and secondary sodium phosphates in yeast fermentation of sucrose. All the substances added were without effect on yeast invertase. The reaction in each instance occurred according to the equation: $2C_6H_{12}O_6 + H_2O = CH_3COOH + C_2H_5OH + 2CO_2 + 2C_3H_5O_3$. Acetic acid and glycerin were formed in the ratio of 1:2 mols. Hydroxides of aluminium and colloidal iron had no special effect on fermentation. The results in general support the theory previously advanced concerning sugar fermentation in presence of alkaline salts.—*W. W. Bonns.*

803. NEUBERG, C., und J. HIRSCH. Wirkungsweise der Abfangmethode bei der Acetaldehyd-Glycerin-Spaltung des Zuckers. Die Korrelation von Acetaldehyd und Glycerin innerhalb der gesamten Gärführung, der zeitliche Verlauf dieser Vergärungsform und ihre Beziehung zur gewöhnlichen alkoholischen Gärung. [The mechanism of the "fixation" method in the acetaldehyde-glycerine cleavage of sugar. The correlation of acetaldehyde and glycerine during the entire fermentation, the time factor in this process and its relation to ordinary fermentation.] *Biochem. Zeitschr.* 98: 141-158. *Fig. 1-4.* 1919.—The writers review the work of the senior author and others in which by means of "fixation" by alkaline salts acetaldehyde and glycerine are established as definite stages in the yeast fermentation of sugar. Such fermentations are grouped into: (1) The usual alcoholic fermentation ($C_6H_{12}O_6 = 2C_2H_5OH + 2CO_2$); (2) acetaldehyde-glycerine fermentation ($C_6H_{12}O_6 = CH_3CHO + CO_2 + C_3H_5O_3$); (3) Acetic acid-ethyl alcohol-glycerine fermentation ($2C_6H_{12}O_6 + H_2O = C_2H_5OH + CH_3COOH + 2CO_2 + 2C_3H_5O_3$). The present work seeks to determine the acetaldehyde-glycerine relations during the process, their rate of formation and the relation of this type to the ordinary alcohol- CO_2 fermentation. It was found that at every stage during the fermentation in the presence of sodium sulphite acetaldehyde and glycerine are formed in equimolecular quantities. At the same time, ethyl alcohol and CO_2 are produced independently and in equivalent proportions. The stage of fermentation can thus be determined from the amount of alcohol or aldehyde present.—*W. W. Bonns.*

804. OSTWALD, W. Physikalisch-chemische Bemerkungen zu Neuberg's Gärungstheorie. [A physico-chemical consideration of Neuberg's fermentation theory.] *Biochem. Zeitschr.* 100: 279-288. 1919.—In this critical discussion of the work of Neuberg and others [see *Bot. Absts.* 7, Entries 1344, 1345] the writer, while accepting in general the former's fermentation theory, ventures to differ in the interpretation of some of the intermediate reactions in the process, basing his arguments on physico-chemical grounds.—*W. W. Bonns.*

805. TSCHERIKOWSKI, SALOMO AL. *Beitrag zur Kenntnis der Zellfermente.* [Cell enzymes.] Dissertation. 12 p. Berlin and Leipzig, 1921.—The author repeats the work of Abderhalden on specificity of cell enzymes. Using enzyme extracts from liver, muscle, spleen, and kidneys of rabbits, horses, and calves, and a peptone from each of the same organs he followed the hydrolysis of the peptone optically. He found that the kidney extract hydrolyzed all the peptones prepared, whereas the extracts from liver, muscle, and spleen were specific for the peptones from their respective organs. There was no 'species' specificity demonstrated.—A. F. Camp.

806. WOKER, G. *Zur Theorie der Diastasewirkung.* [The theory of diastase action.] *Biochem. Zeitschr.* 99: 307-315. 1919.—This is a critical discussion and defense of the author's previous work, replying to the criticism of Wohlgemuth [see Bot. Absts. 8, Entry 651].—W. W. Bonns.

METABOLISM (RESPIRATION, AERATION)

807. MORSE, STERNE, and NICHOLAS KOPELOFF. *A simple method for anaerobic cultivation in Petri dishes.* *Amer. Jour. Public Health* 12: 119-121. *Fig. 1-3.* 1922.—Two Petri dish bottoms or covers of the same diameter are used. The culture or medium is poured and allowed to harden. It can then be streaked in the usual way. The paired dishes are then turned over and 5 to 10 gm. dry pyrogallic acid placed in the now lower half. About 30 cc. of a 5 per cent solution of sodium hydroxide is quickly poured over the pyrogallic acid. A strip of adhesive tape is immediately placed around the equator thus uniting the halves. The resulting "capsule" is then incubated and treated with no more respect than an ordinary aerobic plate. In order to maintain the condition of anaerobiosis for a long time it is only necessary to varnish the tape. The authors claim for the method that it is simple, inexpensive, efficient, easy to manipulate, and does not require other than stock apparatus.—C. A. Ludwig.

ORGANISM AS A WHOLE

808. DIXON, GUERNEY. *The transmutation of bacteria.* 179 p. Cambridge University Press: Cambridge, 1919.—Aside from certain cultural experiments the book is essentially a review and discussion, from the standpoint of possible transmutation of species, of the literature dealing with morphological and physiological variations in the species of bacteria. The author concludes that while incapable of proof, the transmutation of allied organisms in the human body is suggested but that supposed instances of transmutation experimentally induced rest on inconclusive evidence. An extensive bibliography is included.—C. C. Epling.

809. EULER, H., and J. LAURIN. *Zur Kenntnis der Hefe Saccharomyces Thermantitonum.* [Concerning the yeast *Saccharomyces Thermantitonum.*] *Biochem. Zeitschr.* 97: 156-169. 1919.—This is a discussion of experiments with the above organism dealing with optimum growth conditions, rate of fermentation, inversion capacity, catalase activity, and the effects of acidity and of antiseptics.—W. W. Bonns.

810. GAMBLE, F. W. *Studies in symbiosis.* [Rev. of: BUCHNER, P. *Tier und Pflanze in intrazellulärer Symbiose.* (Plants and animals in intracellular symbiosis.) xi + 462 p., 2 pl. Gebrüder Borntraeger: Berlin, 1921.] *Nature* 109: 538-539, 570-577. 1922.—The 1st part deals with algal associations in lower animals, the 2nd with symbiosis in insects, and the 3rd with bacteria as related to luminosity.—O. A. Stevens.

811. GREENBAUM, SIGMUND S. *On the biologic properties of pathogenic molds.* *Jour. Infect. Diseases* 31: 26-31. 1922.—The author points out the customary neglect of the biologic properties of the higher fungi in most mycological and bacteriological treatises and outlines. This is a study of several pathogenic forms from the standpoint of proteolytic and amylolytic ferments, their actions on various sugars and litmus, indol production, and the production of toxins. Briefly, it was found that while a proteolytic ferment, varying in solubility with

the organism, is common to all pathogenic molds studied, no amylolytic properties were demonstrable. They neither produce acids nor bases nor ferment saccharose, dextrin, glucose, levulose, maltose, or lactose. Two Tricophytons (*T. acuminatum* and *T. gypseum-asteroides*) as well as *Achorion Schoenleinii* were found to elaborate toxins fatal to guinea pigs.—*R. V. Allison.*

812. JORDAN, E. O., and W. B. SHARP. The serologic relationships between strains of the Pfeiffer bacillus. *Influenza studies X.* Jour. Infect. Diseases 31: 198-208. 1922.—In attempting to establish the essential nature of the various strains of the Pfeiffer bacillus it was found that, as a rule, each strain of the organism possessed a serologic individuality. Likewise, no correlation was found between indol production and agglutinative affinities except in strains isolated from meningitis. The inability to group the strains of this organism serologically is accepted as an argument against the assignment of any of its members to the primary causation of epidemic influenza. It is suggested that perhaps a race of "influenza-meningitis" bacilli is in process of evolution.—*R. V. Allison.*

813. KOSER, STEWART A. Development of Paratyphoidenteriditis group in various food-stuffs. Jour. Infect. Diseases 31: 79-88. 1922.—In the study of several type strains of the paratyphoid-enteriditis group in their ability to develop in miscellaneous food stuffs it was found that strains from the Gaertner group multiplied readily in the juices of many cooked vegetables but were rapidly destroyed in the juices of different fruits as well as in the acid liquor of sauerkraut. There was also observed a marked ability of the organism to spread through food stuffs but only under conditions of optimum temperature. It was also found that the development of the Gaertner group in food stuffs is not usually accompanied by visible alteration or spoilage.—*R. V. Allison.*

814. LAPICQUE, LOUIS, et THÉRÈSE KERGOMARD. Changements dans la réaction de l'eau douce sous l'action des plantes aquatiques. [Changes in the reaction of fresh water under the influence of aquatic plants.] Compt. Rend. Soc. Biol. 87: 512-515. 1922.—Experiments were performed with the following plants: *Spirogyra*, *Potamogeton*, and *Elodea*. One gm. of fresh material was placed in 50-100 gm. water. The pH of the water (either from the Seine or from a spring) was determined colorimetrically at regular intervals. In the dark the alkalinity diminished and sometimes the water became rather acid. In the light the opposite phenomenon occurred, the alkalinity of the water rising from an initial pH value of 7.2-7.6 to 9-10. The mechanism of this change of reaction is obvious: it depends on the antagonism between the respiration of the plant liberating CO₂ and the assimilative processes of chlorophyll.—*S. Morgulis.*

815. MOORE, BARRINGTON. Influence of certain soil factors on the growth of tree seedlings and wheat. Ecology 3: 65-83. 6 fig. 1922.—A series of experiments was made at Mt. Kisco, New York, to learn the effect of soils, especially alkaline soils, on natural vegetation. The soils used were glacial quartz sand, pure humus, and mixtures of the sand and humus. The wilting coefficients of these soils in moisture retention tests were 0.85, 43.5, and 2.4 per cent respectively. In the alkalinity tests the same soils were used with addition of 2, 4, and 6 per cent (by volume) of burnt lime, calcium oxide. Another series of soils with a lower admixture of lime was also used and all the soils were titrated for alkalinity. In seed-flats of these soils, red maple seedlings, and seed of wheat, *Pinus resinosa*, *P. Banksiana*, *P. rigida*, and *Thuja occidentalis* were planted. Seed of *Pinus Strobus* were also planted but did not germinate well enough to give results. Eight tables give the data in concrete form. Considering tops and roots, humus gave better results than sand or mixtures of sand and humus. It is assumed that the results with humus are due to the nitrogen content. Pine species, wheat, and *Thuja* responded favorably to humus in the order named. In the more alkaline soil series all plants died rapidly or eventually except *Thuja* and wheat, the 2 last named growing exceptionally well on the series with less lime. On the whole, it is held that slight alkalinity in the soil is far more toxic to plants than the same degree of acidity.—*H. H. M. Bowman.*

816. PHILIBERT, ANDRE, et GEORGES MATHIEU. **Nouveau procédé de l'analyse qualitative des eaux.** [A new procedure of qualitative examination of waters.] *Compt. Rend. Soc. Biol.* 86: 1004-1006. 1922.—The method depends on the addition of lead subacetate to the medium which contains 6 per cent peptone and 2.4 gm. phenol per l. The tubes with the water under examination are kept for 48 hours at 41°C. (1) The tubes which give the indol reaction contain *B. coli*. (2) Those which are blackened, but do not give the indol test, contain putrefying organisms other than *B. coli* or *B. proteus*, probably *para B.* (3) Those which turn black and give the indol test and turn gelose-lactose-litmus red contain *B. coli*, while (4) those which produce blue cultures contain *B. proteus*.—*S. Morgulis*.

817. RAMSBOTTOM, J. **Orchid mycorrhiza.** *Gard. Chron.* 71: 95-96. 1922.—This consists of brief notes on the symbiotic relation.—*P. L. Ricker*.

818. RAYNER, M. C. **Notes on mycorrhiza plants.** *Gard. Chron.* 71: 102, 152. 1922.—Notes are given on the symbiotic relation between fungous hyphae and beech, heaths, orchids, and various other plants.—*P. L. Ricker*.

819. TANNER, FRED W., and GAIL M. DACK. ***Clostridium botulinum*.** *Jour. Infect. Diseases* 31: 92-100. 1922.—Numerous soils as well as samples of feces and sewage were examined in the study of the distribution of *C. botulinum*. The results support, in general, the conclusions of Meyer and Geiger, who suggest the probability of regional distribution. The different strains of *Clostridium* studied were found to exhibit marked variations in their ability to resist dry heat.—*R. V. Allison*.

820. TORREY, JOHN C., and GEORGE T. BUCKELL. **Cultural methods for the *Gonococcus*.** *Jour. Infect. Diseases* 31: 125-147. 1922.—In the discussion of the media employed, special consideration is given the value of amino acids, moisture, reduced oxygen tension, and growth-stimulating substances. Besides presenting the comparative results of the several media used, suggestions for the primary isolation of the organism as well as the maintenance of the stock strains are included. Criteria for the identification of the *Gonococcus* are outlined and fermentation tests for the differentiation from other similar Gram-negative diplococci are emphasized.—*R. V. Allison*.

821. WRESCHNER, HANS. **Untersuchungen über die biologische Bedeutung der Kapsel beim *Micrococcus tetragenus*.** [The biological significance of the capsule in *Micrococcus tetragenus*.] *Zeitschr. Hygiene u. Infectiouskr.* 93: 74-86. 1921.—Successive agar transplants of *Micrococcus tetragenus* showed a gradual decrease in capsule formation and virulence for white mice. In this way a capsule-free strain was isolated and compared with the capsulated culture. The former gave positive phagocytic and complement-fixing reactions. The analogy is drawn between the specific action of the capsule and that of a dialyzing membrane which protects the cell from the entrance of serum antibodies.—*W. H. Chambers*.

GROWTH, DEVELOPMENT, REPRODUCTION

822. BARTHOLOMEW, E. T. **Acid and water content of lemon fruits at different stages of development.** [Abstract.] *Phytopathology* 12: 107. 1922.

823. BAULE, B. **Prinzipielle Überlegungen zum Wachstumsgesetz der Pflanze.** [Considerations of the law of growth of plants.] *Landw. Jahrb.* 54: 493-506. 4 fig. 1919.—This is a discussion of physiological and mathematical aspects of Mitscherlich's equation for the growth of plants. The amount of growth made at any given time must be an integration of all factors up to that time. The course of the growth is determined by a purely time-function, but its limits are set by the life-duration of the plant. The growth law reflects in the size of the plant many changes in growth conditions during the growth period of the plant. The conditions in the middle of the grand period of growth are especially important. The absorption of nutrients appears to be so modified during the growth period that the effect

is a maximum, or, to state it in another way, the materials used in forming plant substance are the least possible.—*H. S. Reed.*

824. FISCHER, HUGO. Beitrag zur graphischen Auswertung der Wachstumserscheinungen bei Pflanzen. [The graphical determination of growth phenomena in plants.] Zeitschr. Forst- u. Jagdw. 51: 527-534. Fig. 1-5. 1919.—The relation of growth of a rye culm to the factors of atmospheric temperature and soil moisture is plotted. By plotting lengths of the culm as ordinates over the time of each measurement as abscissae a figure S is obtained, which the author is convinced will represent the growth of any single plant or any plant organ. In comparing a temperature curve with the curve of actual growth superimposed on the normal curve, it is found that checked growth coincides with increased temperature, and vice versa. The same result is encountered in the influence of precipitation on growth. In other words, the apparent paradox is due to the fact that the favorable or unfavorable effects of temperature and moisture on plant growth are not immediately felt, but are expressed by the plant during the following period, which varies directly in length with the length of the period during which the favorable or unfavorable condition continued.—*J. Roeser.*

825. KONINGSBERGER, V. J. A method of recording growth under various external influences. Proc. Roy. Acad. Sci. Amsterdam [translated from Verslag K. Akad. Wetenschappen Amsterdam] 23: 783-789. 1921.—The paper describes in detail a sensitive and improved form of auxanometer in which the plant carrying a very weak electric current and a contact makes and breaks the circuit, which by means of a relay controlling a stronger current, operates the recording apparatus. The time required for a definite growth increment is recorded.—*L. Knudson.*

MOVEMENTS OF GROWTH AND TURGOR CHANGES

826. ANONYMOUS. Plant sensitiveness. Gard. Chron. 71: 283. 1922.—Comments are made on a recent lecture by Keeble at the Royal Institute, in which the writer mentions many new facts on plant movements that have been discovered since Darwin's work and suggests the need of a new work on this subject brought up-to-date.—*P. L. Ricker.*

827. KONINGSBERGER, V. J. Tropismus und Wachstum. [Tropism and growth.] Recueil Trav. Bot. Neerland. 19: 1-136. 3 pl., 17 fig. 1922.—A new method of automatic registration of growth is described whereby measurement is made (1) in complete darkness and (2) during rotation with the clinostat. The auxanometer is located in the room where the experiments are conducted, whereas registration may be made in an adjacent room. The coleoptils of *Avena* in darkness show their highest range of growth upon having reached a height of between 31 and 37 mm. (average 34 mm.). The first green leaf was light insensitive; even an illumination of 90 M.K. had no influence. When plants were put in darkness after 5 hours of illumination no reaction occurred. Observing various growth curves under the influence of light, it is found that in all cases fluctuations ensue. The behavior of "rapidity of growth" and "susceptibility to light" is not a parallel effect.—*J. C. Th. Uphof.*

828. MEADE, R. M. Positions and movements of cotton leaves. Jour. Heredity 12: 444-448. 2 pl., 1 fig. 1921.—The leaves of *Gossypium hirsutum* move definitely in direct reaction to sunlight, and similar movements have been observed in other species of *Gossypium*. The leaves are heliotropic, the movement being controlled by pulvini situated at the base of the petiole.—*J. H. Kempton.*

GERMINATION, RENEWAL OF ACTIVITY

829. DARLINGTON, H. T. Dr. W. J. Beal's seed-viability experiment. Amer. Jour. Bot. 9: 266-269. 1922.—In 1879 Beal prepared 20 bottles, in each of which he placed 50 seed of each of 23 plants mixed with moist sand. These he buried deeply in the soil. At 5-year intervals a bottle was taken up and its seed tested for germination. The 8th test was made in the spring of 1920. Eight species germinated and the total percentage of germination was at least 8.2 per cent. This was somewhat better than the test of 5 years ago.—*E. W. Sinnott.*

830. KNOWLTON, H. E. **Studies in pollen, with special reference to longevity.** Cornell Univ. Agric. Exp. Sta. Mem. 52. 751-793. 1922.—For the experiments reported, pollen of *Antirrhinum majus* L. and that of *Zea Mays* L. were used. The former is long-lived; the latter short-lived. *Antirrhinum* pollen remained viable and capable of germination for 670 days, but the fertilizing power was retained for only 161 days. Death of *Antirrhinum* pollen is not due to desiccation, exhaustion of food material, or to loss of enzymes. Corn pollen is high in moisture content and the chief carbohydrate is starch. It remains viable for a period only of 1 or 2 days. One cause of death of corn pollen is loss of water, but this is not the only one. Protoplasmic changes must be involved in the death of both kinds of pollen. Many data are reported in the relation between various conditions of storage and viability.—L. Knudson.

TEMPERATURE RELATIONS

831. HARVEY, R. B. **Varietal differences in the resistance of cabbage and lettuce to low temperatures.** Ecology 3: 134-139. 6 fig. 1922.—It is desirable (1) to extend the range of crop plants by finding varieties which can withstand lower temperatures than the species in general and (2) to find varieties which can be hardened to low temperatures. The writer experimented with several varieties of cabbage and lettuce to find which ones might extend northward the range of these vegetables in winter culture. Among the cabbages the red varieties do not freeze so quickly as the green ones when the plants are placed in constant-temperature chambers equipped with refrigeration and electric thermal control apparatus. Many varieties of cabbage, both red and green, can easily withstand low temperatures after the plants have been hardened by exposure to low temperatures for varying periods. In lettuce, likewise, the writer finds that the different commercial varieties tested show great differences in the degrees of hardiness. A high sugar content of the leaves does not render the plants less susceptible to freezing, and hardiness seems to depend rather upon differences in the protein constituents of the cells.—H. H. M. Bowman.

832. MAGNESS, J. R. **Chemical and physiological studies of fruit storage.** Proc. Amer. Soc. Hort. Sci. 18: 169-172. 1921 [1922].—This paper presents a discussion of some of the work under way at the Marble Laboratory, Inc., especially that of the life conditions of the apple in storage.—W. E. Whitehouse.

RADIANT ENERGY RELATIONS

833. HARDER, RICHARD. **Lichtintensität und "chromatische Adaptation" bei den Cyanophyceen.** [Light intensity and "chromatic adaptation" in the Cyanophyceae.] Ber. Deutsch. Bot. Ges. 40: 26-32. 1922.—The author found, among 50 species of Cyanophyceae grown in culture, only 2 which showed clearly a color difference when grown in lights of different colors. His experiments were carried out with but 1 of these (*Phormidium foveolarum*). Boresch's results [Ber. Deutsch. Bot. Ges. 37: 1919] were confirmed. The more intense the colored light to which the cultures were exposed the more quickly the adaptive coloration resulted. In weak monochromatic light no change in coloration took place even though in some cases the illumination was sufficient to permit considerable growth. The author calls attention to the differences in coloration in Cyanophyceae induced by different intensities of white light, and he attributes largely to the intensity factor the various colors often exhibited by a given species growing in different locations out-of-doors or by different parts of a single filament.—Richard Holman.

834. HEILBRONN, A. **Das Wesen der Lichtperzeption höherer Pflanzen.** [The nature of light-perception in the higher plants.] Sitzungsber. Naturhist. Ver. Preussisch. Rheinlande u. Westfalens 1919: B15-B18. 1920.—A report is here given of a paper presented at a meeting of the Medical and Natural History Association of Münster, Germany, held in December, 1919. The author discusses the question whether plants perceive the direction of light or differences in light intensity, in connection with their heliotropic movements. Although he reaches no definite conclusion, he inclines to the opinion that the direction of the light is the more important factor in the process.—A. W. Evans.

835. NIENBURG, WILHELM. Die Keimungsrichtung von Fucoseiern und die Theorie der Lichtperzeption. [The direction of germination of *Fucus* eggs and the theory of light perception.] Ber. Deutsch. Bot. Ges. 40: 38-40. Fig. 1. 1922.—Such light as may penetrate the *Fucus* egg is rendered diffuse by the presence of the oil drops and fucosan and chlorophyll grains. Hence the author has used the eggs of *Fucus serratus* in an attempt to show whether light direction or differences in light intensity determine the direction of plant reactions to light. As is well known the rhizoid arising on germination of the egg is formed normally on the unilluminated side. In his experiments illumination was from below in such manner that in many cases $\frac{1}{2}$ of each fertilized egg was in the light, the other in darkness. In such cases the rhizoid always arose from the shaded portion and grew at right angles to the direction of the illumination. Fully illuminated eggs formed rhizoids on the side away from the light, growing parallel to its direction; and eggs entirely in the dark developed rhizoids in all directions. The author interprets these results to indicate that it is not light direction but difference in light intensity that determines the direction of germination in the structures studied.—R. M. Holman.

836. WIESSMANN, H. Einfluss des Lichtes auf Wachstum und Nährstoffaufnahme bei verschiedenen Getreidegattungen. [Influence of light on the growth and absorption of nutrients in various genera of grains.] Landw. Jahrb. 56: 155-168. 1921.—Summer rye, barley, and wheat were grown with the same fertilizers but some in the dim light of a court, others in direct light. Those in the dim light yielded less dry matter than those in strong light. The straw of those grown in dim light contained higher percentages of nitrogen, phosphoric acid, and potash than did those grown in strong light.—A. J. Pieters.

TOXIC AGENTS

837. BOAS, FRIEDRICH. Die Wirkung der Saponinsubstanzen auf die Hefezelle. [The effect of saponin substances upon yeast cells.] Ber. Deutsch. Bot. Ges. 40: 32-38. 1922.—The author has measured the carbon dioxide production of yeast cultures containing in each case, in addition to cane sugar and distilled water, 1 of the following: Quillayasaponin, sapotoxin, saponin (Merck-principally quillayasaponin), smilacin, digitonin and guajaksaponin. Among the cultures containing each saponin substance were those also containing either sodium nitrate, sodium chloride, lithium chloride, or magnesium nitrate. Controls with distilled water, with water and sodium nitrate, and with water and lithium chloride were also included. From the results of these experiments the author concludes that highly active saponin substances and such digitonin and smilacin as reduce fermentation injure the yeast cells by reason of the great change which they induce in the colloidal condition of the lipid; whereas the other saponin substances employed, which cause an increase in fermentation in solutions with little or no salts present, alter the colloidal condition of the lipid to a lesser degree and increase permeability without causing injury to the cell. He believes that his results taken together with those of R. Collander, Hansteen-Cranner, and Kahlos may be considered as establishing the truth of the lipid theory of permeability.—R. M. Holman.

838. COBET, R. Ueber den Einfluss der arsenigen Säure auf wachsende Gewebe. [The effect of arsenious acid on growing tissues.] Biochem. Zeitschr. 98: 294-313. 1919.—Solutions of arsenious acid and of arsenic salts proved toxic at dilutions of 1: 200,000 to roots of garden cress, onions, and peas. No growth stimulus at lower concentrations was established. Frog spawn and tadpoles were more resistant, requiring as a lethal dose concentrations of 1: 40,000.—W. W. Bonns.

839. JONESCO-MIHAESTI, et C. POPESCO. L'influence de la concentration en ions H sur le développement et la production de toxines par le bacille de Shiga. [Influence of H-ion concentration on the development and toxin production of the Shiga bacillus.] Compt. Rend. Soc. Biol. 86: 893-895. 1922.—The range of H-ion concentration within which *B. Shiga* develops is from pH 5.4 to pH 9.1, with the optimum concentration at pH 7.1. The produc-

tion of toxin was studied within a pH range of 7.3–8.5 and the maximum values for 24 hours were obtained at a pH of 7.5. At the end of 18 days the toxicity of all the cultures was the same.—*S. Morgulis*.

840. MÜLLER, A. Ist das unzersetzte Wasserstoffsperoxyd oder der aus ihm abgespaltene Sauerstoff Träger der Desinfektionswirkung? [Is the disinfecting action of hydrogen peroxide due to the whole molecule or to the oxygen split from it?] Zeitschr. Hygiene u. Infektionskr. 93: 348–371. 1921.—The disinfecting power of hydrogen peroxide and of hydrogen peroxide plus catalase was tested on *Bacterium coli* and *B. prodigiosum*. The disinfecting action of the hydrogen peroxide was attributed to the whole molecule, for the addition of catalase was inhibitory. The difference between endocatalase and ectocatalase in protecting the bacteria from hydrogen peroxide was studied. The H-ion concentration affected the reactions essentially according to its influence on the catalase.—*W. H. Chambers*.

841. PANISSET, L., et J. VERGE. Action de l'hyposulfite de soude sur le développement des microbes. [The influence of sodium hyposulphite on the development of microbes.] Compt. Rend. Soc. Biol. 86: 848. 1922.—A 1 per cent solution of sodium hyposulphite added to peptone media has no effect on the growth of various germs. A 2 per cent solution has a slight effect on some organisms, and even a 5 per cent solution leaves some pathogenic organisms unaffected.—*S. Morgulis*.

Public Health 12: 608–614. 1922.—The amount of toxin produced by the diphtheria bacillus is shown to be dependent upon the peptone used for several generations previous to the use of the culture for toxin production.—*C. A. Ludwig*.

PHYSIOLOGY OF DISEASE

844. HOPKINS, E. F. Hydrogen-ion concentration in its relation to wheat scab. Amer. Jour. Bot. 9: 159–179. 18 fig. 1922.—The relation of H-ion concentration to the growth of *Gibberella Saubinetii*, the causal organism of wheat scab, and to the ability of this fungus to produce infection in wheat was studied. The pathogen was grown (a) on liquid media the reaction being adjusted in 1 case by H_2SO_4 and NaOH and in another by phosphate solutions, and (b) on agar, adjusted by lactic acid. In each case, a distinct minimum point in the growth curve occurred at from pH 5.5 to pH 6.0. The fact that various reagents were used shows that this minimum was due to H-ion concentration and not to other molecules or ions. Seedlings were then grown in infected soil, the pH of which was controlled by H_2SO_4 and NaOH, and by HCl and NaOH. The degree of infection was here found to have a definite minimum at about pH 5.5. There is evidence from control series that the soil acidity also affects the rate of seed germination. The practical importance of these relations between acidity and wheat scab is pointed out.—*E. W. Sinnott*.

848. ANONYMOUS. A note on soil sterilization for tomatoes. Bur. Bio-Tech. Bull. 5. 134-142. 1922.—The importance of destroying malignant organisms in the soil and leaving the benign ones is discussed. A report of the use of dichlorocresol and cresol mixed with soap, dichlorocresol absorbed in basic slag and *p*-toluene sodium sulpho-chloramide for soil treatment is given. Dichlorocresol seems to stimulate growth.—W. H. Tisdale.

849. BAL, D. V. Studies on the decomposition of some common green-manuring plants at different stages of growth in the black cotton soil of the Central Provinces. Agric. Jour. India 17: 133-151. 1922.—Experiments on the decomposition of sunn-hemp (*Crotalaria juncea*) and dhaincha (*Sesbania aculeata*) at various stages of growth are described.—A. Howard.

850. BECHHOLD, H. Ein Kapillarphänomen. [A capillary phenomenon.] Kolloid Zeitschr. 27: 229-233. 1920.—The great concentration of salts in the upper layers of a porous structure, such as soil, brick, or unglazed porcelain, when the salt solution evaporates at the surface, is briefly discussed. The mechanism is not clear since when crystallization occurs the upper layers will be saturated while those below may contain undetectable amounts of the salt.—H. E. Pulling.

851. BROWN, P. E., and J. H. STALLINGS. Inoculated legumes as nitrogenous fertilizers. Soil Sci. 12: 365-407. 1921.—Clover or alfalfa were grown in both sterilized and unsterilized soil in pots, a part of the pots being inoculated with nitrogen-fixing bacteria. The nitrogen content of the tops and the roots was determined by the Kjeldahl method. From 12 to 25 cgm. of nitrogen was fixed per plant by clover and alfalfa on untreated soils. On the average 27 per cent of the total plant nitrogen was in the roots of clover at maturity under natural soil conditions, while with alfalfa 46 per cent of the total nitrogen was in the roots. With clover and alfalfa all the nitrogen in the tops and some of that in the roots came from the air. When clover and alfalfa are grown and the hay crops removed there may be some gain in the nitrogen in the soil, the amount of increase varying with the legume, soil type, inoculation, and general conditions.—W. J. Robbins.

852. BURGESS, P. S. Studies on a drained marsh soil unproductive for peas. Univ. California Publ. Agric. Sic. 4: 339-396. 21 fig. 1922.—The author reports field trials and pot cultures to ascertain the best treatments for promoting growth of peas, and includes extensive studies on the chemistry of an unproductive soil. An attempt was made to ascertain the rates of formation and the absolute amounts of soluble salts formed in the soil by various treatments. Calcium carbonate added to neutrality greatly increased nitrate production, while soluble phosphorus and potassium compounds, without lime, produced no effect. In the field, where drought conditions existed, the application of 1 ton of acid phosphate per acre produced an increase, while liming to neutrality did not increase the growth of peas over that of the check plots. In greenhouse cultures, applying lime or acid phosphate materially increased the amount of dry matter. A periodic study of the H-ion concentration showed that all of the soils to which neutral salts had been added were slightly but consistently less acid than the checks and that the H-ion concentration was notably lowered by acid phosphate. All the

compounds increased the concentration of the soil solutions under the growing crops in comparison with the untreated checks. Gypsum increased the solubility of potassium and magnesium. Calcium carbonate increased the solubility of all ions except potassium. The production of root nodules was inhibited by the applications of nitrates or of calcium carbonate. The addition of soluble phosphorus increased nodule formation, but potassium sulphate and gypsum were without effect.—*H. S. Reed.*

853. CHRISTENSEN, H. R. *Undersøgelser over Jordens stofomsaettende Evne og disses Betydning for Jordbunsforskningen.* [Investigations of the power of change of soils and its importance for soil science.] Nordisk Jordbrugsforskning 1921: 200-207. 1921.—The quantitative methods of bacteriological analysis indicated by Remy have proved very useful. Modified by the author by adding to the soil extract the active species of bacteria, they have gained importance for chemical soil analysis. A new series of experiments has shown that soils which are basic or close to the neutral point, and which show a considerable buffer action, not only give *Azotobacter* development in inoculated mannite solutions, but also break down mannite much more vigorously than the soils lacking in buffer action, *i.e.*, the soils which require lime. For the soils not needing lime a correlation is shown between phosphate content and mannite decomposition, determined, not by the microflora, but by the chemical composition of the soil. Most important is the content of basic Ca-compounds and of easily soluble phosphates. Comparison with field tests have shown this correlation to be promising for a laboratory investigation of the need of phosphate in soils. Only soils of basic reaction and with a certain buffer action have a considerable content of CO_2 -soluble phosphates.—*Ernst Gram.*

854. EMERSON, PAUL. *The colorimetric determination of soil in a colored water extract.* Soil Sci. 12: 413-417. 1921.—By decolorizing with aluminium hydroxide, nitrates can be determined by the phenoldisulfonic acid method in soil extracts colored by soluble organic matter. The method is rapid and accurate.—*W. J. Robbins.*

855. ERDMAN, L. W. *The effect of gypsum on soil reaction.* Soil Sci. 12: 433-448. 1921.—Pot experiments in which gypsum was added in amounts from 100 to 2000 pounds per acre to an acid soil, neutral soil, and basic soil did not increase or correct the acidity as shown by the Tacke lime-requirement method. At the rate of 100, 200, and 500 pounds per acre it did not affect the pH of the soil; 1000 and 2000 pounds per acre increased the pH 0.21 and 0.28 respectively in an acid soil, 0.14 and 0.27 in a neutral soil, and 0.09 and 0.12 in a basic soil. Gypsum added at the rate of 500 pounds per acre to a neutral soil, made to vary in degrees of acidity by the addition of hydrochloric acid and calcium carbonate, did not affect the pH or lime requirement.—*W. J. Robbins.*

856. GAINNEY, P. L., and H. W. BATCHELOR. *Influence of H-ion on growth of Azotobacter.* Science 56: 49-50. 1922.—The maximum concentration permitting growth was found to be pH 5.9-6.0 for all strains isolated. At pH 6.1-6.4 growth was quite as vigorous as at lower values.—*C. J. Lyon.*

857. GREAVES, J. E. *Influence of salts on bacterial activities of soil.* Bot. Gaz. 73: 161-180. 1922.—In experimenting with the effect of soluble salts applied to soil upon the production of ammonia, nitrates, and soluble and organic phosphorus, it was found that these salts were toxic to bacteria, partly because of osmotic disturbances. That this is not the entire cause, however, was shown by the fact that there is an antagonistic effect of certain salts when applied together. The results therefore indicate that the toxicity of soluble salts toward soil microorganisms is due to an osmotic effect which makes it impossible for the cell to take up its normal nutrients, but permits foreign or unbalanced constituents to enter. The foreign or unbalanced salts interact with the cell proteins, forming foreign proteinates and thus rendering the protoplasm incapable of normal functioning. Many of these salts when applied in small quantities increased bacterial activities.—*I. V. Shunk.*

858. JONES, J. S., and J. C. REEDER. **The use of silica crucibles for the determination of potassium in soils.** *Soil Sci.* 12: 419-432. 3 fig. 1921.—By the use of an electric furnace and silica crucibles potassium can be determined accurately, thus eliminating the use of platinum.—*W. J. Robbins.*

859. KAPPEN. **Bodenazidität und Kalkdüngung.** [Soil acidity and liming.] *Mitteil. Deutsch. Landw. Ges.* 37: 660-663. 1922.—In this address the writer explains the causes of various forms of soil acidity, the relation of soil adsorption to acidity, the formation of injurious aluminum and iron salts, and the effect of physiologically acid fertilizers. The bad effect of soil acidity on the physical structure of the soil is pointed out. As remedies it is advised to abstain from the use of such fertilizers on acid soils and to apply instead lime as carbonate or oxide.—*A. J. Pieters.*

860. KILIBNGER, A. **Wie verhalten sich schwefelsaures Ammoniak und Salpeter im Boden?** [What becomes of sulphate of ammonia and saltpeter in the soil?] *Mitteil. Deutsch. Landw. Ges.* 37: 353-354. 1922.—The author points out that the excess of the sulphate of ammonia is held by the colloids in the upper soil layers while excess of saltpeter is lost.—*A. J. Peters.*

861. KRAUS, W. **Weitere Untersuchungen über das Bechhold'sche Kapillarrphänomen.** [Further investigations of Bechhold's capillary phenomenon.] *Kolloid Zeitschr.* 28: 161-166. 1921.—Bechhold noted [see *Bot. Absts.* 12, Entry 850] some experiments on the accumulation of salt crystals at evaporating surfaces of porous bodies that contained aqueous salt solutions. The author finds: evaporation is necessary for the accumulation; drying occurs as noted by Zsigmondy for the dehydration of silicic acid gel, *i. e.*, it takes place at the surface and not gradually throughout, so the salt accumulates at the surface and there is no gradient of concentration below this layer. If a hydrophilic colloid is added the accumulation takes place only at a higher temperature; decreasing the wetability of the surface decreases the accumulation; in holes in the interior of gypsum the accumulation also occurs; it occurs likewise on filter paper pressed between glass plates with about 1 cm. protruding; also on flat surfaces when the liquid is placed thereon as a drop, but the surface must be wetted by the solution; solutions of high viscosity dry with an equal distribution of the salt, *i. e.*, no accumulation at the surface.—*H. E. Pulling.*

862. LIPMAN, J. G., A. L. PRINCE, and A. W. BLAIR. **The influence of varying amounts of sulfur in the soil, on crop yields, hydrogen-ion concentration, lime requirement, and nitrate formation.** *Soil Sci.* 12: 197-207. 2 fig. 1921.—Inoculated and uninoculated sulphur was applied to plots on which barley and soybeans were being grown at the rates of 200, 500, 1000, 2000, and 4000 pounds per acre. Germination of the barley was fair on all plots, but was markedly depressed in the case of soybeans on plots with 1000 pounds per acre and over. Growth of barley was injured on 1000-pounds plots and over, being nearly all killed by the 4000-pound application. Soybeans showed normal growth with 200 and 500 pounds, but growth was depressed where larger amounts were used. The H-ion concentration did not change throughout the season on the 200- and 500-pound plots, but on the 1000- to 4000-pound plots the H-ion concentration increased after 4-8 weeks. The greatest change was from an initial pH of 5.6 in May to a pH of 3.5 in August on the 4000-pound plot treated with uninoculated sulphur. Applications of 200-500 pounds did not influence the lime requirement, but with heavier applications the lime requirement was decidedly increased. The authors believe that the H-ion concentration may give an approximation of the lime requirement varying with different soils and treatments. The nitrate content appeared to vary considerably showing a fairly close relationship to crop growth, the least amounts being found at the time the crops were matured. The relation between H-ion concentration and nitrate content indicates that nitrification is not generally inhibited by increased acidity of the soil.—*I. T. Scott.*

863. LIPMAN, JACOB G., SELMAN A. WAKSMAN, and JACOB S. JOFFE. **The oxidation of sulfur by soil microorganisms.** *Soil Sci.* 12: 475-489. 1921.—A liquid medium, pH 6.0-6.2

containing mineral salts, including tricalcium phosphate and elemental sulfur, was inoculated with a suspension of a compost in which sulphur oxidation was occurring. The pH of the medium was lowered to 1.2 and the soluble phosphate and sulphate increased. Dextrose interfered with the oxidation of the sulphur. The sulphur-oxidizing bacterium was isolated in pure culture by continual transfer, by dilution, and by using media of high acidity; it could not be grown on solid media. Experiments in liquid media with this bacterium in pure culture showed that there first occurs a rapid increase in acidity accompanied by an accumulation of soluble sulphate. The insoluble phosphate is then made soluble by the sulphuric acid. This change is accompanied by a decrease in soluble sulphate and a stationary phase in the acidity. As soon as all the insoluble phosphate is used up the acidity again increases. In 15 days 93.97 per cent of the insoluble phosphate was dissolved. Using media of different initial pH, best growth was obtained at pH 2.0–2.8. A brief description of the bacterium is given.—*W. J. Robbins.*

864. LYON, T. L., and JAMES A. BIZZELL. **Lysimeter experiments. II. Records for tanks 13 to 16 during the years 1913 to 1917 inclusive.** Cornell Univ. Agric. Exp. Sta. Mem. 41. 47–93. 1921.—The data recorded and discussed were obtained from a study of a Volusia silt loam of Tompkins County, New York, held in concrete lysimeters. (See Cornell Univ. Agric. Exp. Sta. Mem. 12 for a description of these lysimeters.) The soil used is of wide distribution in southern New York and is noted for its need of lime and general lack of fertility. Four lysimeter tanks were utilized, 2 being kept bare continuously while 2 were cropped successively to oats, canada peas, maize, oats, and barley. One bare tank and 1 cropped tank received burned lime at the rate of 3000 pounds per acre at the beginning of the experiment. Manure at the rate of 10 tons an acre was applied to all 4 lysimeters in 1913.—The object of the work was to observe the removal of calcium and certain other constituents from the soil by drainage and cropping. In comparing the bare and cropped tanks, it was found that 82 per cent of the rainfall (average annual precipitation 33 inches) was lost by percolation from the former and only 62 per cent from the latter. The average annual percolation losses in pounds to the acre of nitrogen, calcium, and magnesium from the bare tanks were 52, 356, and 45 pounds respectively. Corresponding data for the cropped lysimeters were 10, 341, and 30. The comparative figures for potash and sulphur from the bare and cropped tanks were of a similar order but much less divergent. Only traces of phosphoric acid appeared in the drainage.—The addition of lime had no effect on the amount of percolation water. Liming seemed to favor nitrification, increasing to a marked degree the nitrogen in the drainage water and in the crops grown. An appreciable percolation increase of calcium was obtained by liming the bare soils. The total amounts of calcium removed from the cropped tanks, limed and unlimed, were identical. The influence of liming upon the magnesium was in the same direction although more total magnesium was removed from the limed and cropped soil than from the unlimed and cropped one. Liming had little effect on the precolation losses of potash, phosphoric acid, and sulphur although such a treatment increased the amounts of these constituents removed by the crops.—*H. O. Buckman.*

865. McCALL, A. G. **The lime requirements of Maryland soils.** Rept. Maryland Agric. Soc. 5: 328–331. 1920 [1921].—A soil testing campaign in Maryland showed that of 1,500 soils 5 per cent showed very strong acidity; 10, strong acidity; 27, medium acidity; 18, slight acidity; 14, very slight acidity, and 26, no acidity. The best form of lime to use is that which supplies the available lime at least cost.—*A. Lee Schrader.*

866. McHARGUE, J. S., and A. M. PETER. **The removal of mineral plant food by natural drainage waters.** Kentucky Agric. Exp. Sta. Res. Bull. 237. 331–362. 1921.—More than 50 samples of water from streams and springs in various parts of Kentucky were analyzed for phosphorus, potassium, nitrate-nitrogen, calcium, magnesium, sulphur, sodium, chlorine, and in a few instances manganese. Drainage water from limestone areas contains the greatest amount of mineral matter and that from sandstone areas the least. The waters from the sandstone areas contain more than twice as much potassium as those from limestone areas while

the amount of phosphorus depends on the amount contained in the soil from which the water flows. A positive correlation between nitrate-nitrogen and soluble phosphorus was found. The total mineral matter in solution in large streams is much less than that contained in small streams flowing from limestone areas. More extensive use of cover crops is advised to conserve much of the mineral nutrients now lost through drainage waters.—*W. D. Valleau.*

867. MATTSON, S. E. Die Beziehungen zwischen Ausflockung, Adsorption und Teilchenladung mit besonderer Berücksichtigung der Hydroxylionen. [The relations between flocculation, adsorption, and the electric charges on particles with special reference to the hydroxyl ions.] *Kolloidchem. Beih.* 14⁹⁻¹²: 227-313. 1922.—Suspensions were made of a fine quartz powder, a plastic clay, and a strongly humus Sphagnum turf and these were treated with hydroxyl-yielding compounds and neutral salts. The hydroxyl ion is extensively adsorbed by soils. Flocculation is not only conditioned by the reduction of the charge on the particles but also by strongly charged particles that have adsorbed a large number of ions. The adsorbed ions act as binding members between particles. Hydroxyl ions are not to be considered as uniquely determining soil structure; those ions that remain in excess in the soil solution are of most importance. The ability of soil to adsorb hydroxyl ions influences the solubility of various compounds and explains the acidity of many soils. Many examples of equilibria involving these principles are worked out and the paper is illustrated with photographs and photomicrographs.—*H. E. Pulling.*

868. MELIN, ELIAS. Ultramikroskopische Mikroben im Waldboden. [Ultramicroscopic organisms in forest soil.] *Ber. Deutsch. Bot. Ges.* 40: 21-25. 1922.—Five hundred gm. of humus from a plantation of *Pinus sylvestris* not far from Berlin was extracted with 750 cc. of distilled water at room temperature for 24 hours. A portion of the extract was concentrated in vacuum to $\frac{1}{3}$ its original volume. Portions of the extract were passed through filters with fine, medium, and coarse pores and then added to culture media containing 10 per cent gelatine, 2 per cent glucose, and a little ammonium citrate or a few drops of bouillon. The filters used were Haën's membrane type. Various bacteria present in the soil passed the coarse filter. The extract passed through the medium filter showed no visible evidence of bacteria or other micro-organisms but caused liquefaction of the gelatine, while the extract passed through the finest filter did not cause liquefaction. The author believes the latter fact to be sufficient evidence that the liquefaction of gelatine by the extract passed through the medium filter was not caused by enzymes present in the soil. The concentrated extracts caused liquefaction much more quickly than those which had not been concentrated.—*R. M. Holman.*

877. REED, J. W. *Practical significance of organic carbon-nitrogen in soils.* *Soil Sci.* 12: 491-495. 1921.—An examination of 37 soils failed to show a correlation between soil productivity and the organic carbon-nitrogen ratio.—*W. J. Robbins.*

878. RELWANI, LOKERAN L. *Kalar reclamation as carried out on the Sukkur Farm.* (Alkali soil reclamation in Sind, India.) *Poona Agric. Coll. Mag.* 12: 117-123. 1921.—The reclamation is difficult because of the heavy texture of the soil. Methods employed include (1) irrigation, with drainage ditches on the lower sides of fields; (2) growing suitable alkali-resistant crops, such as sava (*Panicum stagninum*) for 1-2 seasons; (3) scraping off efflorescent salts where accumulations are pronounced; and (4) plowing and planting to bersim (*Trifolium alexandrinum*), which gives a good stand after 1-2 years.—*Robert L. Pendleton.*

879. ROSSI, GIACONIO. *Preliminary note on the microbiology of the soil and the possible existence therein of invisible germs.* *Soil Sci.* 12: 409-412. 1921.—A decanted extract of fresh soil was filtered through an aseptic Chamberland filter into flasks containing sterile culture media. After incubation the culture liquid was tested for products which might be formed by bacterial action. No evidence of indol production or the formation of nitrites was found.—*W. J. Robbins.*

880. RUSSELL, E. J. *Les micro-organismes du sol dans leurs rapports avec la croissance des plantes. Position actuelle du problème.* [The micro-organisms of the soil in their relation to the growth of plants. Present status of the problem.] *Ann. Sci. Agron. Française et Étrangère* 18: 49-67. 1921.—The author reviews the microbiological work with soil organisms at the Rothamsted station, emphasizing Russell and Hutchinson's protozoan theory to account for the beneficial effect of partial sterilization of the soil. Studies are being made on the rate

of decomposition in the soil of phenol, cresol, naphthaline, toluene, benzene, and other aromatic hydrocarbons, and a beginning has been made in the study of the comparative sterilizing efficiency of various agents and their derivatives. Results show that chloromethylene benzene is more efficient than methyl benzene, which in turn is more efficient than benzene, for 1 group of organisms reported.—*A. B. Beaumont.*

881. SHEDD, O. M. A comparison of the calcium content of some virgin and cultivated soils of Kentucky by an improved method for the estimation of this element. *Kentucky Agric. Exp. Sta. Bull.* 236. 303-330. 1921.—Because of the remarkable results obtained from the use of limestone on the soils of Kentucky, the calcium content of virgin and cultivated soils was studied in order to determine the effect of cultivation on this constituent. An improved method of estimating the total and easily-soluble calcium in soils is described. Tables are given showing the total and easily-soluble calcium in virgin and cultivated surface and subsoils of 10 different soil areas of Kentucky. It appears that cultivation has caused a considerable loss of calcium. The best types of soils usually contain the largest amounts of calcium, phosphorus, sulphur, and manganese, and the poorest the lowest. Many soils were found to be so low in calcium that this deficiency requires consideration.—*W. D. Valleau.*

882. SJOLLEMA, B. Verland tusschen grasgroei, grondwaterstand en slootwater. [Relation between grass growth, ground water, and ditch water.] *Cultura* 34: 81-82. 1922.—The writer presumes that when the Zuider Zee has been drained it will have much influence upon the grass production of neighboring meadows and farm lands. In order to study the height of the ground water, it is advisable to place pipes vertically in the soil on the desired localities so that the height of the water may be measured.—*J. C. Th. Uphof.*

883. TAMHANE, V. A. Investigations into the nature of the salt lands of Sind (India). *Bombay Presidency. Dept. Agric. Bull.* 96. 57 p., 4 pl. 1920.—Much of the surface soil on the right bank of the Indus is medium to heavy textured, but often a sandy subsoil greatly facilitates good drainage. The left bank soils are heavier textured, with a variable tight subsoil. Numerous tables give the chemical composition, the percentages of alkali salts, and the mechanical analyses of the samples studied. In order to prevent new areas from being ruined by surface accumulations of alkali salts, economy in the use of irrigation water is urged. To prevent surface evaporation better tillage methods are advised.—*Robert L. Pendleton.*

884. UNGERER, ERNST. Versuche zur Klärung der Bildung von Schichten in Tontrübungen und deren Verwendung in der Bodenanalyse (zur Ermittlung der Teilchengrösse). [Researches to explain the formation of layers in clay suspensions and their application to soil analysis (to determine the size of particles).] *Kolloidchem. Beih.* 14³⁻⁵: 63-96. 1921.—The author reviews the literature dealing with explanations of this phenomenon. In his own experiments he centrifuged suspensions of ultramarine blue and ultramarine red and removed samples from each distinct layer, the particles of which were counted and measured. From these data and the dry weights of unit volumes of the suspensions, the weights of the individual particles were ascertained. The particles in different strata are decidedly different in size and weight. The size of particles was also determined by observations on the time required for settling and by calculation from Stoke's law. The agreement was good. The time of settling was also determined for a fine clay and for emulsions of gum arabic, various oils, and water. The agreement between observed and calculated diameters is good. From the velocity of migration of a layer and Stoke's equation the characteristic size of particles in the groups that correspond to the different strata can be obtained, and this may be used in soil analysis. Size and weight of particles must be considered as determining the strata which differ markedly from each other. Each layer extends to the bottom of the vessel. The temperature should be constant for good formation of strata. Layers form either in the presence or absence of electrolytes unless the electrolyte has marked coagulating power.—*H. E. Pulling.*

TAXONOMY OF VASCULAR PLANTS

GENERAL

885. ANONYMOUS. [Rev. of: MERRILL, E. D. *A bibliographic enumeration of Bornean plants*. Jour. R. Asiatic Soc. Straits Branch, Special number. 687 p. 1921 (see Bot. Absts. 11, Entry 3553).] Jour. Botany 60: 59-60. 1922.

886. ANONYMOUS. *The Index Kewensis*. [Rev. of: PRAIN, D. *Index Kewensis Plantarum Phanerogamarum*. 5th Suppl. 1909-1915 inc. iii + 277 p. Clarendon Press: Oxford. 1921 (see Bot. Absts. 11, Entry 3199).] Nature 109: 472-473. 1922.—Improvements over earlier volumes are noted in citation of date of publication of books and periodicals referred to and in fuller geographical citations.—O. A. Stevens.

887. ANONYMOUS. [Rev. of: WILDEMAN, E. DE. *Contribution a l'étude de la flore du Katangar*. [Contribution to the flora of Katangar.] viii-cxlv + 264 p. D. Reynaert: Bruxelles, 1921.] Nature 109: 548. 1922.

888. CAÑEDO, JENARO. *Flora de Jalisco y Colima*. [Flora of Jalisco and Colima.] Jalisco Rural [Mexico] 4: 545-547, 619-620, 640-641, 681-682, 703-704. 1922.—Brief popular descriptions are given with the Mexican common names of economic plants of Jalisco and Colima.—John A. Stevenson.

889. CHEESEMAN, T. F. *The vascular flora of Macquarie Island*. Australasian Antarctic Expedition 1911-14. Under the leadership of Sir Douglas Mawson. Sci. Rept. Ser. C.—Zool. and Bot. Vol. VII, Part 3. 4 to., 63 p., 1 map. William Applegate Gullick: Sydney. 1919.—The present publication is based primarily on collections made from December 1911 to November 1913 by Harold Hamilton. Thirty-four species of vascular plants, a number somewhat in excess of previous records, are recorded from Macquarie Island. One species of grass, *Triodia macquariensis* Cheesm., is new to science. Of the 34 species recorded 3 are endemic and not known to occur elsewhere. Of the remaining 31 all but 4 are found in the New Zealand subantarctic islands, and practically one-half of these are circumpolar—occurring in Fuegia or the South Georgia to Kerguelen groups of islands. The author concludes that “the present flora of Macquarie Islands, excepting only the three endemic grasses, does not date further back than the close of the last glacial epoch. Since then, in agreement with the other islands of the subantarctic zone, its history has been a history of plant-migration, mainly from the New Zealand outlying islands, but in some cases from the far-distant Kerguelen group.”—J. M. Greenman.

890. GAUMÉ, JACQUES. [Rev. of: FLORA BATAVA. *Afbeelding in beschrijving der nederlandsche gewassen*. 406°-409° aflevering. The Hague, 1921.] Rev. Gén. Bot. 34: 320. 1922.

891. GEE, N. GIST. [Catalogue of plants of Kiangsu province.] Ko-Hsueh [Science-Publ. Chinese Sci. Soc.] 4: 1117-1124. 1919; 5: 207-212, 603-622, 729-748, 800-814, 1147-1165. 1920; 6: 211-229, 318-335, 417-434, 622-637, 720-733. 1921.—The writer has made a large collection of vascular plants in the province of Kiangsu, China. The present paper is a revised English edition of his first published list with the additional equivalent of a Chinese translation of the botanical descriptions and names by CHUNG-SHU CHIEN. A key in Chinese and in English to families of plants collected is appended.—Chunjen C. Chen.

892. HALES, B. J. **Selected western flora. Manitoba, Saskatchewan, Alberta.** *Small 8 vo., 181 p., 89 fig.* The Macmillan Company of Canada, Ltd: Toronto, 1922.—This work concerns ferns, fern-allies, and flowering plants of that part of North America mentioned in the title. It includes representative species of leading genera of the region, but makes no claim to completeness. It is intended primarily to meet the needs of students of high schools and collegiate institutions of the prairie provinces. A brief key to the families is given, but few keys are inserted for the differentiation of species. The specific descriptions are clear and concise.—J. M. Greenman.

893. HU, HSIEN SU. [A herbarium list of plants of Kiangsi and Chekiang.] Ko-Hsueh [Science-Publ. Chinese Sci. Soc.] 6: 1248-1254. 1921.—This list places on record 152 determined plants of the provinces of Kiangsi and Chekiang, China.—Chunjen C. Chen.

894. HU, HSIEN SU. [The botanical names of Kiangsi plants.] Ko-Hsueh [Science-Publ. Chinese Sci. Soc.] 6: 1144-1171, 1232-1247. 1921. [Text in Chinese.]—A list of botanical names for 518 species of vascular plants collected in the province of Kiangsi, China, is presented with the equivalent Chinese names in characters. The localities where the plants were collected are also recorded.—Chunjen C. Chen.

895. JATUL, P. A. **Mažas Botaniškas Žodynėlis. Dalis I. Augmenu Vardai.** [Small botanical dictionary. I. Plant names.] *Želmenija* 2: 50-62, 67-72, 1922.—[See also Bot. Absts. 11, Entry 1049.]

896. SARASIN, FRITZ, und JEAN ROUX. **Nova Caledonia. Forschungen in Neu-Caledonien und auf den Loyalty-Inseln. Botanik.** [New Caledonia. Researches in New Caledonia and on the Loyalty Islands. Botany.] 4 to. Vol. I-L. iii. p. 177-311, pl. 7-8. C. W. Kreidel's Verlag: Berlin and Wiesbaden, 1921.—The present part of this extensive work is edited by HANS SCHINZ and A. GUILLAUMIN. Several specialists have cooperated in the study of different groups of plants. The taxonomic portion of the work consists of an enumeration of plants from the Gonystilaceae to the Compositae inclusive, and a short supplement. A limited bibliography and synonymy, a statement of general distribution, together with the habitat of the plant in New Caledonia or in the Loyalty Islands accompany each species recorded. Detailed descriptions of several species new to science are given, as well as critical notes on previously published species. A chapter entitled Cécidies de la Nouvelle-Calédonie by C. HOUDARD is included; and an extended chapter is added under the caption of Essai de Géographie Botanique de la Nouvelle-Calédonie by A. GUILLAUMIN. The new species and combinations included are: *Grewia crenata* Schinz & Guillaumin (*Mallocoeca crenata* Forster), *Hybanthus ilicifolius* Schinz & Guillaumin (*Ionidium ilicifolium* Vieill.), *Eugenia Sarasinii* Guillaumin, *Xanthostemon sulfureum* Guillaumin, *Rapanea Rouzii* Guillaumin, *Achradotypus Sarasinii* Guillaumin & Dubard, *Solanum camptostylum* Bitter, *S. neo-caledonicum* Bitter & Schlechter, *S. noumeanum* Bitter, *S. Vieillardii* Bitter, *Pseuderanthemum loyaltiense* Guillaumin, *Psychotria pulchrebracteata* Guillaumin, *Ficus mareensis* Warburg, and *Moorea streptophylla* Guillaumin.—J. M. Greenman.

897. SARGENT, C. S. [List of determinations of plants collected in Chekiang.] Ko-Hsueh [Science-Publ. Chinese Sci. Soc.] 7: 269-273. 1922.—The author presents a list of 98 plants, collected in Chekiang province, China.—Chunjen C. Chen.

898. TURRILL, W. B. [Rev. of: VALLENTIN, MRS. E. F. **Illustrations of the flowering plants and ferns of the Falkland Islands.** With descriptions by Mrs. E. M. Cotton. xii + 64 pl. + text + ii. L. Reeve and Co.: London. 1921 (see Bot. Absts. 11, Entry 3201).] *Nature* 109: 370. 1922.

SPERMATOPHYTES

899. ANONYMOUS. [Rev. of: GAMBLE, J. S. **Flora of the Presidency of Madras.** Pt. 4. **Rubiaceae to Ebenaceae.** p. 579-768. Adlard and Son and West Newman: London, 1921 (see Bot. Absts. 10, Entry 1413).] *Nature* 108: 464. 1921.

900. BATTANDIER, J. A. *Labiée ligneuse du Maroc constituant un nouveau type générique.* [Ligneous mint of Morocco constituting a new genus.] Bull. Sta. Recherches Forest. Nord. Afrique 1: 200-201. Pl. 21. 1921.—The type description of a new woody plant of the mint family is given. It is the only species of a new genus, *Pitardia*, and is named specifically *P. nepetoides* Batt.—J. Kittredge, Jr.

901. BLAKE, S. F. *A remarkable new species of Ichthyothere.* Jour. Washington [D. C.] Acad. Sci. 11: 301-303. Fig. 1. 1921.—This genus, which is represented by about a dozen species, all South American, is of economic importance among the natives because the bruised leaves and stems when placed in water tend to stupefy fish, making them easy to capture. All the previously known plants are distinguished by being low herbs or somewhat shrubby plants with compact inflorescence. A new species, collected by F. W. Pennell in Colombia, has loosely racemose-panicked heads and climbing habit. It is described under the name *I. scandens* Blake.—Helen M. Gilkey.

902. BLAKE, S. F. *Key to the genus Diplostephium, with descriptions of new species.* Contrib. U. S. Nation. Herb. 24: 65-86. Pl. 21-28. 1922.—The introduction to this paper contains a history of the chiefly South American genus *Diplostephium* of the family Asteraceae, with a discussion of the characters afforded by the modifications of the style branches in the genus and of their evolutionary significance. It is followed by a description of the genus and a key to the 5 groups and 40 species recognized. An additional doubtful species is also listed. The following new species and new names occur: *Diplostephium adenachaenium*, *D. empetrifolium*, *D. parvifolium* (*D. microphyllum* Wedd., not Nees), *D. pycnophyllum*, *D. macrocephalum*, *D. cicatricosum*, *D. oblanceolatum*, *D. baccharideum*, *D. revolutum*, *D. Weddellii* (*D. sessiliflorum* Wedd., not Spreng.), *D. sejaense* (Kuntze), *D. umbelliferum*, *D. pleistogynum*, *D. costaricense*, *D. obtusum*, *D. bicolor*, *Aplopappus canus* (A. Gray), *Gynoxys foliosa* (Rusby). Eight of the new species described are illustrated by photographs.—S. F. Blake.

903. BLAKE, S. F. *Two new species of Acanthospermum from the Galapagos Islands.* Jour. Washington [D. C.] Acad. Sci. 12: 200-205. Fig. 1. 1922.—*Acanthospermum brachyceratum* and *A. leptolobum* are described, and a key is included for these 2 species, together with *A. lecocarpoides*. These are all the known species belonging to the *Lecocarpopsis* section of the genus, and are all from the Galapagos Archipelago.—Helen M. Gilkey.

904. BUSCALIONI, LUIGI, e GIUSEPPE MUSCATELLO. *Studio monografico sulle specie americane del gen. "Saurauia" Willd.* [Monograph of American species of the genus *Saurauia* Willd. (continued).] Malpighia 29: 231-246. 1922.—Several varieties of *Saurauia leucocarpa* Schlecht. are compared and their affinities discussed.—Edith K. Cash.

905. CANDOLLE, CAS. DE. *Zwei neue Piper aus Neu-Mecklenburg.* [Two new Pipers from New Mecklenburg.] Bot. Jahrb. 57: 354-355. 1922.—This is No. 71 of Series VIII of the Beiträge zur Flora von Papuasien. *Piper Peekelii* and *P. anisopleurum*, both of the Bismark Archipelago, are described as new.—K. M. Wiegand.

906. COWAN, J. M., and A. M. COWAN. *The species of the genus Dipterocarpus found in the Chittagong District.* Indian Forester 48: 68-73. Pl. 5-6. 1922.—The 6 known species of *Dipterocarpus* are described and a key for their identification is given. That more species have not been found is probably due to the size of the trees and the fragmentary specimens which have been secured.—E. N. Munns.

907. DIELS, L. *Die Myrtaceen von Papuasien.* [The Myrtaceae of Papuasiasia.] Bot. Jahrb. 57: 356-426. Fig. 1. 1922.—This is No. 72 of Series VIII of the Beiträge zur Flora von Papuasien. The Myrtaceae of Papuasiasia comprise 20 genera and 160 species. With respect to this family the region may be divided geographically and as to affinities into (a) the primary forest and mountain bush, and (b) the savannahs and secondary bush. The former is further

divided into (1) the coast zone up to 1000 m. altitude, and (2) the upper zone above 1000 m. The Myrtaceae of the coast zone are related to those of Malasia and west and north Australia. In the upper zone there is a strong element related to plants in widely different parts of the world, even South America, suggesting that the mountains of Papuasias possess an important element of the ancient flora of the southern hemisphere. The savannah region shows a distinct relation to drier portions of Australia. The genera included are *Rhodamnia* Jack., *Myrtella* F. v. M., *Xanthomyrtus* Diels, *Psidium* L., *Decaspermum* Forst., *Octamyrtus* Diels, *Jossinia* Comm., *Eugenia* L., *Rhodomyrtus* DC., *Jambosa* DC. (50 species), *Syzygium* Gärtn. (44 species), *Xenodendron* L. & S., *Metrosideros* Banks, *Mearnsia* Merrill, *Xanthostemon* F. v. M., *Tristania* R. Br., *Eucalyptus* L'Her., *Leptospermum* Forst., *Melaleuca* L., and *Baeckea* L. The following new species, varieties, and combinations are proposed: *Rhodamnia Ledermannii*, *R. sepicana*, *R. polyantha*, *R. lamprophylla*, *Xanthomyrtus fasciculata*, *X. Schlechteri*, *X. longicuspis*, *X. longicuspis*, var. *fruticosa*, *X. scolopacina* (*Eugenia scolopacina* Ridley), *X. Pullei*, *X. polyclada*, *X. Klossii* (*Myrtus Klossii* Ridley), *X. arfakensis* (*Myrtus arfakensis* Gibbs), *X. linnaeifolia*, *X. koëbrensis* (*Myrtus koëbrensis* Gibbs), *X. calythrachoides*, *X. prostrata* (*Myrtus prostrata* Gibbs), *X. compacta* (*Myrtus compacta* Ridley), *Decaspermum leptanthelium*, *D. arfakense*, *D. laxiflorum* (*Nelitis laxiflora* Bl.), *D. prunoides*, *D. humifusum*, *D. petraeum*, *D. coriandri* (*Nelitis coriandri* Bl.), *D. rhodoleucum*, *Octamyrtus pleiopetala* (*Eugenia pleiopetala* F. v. Müll.), *O. insignis*, *O. Behrmannii*, *Jossinia Schlechteri*, *Rhodomyrtus novoguineensis*, *Jambosa longipes* Warb. var. *leptopoda*, *J. Bartonii* (*Eugenia Bartonii* Bailey), *J. gonatantha*, *J. papuana* (?*Decaspermum papuanum* Lauterb.), *J. Leonhardi*, *J. keroantha*, *J. platycarpa*, *J. alutacea*, *J. verniciflora*, *J. brevicyma*, *J. riparia*, *J. salicina*, *J. phacelantha*, *J. polyphlebia*, *J. gonioptera*, *J. cladoptera*, *J. combretiflora*, *J. xylopiacea*, *J. tympanantha*, *J. soliflora*, *J. tricolor*, *J. trachyantha*, *J. lagynocalyx*, *J. pycnantha*, *J. pachyantha*, *J. decoriflora*, *Syzygium triphlebium*, *S. orthoneurum*, *S. modestum*, *S. Pullei*, *S. subsimile*, *S. Schumanniana* (*Jambosa Schumanniana* Niedenzu), *S. cruriflorum*, *S. Schlechteri*, ?*S. recurvo-venosum* (?*Jambosa recurvo-venosa* Lauterb.), *S. heloanthum*, *S. dictyoneurum* and var. *oreogonum*, *S. Caroli*, *S. viburnoides* *S. Torricellianum*, *S. rosaceum*, *S. leptophlebium*, *S. platypodum*, *S. leptoneurum*, *S. oxyphyllum* *S. scytophyllum*, *S. tolypanthum*, *S. ganophyllum*, *S. leucoderme*, *S. effusum* (*Eugenia effusa* A. Gray), *S. homichlophilum*, *S. petraeum*, *S. leptanthelium*, *S. taeniatum*, *S. benjaminum*, *S. alatum* (*Aphanomyrtus alata* Lauterb.), *S. lamprophyllum*, *S. gyrostemoneum*, *S. brachyanthelium*, *S. pyrrophloeum*, *S. dolichorhynchum*, *S. Peekelii*, *S. iteophyllum*, *Metrosideros brachyanthera*, *M. iteophylla*, *M. Pullei*, *M. hypargyrea*, *M. aurea* (*Bacchousia aurea* Ridley), *M. Gibbsiae* (*Bacchousia arfakensis* Gibbs), *Mearnsia ramiflora* (*Metrosideros ramiflora* Lauterb.) and var. *humilis*, *Tristania oreophila*, and *Eucalyptus Schlechteri*. The genera *Xanthomyrtus* and *Octamyrtus* are described as new.—K. M. Wiegand.

908. DIELS, L. Beiträge zur Kenntnis der Combretaceen von Papuasien. [Contributions to the knowledge of the Combretaceae of Papuasias.] Bot. Jahrb. 57: 427-430. 1922.—This is No. 73 of Series VIII of the Beiträge zur Flora von Papuasien. Notes are given on the 2 species of *Combretum* L. and the 8 species of *Terminalia* L. known from Papuasias. *Terminalia oreadum*, *T. phaeoneura*, and *T. sepicana* are described as new. *Combretum flavo-virens* Lauterb. is *Pygeum dolichobotrys* Lautb. & Schum., *Terminalia trinervia* Lautb. & Schum. belongs to the Flacourtiaceae and should be called *Bennettia trinervia* (Lautb. & Schum.) Gilg. n. comb.—K. M. Wiegand.

909. DIELS, L. Die aus Papuasien bekannten Theaceen. [The Theaceae known from Papuasias.] Bot. Jahrb. 57: 431-435. 1922.—This is No. 74 of Series VIII of the Beiträge zur Flora von Papuasien. The Theaceae do not form an important part of the flora of Papuasias. Those found are all above 500 m. altitude, mostly between 1000 and 2000 m. Four genera and 8 species are listed. The genera are *Gordonia* Ell., *Ternstroemia* L., *Adinandra* Jack., and *Eurya* Thunb. The following species and varieties are described as new: *Adinandra calosericea*, *Eurya leptantha*, *E. tigang* K. Schum. vars. *meizophylla* and *phyllopoda*, and *E. oxysepala*.—K. M. Wiegand.

910. DIELS, L. *Die Dilleniaceen von Papuasien.* [The Dilleniaceae of Papuasiasia.] Bot. Jahrb. 57: 436-459. 1922.—This is No. 75 of Series VIII of the Beiträge zur Flora von Papuasien. In this paper 3 genera and 56 species are treated. The genera included are *Dillenia* L., *Tetracera* L., and *Saurauia* Willd. (41 species). The following new species, varieties, combinations, and names are proposed: *Dillenia macrophylla* (D. *alata* var. *macrophylla* Lauterb.), *D. calothyrsa*, *D. montana*, *D. Schlechteri*, *D. castaneifolia* Miq. var. *dolichobotrys*, *Tetracera lanuginosa*, *T. floribunda*, *T. pilophylla*, *Saurauia meiantra*, *S. drimytiliflora*, *S. desquamulata*, *S. iboana*, *S. Schumanniana* (S. *rosea* Lauterb., not Jungh.), *S. pilogyne*, *S. submodesta* and var. *procumbens*, *S. holotricha*, *S. Caroli*, *S. xiphophylla*, *S. amplifolia*, *S. echiioides*, *S. stirrolepida*, *S. vagans*, *S. phaeosepala*, *S. rupestris*, *S. buddleifolia*, *S. egregia*, *S. pannosa*, *S. achyrantha*, *S. Naumannii*, *S. oreadam* and var. *humilis*, and *S. Rudolphi*.—K. M. Wiegand.

911. DIELS, L. *Die Dipterocarpaceen von Papuasien.* [The Dipterocarpaceae of Papuasiasia.] Bot. Jahrb. 57: 460-463. 1922.—This is No. 76 of Series VIII of the Beiträge zur Flora von Papuasien. The few species known from this region are found at lower altitudes and are related to those of Celebes and the Philippines. This is probably a young element in the flora. Four genera and 10 species are listed. Of these species *Hopea papuana* is described as new, and 2 other new species are noted but without names. The genera included are *Anisoptera* Korth., *Hopea* Roxb., *Shorea* Roxb., and *Vatica* L.—K. M. Wiegand.

912. DIELS, L. *Die Bignoniaceen von Papuasien.* [The Bignoniaceae of Papuasiasia.] Bot. Jahrb. 57: 496-500. Fig. 1. 1922.—This is No. 78 of Series VIII of the Beiträge zur Flora von Papuasien. With the exception of 2 more widely distributed species the Bignoniaceae of Papuasiasia are endemic. They are found both on the lowlands and highlands. The genera represented are *Tecomnanthe* Baill., *Pandorea* Spach., *Neosepicaea* Diels, and *Dolichandrone* Fenzl. The genus *Neosepicaea* is described as new. The following new species and combinations are proposed: *Tecomnanthe aurantiaca*, *T. montana*, *T. saxosa*, *Pandora stenantha*, ?*P. leptophylla* (*Tecoma leptophylla* Bl.), *Neosepicaea viticoides*.—K. M. Wiegand.

913. ENGLER, A. *Ein neuer Saxifragen-Bastard.* [A new hybrid in Saxifraga.] Bot. Jahrb. 57: Beibl. 127: 63. 1922.—The hybrid described is *Saxifraga cuneifolia* × *rotundifolia*, also named × *S. Mattfeldii* n. sp. It was collected by Mattfeld in Kärnthen near Hermagor.—K. M. Wiegand.

914. ENGLER, A. *Saxifragaceae-Saxifraga (Pars generalis).* Pflanzenreich Heft 69 (IV. 117). p. 1-47, 4 fig. 1919.—The author presents a general introductory part to the monograph of *Saxifraga* in which he gives the most important literature pertaining to the genus, a detailed statement of the morphology, the geographical distribution, and the relationships within the family. In connection with the geographical distribution of the genus 3 great floral kingdoms are designated, namely, (1) Boreales Florenreich, (2) Palaetotropisches Florenreich, and (3) Zentral- und südamerikanisches Florenreich. These floral kingdoms are divided variously into territories, and the territories again into provinces. The species of *Saxifraga* most characteristic of the individual provinces are enumerated.—J. M. Greenman.

915. ENGLER, A., UND E. IRMSCHER. *Saxifragaceae-Saxifraga. II. Sectiones Trachyphyllum, Xanthizoon, Euaizoonia, Kabschia, Porphyryon, Tetrameridium, Diptera Spec.* 234-302 et Additamentum. Pflanzenreich Heft 69 (IV. 117. ii). p. 449-709, 24 fig. 1919.—The present, or 2nd, part of this monograph is concerned with an elaboration of the sections mentioned in the title and includes about 70 species, numerous varieties, forms, and hybrids. Several species, for example, *Saxifraga aspera* L., *S. aizoides* L., *S. bronchialis* L., *S. lingulata* Bell., *S. aizoon* Jacq., *S. porophylla* Bertol., and *S. oppositifolia* L. are designated as polymorphic types. These types, or species, are divided variously into subordinate categories, namely, subspecies, varieties, forms, hybrids, etc., which are described and exemplified by the citation of exsiccata, and their geographical distribution is given in considerable detail. A number of new varieties, combinations, and hybrids are recorded. The supplement contains

many additions and corrections for annotation in the 1st part of the monograph, which was issued in 1916. The new species, described here for the first time, are: *Saxifraga Stolitzkae* Duthie, *S. subsessiliflora* Engl. & Irmsch., *S. kumaunensis* Engl., and *S. quadrifaria* Engl. & Irmsch., all indigenous to the Himalayan region.—J. M. Greenman.

916. HARMS, H. Eine neue Art von *Platymiscium* (Leguminosae) aus Brasilien. [A new species of *Platymiscium* from Brazil.] Bot. Jahrb. 57: Beibl. 127: 64. 1922.—The species described is *Platymiscium Zehntneri*.—K. M. Wiegand.

917. HITCHCOCK, A. S. A perennial species of teosinte. Jour. Washington [D. C.] Acad. Sci. 12: 205–208. 1922.—This first perennial species of teosinte, which was collected by the author in Mexico in 1910, differs from all other known species by the possession of rhizomes, and is described under the name *Euchlaena perennis*.—Helen M. Gilkey.

918. HUTCHINSON, J. *Rhododendron praeteritum* n. sp. Gard. Chron. 71: 149. Fig. 73. 1922.—The plant described was grown at Kew Garden and is related to *R. maculiferum* and *R. oreodoxa* Franch.—P. L. Ricker.

919. KILLIP, E. P. New *Passifloras* from Mexico and Central America. Jour. Washington [D. C.] Acad. Sci. 12: 255–262. 1922.—Eleven new species are described under the following names: *Passiflora apetala*, *P. fruticosa*, *P. Cookii*, *P. costaricensis*, *P. Heydei*, *P. panamensis*, *P. Rovirosae*, *P. talamancensis*, *P. platyloba*, *P. Purpursii*, *P. Williamsii*. The variety known as *P. foetida arida* Mast. & Rose, has been raised to specific rank under the name *P. arida*.—Helen M. Gilkey.

920. KRAUSE, K. Die *Loranthaceen* Papuasiens. [The *Loranthaceae* of Papuaia.] Bot. Jahrb. 57: 464–495. Fig. 1–4. 1922.—This is No. 77 of Series VIII of the Beiträge zur Flora von Papuaia. The previously known species of *Loranthaceae* from this region have been increased from 24 to 57, distributed among 5 genera namely, *Elytranthe* Blume, *Loranthus* L., *Phrygilanthus* Eichl., *Notothixos* Oliv., and *Viscum* L. The majority of species are endemic. Plants of this family inhabit the various altitudinal zones, though certain genera or sections are characteristically lowland or alpine. Certain species are notable because of their creeping or twining habit about the host, a feature found also among certain Indian, Malayan, and American species. The following species and combinations are proposed as new: *Elytranthe macropoda*, *E. Versteegii* (*Loranthus Versteegii* Lauterb.), *E. pallidiflora*, *E. leucantha*, *E. Peekelii*, *E. Schlechteri*, *E. longifolia*, *E. neurophylla*, *E. acutifolia*, *E. Ledermannii*, *E. torulosa*, *E. verrucosa*, *E. spathulifolia*, *E. diversifolia*, *Loranthus kaniensis*, *L. djamuensis*, *L. Schultzei*, *L. basiflorus*, *L. obtusus*, *L. rigidiflorus*, *L. Thespesiae*, *L. tenuisepalus*, *L. Wichmannii*, *L. iboensis*, *L. articulatus*, *L. squarrosus*, *L. verticillifolius*, *L. melastomatifolius*, *L. molliflorus*, *L. spathatus*, *L. curvifolius*, *L. heterochromus*, *Phrygilanthus novo-guineensis*, *Notothixos spicatus*, *N. Schlechteri*, and *N. Ledermannii*.—K. M. Wiegand.

921. LAUTERBACH, C. Die *Lecythidaceen* Papuasiens. [The *Lecythidaceae* of Papuaia.] Bot. Jahrb. 57: 341–353. Fig. 1–4. 1922.—This is No. 70 of Series VIII of the Beiträge zur Flora von Papuaia. Of this family 3 genera and 21 species are found in this region of which 15 species are endemic. Some are showy trees of the coastal forests. *Barringtonia speciosa* L., *B. Schuchardtiana* K. Schum., and *B. Novae-Hiberniae* Laut. produce edible seed. With 2 exceptions the *Lecythidaceae* inhabit the lowlands. Twenty-five per cent of the endemic species are found only on New Pommern and New Mecklenburg. Keys to the genera and species are given. The genera treated are: *Planchonia* Bl., *Careya* Roxb., and *Barringtonia* Forst. The following species are described as new: *Barringtonia papeh* and *B. quadrigibbosa*, Bismark Archipelago; *B. pauciflora*, *B. apiculata*, and *B. sepikensis*, northeastern New Guinea. A new variety, *B. calyptrocalyx* K. Schum. var. *mollis*, is proposed.—K. M. Wiegand.

922. LAUTERBACH, C. Die *Rhamnaceen* Papuasiens. [The *Rhamnaceae* of Papuaia.] Bot. Jahrb. 57: 326–340. Fig. 1–3. 1922.—This is No. 69 of Series VIII of the Beiträge zur

Flora von Papuasien. Eight genera and 13 species are known from this region. Many species are found in the coastal swamps and along the river banks. A large number of lianes occur. The genera included are: *Ventilago* Gaertn., *Smythea* Seem., *Zizyphus* Juss., *Dallachya* F. v. M., *Rhamnus* L., *Colubrina* L. C. Rich., *Alphitonia* Reiss, and *Gouania* Jacq. Keys are given to the genera and species treated, and the following new species are proposed: *Smythea macrophylla*, *Zizyphus papuanus*, *Z. djamuensis*, *Rhamnus nigrescens*, *R. papuanus*, and *R. Schlechteri*, northeast New Guinea; *R. sumbawanus*, Sumbawa. New varieties are: *Gouania microcarpa* DC. vars. *papua*, *novo-hibernica*, *rugulosa*, and *mollis*. A key to the species and varieties of *Gouania* found in the monsoon region is given, and also a discussion of this genus.—K. M. Wiegand.

923. MAIDEN, J. H. A critical revision of the genus *Eucalyptus*. Vol. VI, Part 2. p. 61-106, pl. 212-215. William Applegate Gullick: Sydney, April, 1922.—This part introduces a chapter on Hybridization in the Genus; it is followed by descriptions and illustrations of the following hybrids: \times *Eucalyptus algeriensis* Trabut, *E. amplifolia* Naudin, \times *E. antipolitensis* Trabut, \times *E. Bourlieri* Trabut, \times *E. Cordieri* Trabut, \times *E. gomphocornuta* Trabut, \times *E. jugalis* Naudin, *E. occidentalis* Endl. var. *oranensis* Trabut n. var., \times *E. pseudo-globulus* (Hort.) Naudin, \times *E. Trabuti* Vilmorin, *E. Stuartiana* \times *globulus* Trabut, and \times *E. insizwaensis* Maiden n. sp. The chapter on Bark which was begun in the previous volume of this work is continued in the present part. *IBID.* Part 3. p. 107-164, pl. 216-219. May, 1922.—This part is concerned primarily with natural hybrids of which the following (except *Blackburniana*) are described and illustrated, as new: \times *Eucalyptus barmedmanensis*, \times *E. tenandrensis*, \times *E. Peacockeana*, \times *E. Stopfordi*, \times *E. Forsythii*, \times *E. auburnensis*, \times *E. yagobiei*, \times *E. Blackburniana*, and *E. studleyensis*. Miscellaneous notes on hybrids are added, and under the caption of Timber a discussion is given of the various *Eucalyptus* woods.—J. M. Greenman.

924. MAIRE, RENÉ. Les *Adenocarpus* de l'Afrique du Nord. [The members of the genus *Adenocarpus* of North Africa.] Bull. Sta. Recherches Forest. Nord Afrique 1: 211-217. Pl. 22-23. 1921.—North Africa is especially rich in *Adenocarpus*, containing 11 of the 18 known species. Of these, 7 are found in Morocco and 4 in Algeria. A list of these 11 species, with the localities of their occurrence, is given. Technical notes are recorded in Latin for a little known species, *A. umbellatus* Coss. & Dur. Two new species are described, *A. Faurei* and *A. Boudyi* Batt. & Maire. A key to the North African species is also included.—J. Kittredge, Jr.

925. MATTFELD, JOH. Beitrag zur Kenntnis der systematischen Gliederung und geographischen Verbreitung der Gattung *Minuartia*. [Contribution to the knowledge of the systematic subdivision and geographical distribution of the genus *Minuartia*.] Bot. Jahrb. 57: Beibl. 127: 13-63. 1922.—The genus as here understood includes *Arenaria*, *Cherleria* L., *Queria* L., *Honckenya* Ehrh., *Rhodalsine* Gay, *Greniera* Gay, *Siebera* Schrad., and *Hymenella* Moc. & Sess. The paper consists of 2 chapters, of which the 1st deals with the relationship of genera in the *Alsinoideae* and the 2nd with the subdivision of the genus into sections and groups, with consideration of their geographical distribution. In the former it is noted that the genera with a 5-carpetted gynoeceum are relatively primitive. The reduction to 4 carpels occurs readily in diverse groups, while the 3-carpetted gynoeceum is more distinct and more fundamental. The author notes Fernald's discussion of the unity of the genus *Arenaria*. The 2nd chapter is subdivided as follows: (1) Limits of the genus. (2) Historical account of the attempts at classification. (3) Account of the essential characteristics: a. germination and cotyledons; b. growth forms and inflorescence of annuals; c. growth forms and inflorescence of perennials; d. anatomy of the stem and the trichomes; e. foliage; f. calyx and sepals; g. corolla; h. androeceum and staminal glands; i. gynoeceum; j. seeds; k. diclinism. (4) Division of the genus into sections and groups. Seventeen sections are proposed and discussed, and a key to these is given. The center of distribution of the genus is Europe with many species in North America, while the genus is almost unrepresented in eastern Asia, Africa, and South America. *Minuartia Engleri* and *M. Wettsteinii*, both of southern Europe, are described as new.—K. M. Wiegand.

926. PAX, F., UND KÄTHE HOFFMANN. *Euphorbiaceae-Acalyphaeae-Plukenetinae. Euphorbiaceae-Acalyphaeae-Epiprininae. Euphorbiaceae-Acalyphaeae-Ricininae.* Pflanzenreich Heft 68 (IV. 147, ix-xi). 184 p., 29 fig. 1919.—This paper concerns 19 genera, of which *Tragia* with 126 species is by far the largest. A few new genera are proposed; certain sections of Müller are raised to generic rank, several new species are described, and new combinations made. These are: *Eleutherostigma* n. gen. with 1 species, *E. Lehmannianum*, from Colombia; *Angostylidium* (*Plukenetia* Sect. *Angostylidium* Müll. Arg.) n. gen., *A. conophorum* (*Plukenetia conophora* Müll. Arg.); *Apodandra* n. gen. from Peru and Bolivia, *A. lorentensis* (*Plukenetia lorentensis* Ule), *A. Buchtienii* (*Plukenetia Buchtienii* Pax); *Pterococcus corniculatus* (*Plukenetia corniculata* Sm.), *P. africanus* (*Plukenetia africana* Sond.), *P. procumbens* (*Plukenetia procumbens* Prain); *Anabaenella* (*Anabaena* Juss., not Rehb.) n. gen., *A. tamnoides* (*A. tamnoides* Juss.), *A. tamnoides* vars. *genuina* and *sinuata* (*Plukenetia sinuata* Ule); *Haematostemon* (*Astrococcus* Sect. *Haematostemon* Müll. Arg.) n. gen., *H. coriaceus* (*Astrococcus coriaceus* Baill.); *Tragia leucandra* (*Leucandra betonicifolia* Klotzsch), *T. fallacina*, *T. caperonioides*, *T. catamarcensis*, *T. Emilii*, *T. volubilis* L. vars. *longifolia* and *pedicellaris* (*T. pedicellaris* Müll. Arg.), *T. amblyodonta* (*T. nepetifolia* var. *amblyodonta* Müll. Arg.), *T. tenella*, *T. aliena*, *T. paraguariensis* and vars. *canescens*, *macrophylla* (*T. uberabana* var. *macrophylla* Chod. & Hass.), *subsessilis* (*T. bahiensis* var. *subsessilis* Chod. & Hass.), *discolor* (*T. uberabana* var. *discolor* Chod. & Hass.), and *glabrescens*, *T. microcarpa*, *T. pseudomelochioides*, *T. adenophila* and vars. *mollis*, *ferruginea*, and *glanduligera*, *T. depauperata*, *T. urens* L. var. *innocua* (*T. innocua* Walt.), *T. Hieronymi*, *T. Karsteniana*, *T. Stolziana*, *T. pungens* (Forsk.) Müll. Arg. vars. *genuiana* Pax & Hoffm. and *cinerea* Pax, *T. Mülleriana* vars. *cordata* and *unicolor* (Müll. Arg.), *T. cannabina* L. f. vars. *hastata* (L.) and *Hildebrandtii* (Müll. Arg.), *T. lasiophylla*, *T. dioica* Sond. vars. *lobata* (Müll. Arg.) and *Schinzi* Pax, *T. lancifolia* Dinter, *T. glabrata* (*T. Meyeriana* var. *glabrata* Müll. Arg.), *T. furialis* Bojer vars. *eufurialis* (*T. furialis* Prain) and *Scheffleri* (*T. Scheffleri* Bak.). *T. Milbraediana*; *Tragiella* n. gen. of African plants, *T. natalensis* (*Tragia natalensis* Sond.), *T. anomala* (*Tragia anomala* Prain), *T. Friesiana* (*Tragia Friesiana* Prain); *Sphaerostylis malaccensis* (*Megistostigma malaccense* Hook. f.), and *Pachystylidium* n. gen. from Java and the Philippines, represented by *P. hirsutum* (*Tragia hirsuta* Blume) vars. *genuina* and *irritans* (*Tragia irritans* Merrill); *Epiprinus malayanus* Griff. vars. *genuinus* and *Balansae*; *Ricinus communis* L. var. *inermis* (*R. inermis* Jacq.).—J. M. Greenman.

927. PAX, F., UND KÄTHE HOFFMANN. *Euphorbiaceae-Additamentum VI.* Pflanzenreich Heft. 68 (IV. 147, xiv). 81 p. 1919.—In the present supplement the authors give a brief discussion of the relationship and natural sequence of the first 10 tribes of the Euphorbiaceae, followed by a dichotomous key to the tribes, subtribes, and the 198 recognized genera. Numerous additions are recorded for insertion in previously published parts of the monograph of this family. Several plants new to science are described, mostly from Australasia and Brazil; a list of collectors and specimens cited is also given. The new genera, species, varieties, and combinations included are as follows: *Caperonia similis*, *Annesijoa* n. gen. from New Guinea, *A. novoguineensis*, *Mareya spicata* Baill. var. *micrantha* (*Acalypha micrantha* Benth.), *Mareyopsis longifolia* (*Mareya longifolia* Pax), *Clarorivinia grandifolia*, *Blumeodendron borneense*, *B. papuanum*, *Claoxylon lutescens*, *C. glabrifolium* Miq. var. *integrifolium*, *C. Warburgianum*, *C. carolinianum*, *Mallotus batjanensis*, *M. sanguirensis*, *M. Warburgianus*, *M. papuanus* (J. C. Smith) Pax & Hoffm. vars. *genuinus*, *intermedius*, and *glabrescens*, *Alchornea brachygynae*, *Cleidion Minahassae*, *C. membranaceum*, *Macaranga parvibracteata*, *M. pleiostemona*, *M. haplostachya*, *M. polyadenia*, *M. lanceolata*, *M. effusa*, *M. penninervia*, *M. crassistipulosa*, *M. mallotiformis*, *M. villosula*, *M. acuminata*, *M. brunneofloccosa*, *M. carolinensis* Volkens var. *grandifolia*, *M. ovalifolia*, *M. pseudopeltata*, *M. similis*, *M. caudata*, *M. platyclada*, *M. strigosa*, *M. fallacina*, *M. advena*, *M. gracilis*, *Jatropha brevifolia* (*J. gossypifolia* var. *brevifolia* Morong), *Clutia heterophylla* Thunb. var. *disceptata* (*C. disceptata* Prain), *Pausandra quadriglandulosa*, *Cunuria Uleana*, *Neoscortechinia arborea* (*Alcinaeanthus arboreus* Pax & Hoffm.) and var. *parvifolia* (*A. parvifolius* Merrill), *N. Kingii* (*Scortechinia Kingii* Hook. f.), *N. nicobarica* (*S. nicobarica* Hook. f.), *Neomphalea papuana* (*Omphalea papuana*

Pax & Hoffm), *Senefeldera triandra*, *Mabea anadena*, *M. atroviridis*, *M. depauperata*, *M. sub-sessilis* (*M. anomala* Glaziov), *M. Uleana*, *Homalanthus polyadenius*, *Actinostemon depauperatus*, *A. Glaziovii* (*A. grandifolius* Glaziov), and *Sapium Türckheimianum*.—J. M. Greenman.

928. PAX, F., UND KÄTHE HOFFMANN. **Euphorbiaceae-Dalechampieae**. Pflanzenreich Heft 68 (IV. 147, xii). 59 p., 9 fig. 1919.—The genus *Dalechampia* is held by the authors to represent a distinct tribe of the Euphorbiaceae, allied to other members of this family through *Plukenetia* and *Tragia*. The group embraces 88 species, distributed mainly in the American tropics. The following new species, varieties, names, and combinations are included: *Dalechampia panamensis*, *D. madagascariensis* (*D. ternata* var. *madagascariensis* Müll. Arg.), *D. Weberbaueri*, *D. pallida* Klotzsch, *D. micromeria* Baill. vars. *genuina* and *angustifolia*, *D. Bangii*, *D. anomala*, *D. heteromorpha*, *D. stipulacea* Müll. Arg. var. *bogotensis*, *D. Martiana* Klotzsch, *D. Karsteniana*, *D. Uleana*, *D. bidentata* Blume vars. *genuina* and *yunnanensis*, *D. scandens* L. vars. *pernambucensis* (*D. pernambucensis* Baill.), *pseudoclematidis* (*D. pseudoclematidis* Baill.), *Hildebrandtii* Pax (*D. Hildebrandtii* Pax), and *natalensis* (*D. natalensis* Müll. Arg.), *D. Hersogiana*, *D. linearis* Baill. var. *goyazensis* (*D. goyazensis* Müll. Arg.), *D. morifolia*, *D. amambayensis*, *D. rubrivenia*, *D. trichophila*, *D. serrula*, *D. Schenckiana*, *D. boliviano*, *D. tenuiramea* Müll. Arg. vars. *genuina* and *cynanchoides* (*D. cynanchoides* Moore), *D. ulmifolia* Chod. & Hassl. vars. *genuina* and *Grüningiana* Pax (*D. Grüningiana* Pax), and *D. parvula*.—J. M. Greenman.

929. PAX, F., UND KÄTHE HOFFMANN. **Euphorbiaceae-Pereae**. Pflanzenreich Heft 68 (IV. 147, xiii). 14 p., 2 fig. 1919.—The authors interpret *Pera* as representing a distinct tribe of the Euphorbiaceae, and recognize about 20 species all of which are trees or shrubs occurring in the American tropics. One new species is described and 1 new combination made, namely, *Pera Glaziovii* Taubert and *P. barbinervis* (*Spixia barbinervis* Mart.).—J. M. Greenman.

930. PITTIER, H. **On the species of Dalbergia of Mexico and Central America**. Jour. Washington [D. C.] Acad. Sci. 12: 54-64. 1922.—Eight new species, as follows, are described: *Dalbergia melanocardium*, *D. congestiflora*, *D. tabascana*, *D. cibiz*, *D. mexicana*, *D. hypoleuca*, *D. granadillo*, and *D. lineata*. *D. cubilquitzensis* (Donn. Smith) Pittier is added, and a key for all the known species of the region is published. In addition to the new species, the following are included in the key: *D. tucurensis* Donn. Smith, *D. glomerata* Hemsl., *D. campecheana* Benth., *D. Brownei* (Jacq.) Urban, *D. ecastophyllum* (L.) Taub., *D. monetaria* L., *D. calycina* Benth., *D. retusa* Hemsl.—Helen M. Gilkey.

931. ROSENTHAL, KÄTHE. **Daphniphyllaceae**. Pflanzenreich Heft 68 (IV. 147a). 16 p., 1 fig. 1919.—The author reinstates the family Daphniphyllaceae, as distinct from the Euphorbiaceae, and refers to it the single genus *Daphniphyllum* which comprises 24 known species, endemic in southeastern Asia. The following new species, combinations, and varieties are included: *Daphniphyllum celebense*, *D. nilgherrense* (*Gouphia nilgherrensis* Wight) and var. *concolor* (*D. glaucescens* var. *concolor* Müll. Arg.), *D. Oldhamii* (*D. glaucescens* var. *Oldhami* Hemsl.), *D. macropodium* Miq. var. *humile* (*D. humile* Maxim.), *D. bengalense*, *D. chartaceum*, *D. latifolium*, *D. Paxianum*, *D. longeracemosum*, and *D. gracile*.—J. M. Greenman.

932. TRELEASE, WILLIAM. **The peltate peperomias of North America**. Bot. Gaz. 73: 133-147. Pl. 1-4. 1922.—An historical account of the taxonomy of the peltate peperomias is given together with a synopsis of the group. The latter presents the species in 8 subgenera which are arranged in 4 groups. The following new species appear: *Peperomia Painteri*, *P. astyla*, *P. Parryana*, *P. tenuimucronata*, *P. schizandra*, *P. amphoricarpa*, *P. schizostachya*, *P. Killipi*, *P. cordulatiformis*, *P. peltitimba*.—B. W. Wells.

BOTANICAL ABSTRACTS

A monthly serial furnishing abstracts and citations of publications in the international field of botany in its broadest sense.

C. V. PIPER, *Editor*

MARY R. BURR, *Assistant Editor*

(See also in this issue Entries 1033, 1046, 1048, 1052, 1058, 1062, 1064, 1116, 1229, 1292, 1302, 1368, 1419, 1420, 1423, 1427, 1447, 1461, 1473, 1476, 1478, 1479, 1489, 1490, 1493, 1495, 1497, 1512)

933. ANONYMOUS. Candle-nut oil. Agric. Bull. Federated Malay States 9: 176. 1922.—A description is given of the process of extracting oil from the candle-nut.—I. H. Burkill.

934. ANONYMOUS. Napier fodder. Rhodesian Agric. Jour. 19: 194-199. 1922.—Extracts are given of reports from various sources of elephant grass (*Pennisetum purpureum* Schumacher (*P. Bentharii* Steudel)), the Napier fodder of Rhodesia. Napier fodder, which attains a height of 15-18 feet, shows an aptitude for growing on poor soil and though not as palatable as many other well known grasses, cattle do well on it. Records show that cows fed on Napier fodder and allowed to graze occasionally on natural pastures maintain milk yields and butter fat tests. Pulp from which good quality paper is manufactured has been obtained in Uganda from Napier fodder although at present export of the raw material would be unprofitable.—L. J. Goldblatt.

935. ANONYMOUS. Pasture plants and grasses in Rhodesia. Results of further trials. Rhodesia Agric. Jour. 19: 439-443. 1922.—Reports, compiled by the Chief Agriculturist, are given from farmers who tested the following: Rhodesian tussock grass, Penhavanga grass, Kikuyu, Kudzu vine, swamp couch grass, Buffel grass, *Paspalum dilatatum*, Napier fodder, *Phalaris bulbosa*, native Paspalum, and Florida beggar weed.—L. J. Goldblatt.

936. ANONYMOUS. Varieties of maize. Recommendations by the Department of Agriculture. Agric. Gaz. New South Wales 33: 549-551. 1922.—Twelve maize districts are given for New South Wales. Maize varieties are grouped geographically relative to earliness of the variety, use of the crop, and character of the soil.—L. R. Waldron.

937. ANONYMOUS. Varieties of potatoes. Recommendations by the Department of Agriculture. Agric. Gaz. New South Wales 33: 552. 1922.—Varieties for New South Wales are classified geographically and according to earliness.—L. R. Waldron.

938. ARNOLD, H. C. Propagation of Kudzu vine (*Pueraria Thunbergiana*). Rhodesia Agric. Jour. 19: 435-438. 1922.—Kudzu vines may be propagated either from seed or by rooted layers from the parent stock. In the latter case much less labor is entailed if unrooted slips are detached from the parent stock and planted in the permanent site. When the plant has become established, runners are sent out in all directions; in order to prevent patchiness these should be buried 1-2 inches as they grow, and within a foot of the growing tips.—L. J. Goldblatt.

939. BOSMAN, G. J. Potato culture. Jour. Dept. Agric. Union South Africa 5: 41-49. 1922.—An outline is given of the origin, history, and importance of the potato. The following points in potato culture are dealt with: climatic adaptations; soil requirements and preparation; planting; cultivation; manurial requirements; rotation; the seed; and the improvement of the stock.—L. Goldblatt.

940. BREAKWELL, E. Some useful introduced fodder plants. Agric. Gaz. New South Wales 33: 485-490. 2 fig. 1922.—Notes and descriptions are given for tagasaste (*Cytisus proliferus*), sainfoin (*Onobrychis sativa*), sulla (*Hedysarum coronarium*), teosinte (*Euchlaena luxurians*), Japanese clover (*Lespedeza striata*), Kudzu (*Pueraria Thunbergiana*), and sheep's burnet (*Poterium sanguisorba*). These plants are not commonly grown in New South Wales.—L. R. Waldron.

941. BREAKWELL, E. Some useful saltbushes. Agric. Gaz. New South Wales 33: 571-577. 7 fig. 1922.—Saltbushes of Australia belong mainly to the following 5 genera,—*Chenopodium*, *Atriplex*, *Kochia*, *Rhagodia*, and *Euchlaena*. Because of free-seeding and rapid-growing habits, ranging tracts carrying saltbushes are quickly brought to use after periods of drought. *Chenopodium atriplicinum* attains a height of 3-4 feet. *Atriplex nummularia* produces fodder in comparative abundance. Transplanted seedlings grew to a height of 10 feet at Nyngan during the summer of 1921-22 and 56 pounds of green feed per plant were obtained. Plants should be planted 12 feet apart. *A. leptocarpa* is not very palatable. *A. semibaccata* has been introduced successfully into California. Analyses are given of *A. nummularia*, *A. halimoides*, *A. angulata*, *Rhagodia parabolica*, and *R. hastata*.—L. R. Waldron.

942. BRUTSCHKE, FRITZ. Zur Förderung der landwirtschaftlichen Erzeugung. [Increasing agricultural production.] Mitteil. Deutsch. Landw. Ges. 37: 521-522. 1922.—A general plea is made for greater production and for economy in the use of seed.—A. J. Pieters.

943. BURTT DAVY, JOSEPH. Fermentation products from maize. South African Jour. Indust. 5: 245-254. 1922.—This article describes the use of maize starch in the production of fermented liquids, such as, beer, whisky, gin, brandy, vinegar, and especially industrial alcohol. Details of the manufacture and the various uses of the latter are very fully given.—Sydney M. Stent.

944. BURTT DAVY, JOSEPH. Starch and glucose from maize. 2 and 3. South African Jour. Indust. 5: 177-183, 217-222. 1922.—The process is described whereby starch is extracted from the grains of maize (*Zea Mays* L.) and converted into glucose. Various useful commodities are cited into the composition of which glucose largely enters.—Sydney M. Stent.

945. BURTT DAVY, JOSEPH. The uses of maize husks, cobs and chaff. South African Jour. Indust. 5: 407-413. Pl. 3. 1922.—The author describes the employment of maize husks in the manufacture of hats, mats, and other articles of domestic use; also the manufacture of gas for illuminating and heating purposes, pipes, charcoal, and stock-food from the cobs.—Sydney M. Stent.

946. BURTT DAVY, JOSEPH. Utilization of maize flowers, stalks and leaves 2. South African Jour. Indust. 5: 357-364. 1922.—This installment contains further information

regarding the utilization of maize stalks as a source of sugar, and refers to the published results of experiments by Stewart and Kerr, Blackshaw, and others on the possibility of increasing the sugar-content of the stalk. The use of maize straw in the manufacture of paper is also dealt with in detail.—*Sydney M. Stent.*

947. CLIFFORD, WALTER. Straw pulp as a substitute for groundwood for newsprint. *Paper Indust.* 3: 1105-1106. 1921.—The author urges the utilization of straw in place of wood and gives a description of a sulphate process for cooking straw.—*H. N. Lee.*

948. DAWSON, C. A. Crop production on small holdings 5. Lucerne. *South African Fruit Grower* 9: 127-129. *Fig. 1-4.* 1922.—Lucerne is considered the most suitable crop for extensive field culture under irrigation wherever soil and climatic conditions are suitable to its production.—*L. Goldblatt.*

949. DAWSON, C. A. Crop production on small holdings 6. Beans. *South African Fruit Grower* 9: 173. 1922.—Beans are usually grown as a green vegetable rather than for the dry seed, though the 2 could profitably be combined. For export, white beans are preferable to colored varieties. To prevent weevil infestation, dry beans should either be fumigated with carbon bisulphide or mixed with $\frac{1}{3}$ as much air-slaked lime, agricultural lime, or fine dry dust, followed by washing and sifting.—*L. Goldblatt.*

950. DOUGLASS, J. Field experiments with maize. Wollongbar experiment farm. *Agric. Gaz. New South Wales* 33: 464. 1922.—Maize from graded seed, planted as a fodder crop, outyielded similar ungraded seed by nearly 5 tons of green fodder, about 50 per cent per acre.—*L. R. Waldron.*

951. DOWNING, R. G., and L. G. LITTLE. Field experiments with oats. Nine years' results, 1912 to 1920. Glen Innes experiment farm. *Agric. Gaz. New South Wales* 33: 465-468. 1922.—Notes and yields are given for 12 varieties. Algerian is considered the best general variety. Fulghum variety shows promise; Kherson is not satisfactory; and a hull-less variety has proved to be of little value. Late varieties, represented by White Tartarian, have only limited application.—*L. R. Waldron.*

952. DOWNING, R. G., and L. G. LITTLE. Field experiments with oats. Results of seven years' trials with fertilizers. Glen Innes experiment farm. *Agric. Gaz. New South Wales* 33: 609-613. 1922.—In a 3-year rotation, oats, pasture crop, and maize for silage, fertilizers were applied to the oats at time of planting. The fertilizers—sulphate of ammonia or dried blood, superphosphate, and sulphate of potash—were used singly and variously combined in comparison with check plots. Any combination, without superphosphate, had only slight effect. Fertilizers were applied at the rate of $2\frac{1}{2}$ pounds of nitrogen, 15 pounds phosphoric acid, and 6 pounds potash per acre. Best results were obtained with a complete fertilizer, which increased the yield per acre nearly 40 per cent over the check plot. The annual net monetary gain per acre brought about by the use of a complete fertilizer was \$7.32 in the production of oat hay and \$5.76 for threshed oats.—*L. R. Waldron.*

953. EATON, B. J., F. DELA M. NORRIS, D. H. GRIST, and J. N. MILSUM. [Editors.] *Malayan agriculture.* Dept. Agric. Federated Malay States and Straits Settlements: Kuala Lumpur, 1922.—The handbook indicates the present condition of agriculture in the Malay Peninsula and discusses plans for its improvement.—*I. H. Burkill.*

954. FALKE. Die Bewirtschaftung der Wiesen und Weiden. [The management of meadows and pastures.] *Arbeit. Deutsch. Landw. Ges.* 314. 54-79. 1921.—About $\frac{1}{3}$ the area of cultivated land in Germany is in meadows; the average yield is about 5000 pounds per acre. This low average yield forms the text for a discussion of methods of improving the meadows. The 1st part of the paper is virtually a review of one by Ahr on the fertilizing of

meadows [see Bot. Absts. 9, Entry 285]. The relative merits of seeding on old meadows or plowing and re-seeding are discussed and 3-, 4-, and 5-year rotations are suggested, together with grass and clover seed mixtures for wet, moist, and dry lands. In the 2nd section the author discusses fertilizing pastures, utilization of feed produced, and gives tables and graphs showing gains made by young cattle on stable feed and on pastures, both with and without concentrates. The treatment of sheep pasture is discussed, and grass mixtures for lamb pastures are suggested.—*A. J. Pieters.*

955. GEORGI, C. D. V. Some plant oils of Malaya, their extraction and uses. *Malayan Agric. Jour.* 10: 34-42. 1922.—The oil-yielding plants of the Malay Peninsula are discussed.—*I. H. Burkill.*

956. GOW, C. Wild oats. *Agric. Gaz. New South Wales* 33: 541-544. 1922.—Practical notes on control are given for *Avena fatua*.—*L. R. Waldron.*

957. GRIST, D. H., and SYED ABDUL RAHMAN. The cultivation of Tenggala padi. *Agric. Bull. Federated Malay States* 9: 5-22, 131-153. 1921.—Tenggala padi is rice planted in a rotation on ploughed land, tenggala meaning a plough. The method is the most scientific one used by the Malays. The most common rotation is 4 years cropping and 4 years fallow. The processes of the rotation are described. Improvement must proceed along 3 lines, (a) improvement of the races of rice, (b) manuring for the rejuvenation of the land, and (c) improvement in the methods of manipulation. Catch crops and cover crops are then considered and experiments with them described.—*I. H. Burkill.*

958. GUTHRIE, F. B., and G. W. NORRIS. Notes on wheats entered for the Royal Agricultural Society's show. Easter, 1922. *Agric. Gaz. New South Wales* 33: 497-504. 1922.—One hundred entries were distributed among 11 classes. The wheat variety Quality, from California, had maximum weight of 68 pounds per bushel. Florence stood highest in percentage of flour produced, and Cedar ranked highest in per cent gluten and water absorption. A table is appended giving weight, gluten, and flour strength for the show wheats since 1905.—*L. R. Waldron.*

959. HALL, E. H. Sulphur and nitrogen content of alfalfa grown under various conditions. *Bot. Gaz.* 73: 401-411. 1922.—The analytical method in sulphur analysis used was the "peroxide method" described in the U. S. Bureau of Chemistry Bulletin No. 107. For the sulphate sulphur the Ames method was employed. Total nitrogen was determined by the Arnold-Gunning method and nitrate nitrogen by Koch's modification of the Schlesing-Wagner method. The writer's summary of results is as follows: Alfalfa hay grown in various parts of the U. S. A. shows considerable difference in the percentage of total sulphur content, quite independent of sulphur fertilization. In general, hay from fields with the heaviest crop contains the highest percentage of sulphur. Good to excellent crops of alfalfa hay remove annually from 37 to 90 pounds of sulphur per acre, an amount which would seem far in excess of the amount returned by rain. In some samples all, and in every sample more than 90 per cent, of the total sulphur was in organic form. There was none or little sulphur present in excess of the actual needs as building material.—*B. W. Wells.*

960. HENRICK, J. O. The cultivation of rye. *Agric. Gaz. New South Wales* 33: 483-484. 1922.—The average annual rye acreage in New South Wales is less than 4000. It is used mainly for early winter feed in areas low in production and as a green manure crop on very poor soils. Cultural notes are given.—*L. R. Waldron.*

961. HOUSER, TRUE. New cigar tobacco varieties. *Monthly Bull. Ohio Agric. Exp. Sta.* 6: 135-138. 1921.—A large number of new varieties of tobacco have been bred and tested during the past 18 years at the Ohio Agricultural Experiment Station. Montgomery Seedleaf (hybrid 199), Tall Zimmer (hybrid 224), and Ohio Binder (hybrid 77) have met with much

favor. Characteristics and merits of each variety and tables showing production records are given.—*R. C. Thomas.*

962. HUTCHESON, T. B., and T. K. WOLFE. Silage experiments. Virginia Agric. Exp. Sta. Bull. 227. 16p. 1922.—Silage crops included in the tests were corn, sorghum, soy beans, cowpeas, and millet. Corn and soy beans were superior to the other crops from the standpoint of highest yields of tonnage and total nutrients. Soy beans outyielded corn on the basis of total nutrients, but used alone did not make good silage. It was found that the best silage is obtained with a mixture of soy beans and corn, not more than 1 part of soy beans to 1 part of corn. The 2 crops may be grown together or in separate fields. The best corn varieties for silage purposes are Coker's Prolific, Virginia Ensilage, and Pamunkey Ensilage. The best soy bean varieties for the separate sections of the state are those varieties best adapted for hay production in the section.—Information on culture and harvesting are included.—*F. D. Fromme.*

963. JURITZ, C. F. Prickly pear as a fodder for stock. Union South Africa Dept. Agric. Sci. Bull. 16. 15p. 1920.—Prickly pear is of some value as an accessory food supply during periods of drought, while at other times it is of advantage as a roughage for cattle and ostriches. A number of analyses are given of the green plant, air-dry plant, and fruit. It is not a suitable constituent for ensilage. The spines may be singed off before feeding. A summary is given of experiments with prickly pear as a stock feed in India and Australia. *E. M. Doidge.*

964. JURITZ, F. The nicotine-content of South African tobacco. Jour. Dept. Agric. Union South Africa 4: 552-562, 1922; also South African Jour. Indust. 5: 347-356. 1922.—With the idea of establishing a tobacco extract factory in the Piet Retief district, tables are given of the analyses of tobaccos from different districts. The tobaccos are classed as "heavy" or "light" according to the amount of nicotine contained. The conclusions drawn from the series of investigations are: (1) The heavy South African tobaccos contain in their air dried leaves from 3 to 5 per cent of nicotine; (2) the lighter tobaccos do not as a rule yield much above 2 per cent and frequently fall below 1 per cent; (3) the leaves of the common wild tobacco (*Nicotiana glauca*) apparently contain considerably below 1 per cent nicotine; (4) the most promising results are those obtained from *N. rustica*, the leaves of which have yielded as much as 6 and 8 per cent and even more of nicotine. All parts of the plant contain nicotine, but it is found mainly in the leaves.—*L. Goldblatt.*

965. KERLE, W. D. Farmers' experiment plots. Maize experiments, 1921-22. Upper north coast district. Agric. Gaz. New South Wales 33: 617-621. 1922.—Cooperative trials were conducted upon 9 private farms. The variety Craig Mitchell gave the maximum yield of 84 bushels. Mineral fertilizers gave markedly increased yields over no fertilizer in most cases.—*L. R. Waldron.*

966. KOCH, PIETER. Conservation of soil moisture in relation to Turkish tobacco culture. Jour. Dept. Agric. Union South Africa 4: 319-328. Fig. 1-6. 1922.—In the Western Province, Turkish tobacco is grown as a dry land crop. Owing to the hot and dry climate during the growing season soil moisture must be conserved. This is done by deep ploughing in early winter; by maintaining the productivity of the soil; by increasing the humus content by ploughing in a green crop or stable and kraal manures at least every 4th season; and by frequent and proper cultivation after the crop has been planted. In an appendix the rainfall recorded at Elsenburg during 1919 and 1921 and the average for 17 years are given.—*L. Goldblatt.*

967. LEMMERMANN. Neuzeitliche Düngungsfragen. [Modern fertilizer questions.] Arbeit. Deutsch. Landw. Ges. 314. 80-100. 1921.—The author points out that during the 25 years prior to 1913 the yields of potatoes and grains increased because of the increased use

of fertilizers. From 1913 to 1919 yields declined as follows; bread grains 21.3 per cent, fodder grain 24.2 per cent, potatoes 31 per cent. Besides discussing the use of fertilizer, the author mentions the effect of light on plant growth and advises that drill rows be made north and south so as to receive most light. He reviews the work of Borneman and of himself on fertilizing with carbon dioxide [see Bot. Absts. 8, Entry 32], but the main part of the paper is concerned with a discussion of the profitability of using nitrogen, phosphoric acid, and potash at prevailing prices of fertilizers and of grains.—*A. J. Pieters.*

968. LITTLE, L. G. Field experiments with sunflowers. A comparison with maize for silage. Glen Innes experiment farm. Agric. Gaz. New South Wales 33: 622-624. 1922.—Each crop was sown at the rate of 15 pounds of seed per acre in 35-inch rows using 70 pounds of superphosphate per acre. Sunflowers were cut in full flower and maize at the best silage stage. Sunflowers yielded 7 tons and maize 3.8 tons per acre. According to analyses of the silage, maize carried more water, less protein, less ether extract, and more fiber than the sunflowers.—*L. R. Waldron.*

969. McCauley, C. Field experiments with wheat, 1921. Cowra experiment farm. Agric. Gaz. New South Wales 33: 545-548. 1922.—Wheat was planted both early and late for grain and hay. Cowra No. 29 yielded highest for grain in the early planting, and in the late planting trial, Canberra held this rank in grain production.—*L. R. Waldron.*

970. MAINWARING, C. The common sunflower (*Helianthus annuus*). Rhodesia Agric. Jour. 19: 295-301. Fig. 1-2. 1922.—The chemical composition and the methods of cultivation of the sunflower are given. The sunflower is a dry-land crop and is more resistant to heat and drought than maize. Where the first consideration is to produce a crop either for cash or for feeding purposes, maize is considered more profitable, especially in the richest districts; but in drier portions of Rhodesia sunflowers are more likely to flourish and prove profitable.—*L. J. Goldblatt.*

971. MAINWARING, C. The ground nut or monkey nut. Rhodesia Agric. Jour. 19: 150-158. Pl. 1-4. 1922.—The author discusses the cultivation of *Arachis hypogaea*. Climatic conditions over the whole of Rhodesia are favorable for its growth. Spanish Bunch and Virginia Bunch have proved superior croppers and best suited to local conditions over a number of seasons. The oil, which is obtained in large quantities, is used in the preparation of food stuffs, leather dressing, furniture creams, hair and cosmetic oils, etc., and for illumination. Shelled ground nut oil-cake contains 10 per cent of fat and 46 per cent of albuminoids (protein), thus making it a highly concentrated cattle feed.—*L. J. Goldblatt.*

972. MASCHHAUPT, J. G. De invloed van grondsoort en bemesting op het gehalte onzer landbouwgewassen aan stikstof en aschbestanddeelen. [Influence of soil and fertilizing on nitrogen and ash constituents.] Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefsta. 25: 115-130. 1921.—In these experiments of 1918, winter wheat was used on experimental plots representing 5 kinds of soil,—heath sand, peat-moor, marsh soil, gravel-sand, and clay soil. Whereas the influence of nitrogen fertilizers on nitrogen and ash of the plants had been studied earlier, the present investigations were on the influence of potassium and phosphoric acid fertilizers. Four procedures were used: (1) nitrogen only, (2) complete fertilizer (nitrogen, potassium, phosphorus), (3) nitrogen and potassium, (4) complete fertilizer with double portion of potassium. The following observations were made: The greatest weight (79.63 kgm.) per hectoliter wheat was obtained from marsh soil, the smallest (76.58 kgm.) from gravel-sand; the weights from peat-moor, heath sand, and clay were respectively 78.36, 77.16, and 77.14 kgm. Soil seems to have a distinct influence on weight of the grain. Grain from marsh soil was glassy and from gravel-sand, mealy,—a difference undoubtedly connected with the high nitrogen content of the former and the low nitrogen content of the latter. Doubling the potassium in the complete fertilizer was without effect. In heath sand, just as much N and K₂O were taken out of the soil as were added in the fertilizers, whereas in the other soils

much more was taken out than put in. Less than half the added phosphorus was taken out. The amounts of silica taken from gravel-sand and clay are considerable. Much less N is taken up than is usually supposed.—In another experiment, a higher calcium carbonate content of the soil had no influence. Beets grown on "young" clay rich in CaCO_3 had a higher N, P_2O_5 , MgO, and K_2O content, a very much higher Cl and Na_2O content, but a much lower CaO content than those grown on "older" clay soil containing less CaCO_3 . The same relation was found by an analysis of oat plants grown on "schuimaarde" (approximately $\frac{1}{4}$ of which is CaCO_3) and "old" clay soil. A very much greater nitrogen content was found, partly as nitrates and partly as ammonia. The CaO contents in comparison with other constituents were quite low. MgO was taken up in relatively increased amount, as was nitrogen.—A German résumé concludes the paper.—*Peter J. Klaphaak.*

973. MOE, CARL. Utilization of lime sludge. Paper 29¹¹: 11-12. *Fig. 1-2*. 1921.—Lime sludge from a sulphate pulp mill gave very much better results than commercial limestone when applied to fields in preparation for planting of corn and clover.—*H. N. Lee.*

974. MOOMAW, LEROY. Report of the Dickinson substation for the years 1920 and 1921. North Dakota Agric. Exp. Sta. Bull. 160. 32 p. 5 fig. 1922.—Results of 13 years' cropping are given for spring wheat, oats, and barley on disced corn ground; on spring-plowed grain-stubble land in comparison with fall-plowed; after clean fallowed land; and following a green manuring crop. The following are the respective average yields for spring wheat from the 5 methods: 18.7, 15.2, 15.6, 21.1, and 16.8, bushels per acre. The use of a bare summer fallow has not been justified and the use of a green manuring crop has shown no positive results.—Wheat continuously cropped for 13 years averaged 13 bushels per acre in comparison with 22.5 bushels from wheat alternately cropped with summer fallow.—During 15 years, including 1 year of hail loss, shelled corn has averaged 11.3 bushels per acre. The average for 8 of these years, when corn was mature enough to husk, was 21.2 bushels.—Monad and Kubanka durum wheats have significantly outyielded the best varieties of common wheats. The best varieties of winter wheat have yielded considerably less than varieties of common spring wheat.—Dakold rye is more productive than other varieties.—Midseason oats have outyielded early and late varieties.—The 2-rowed barleys Hannchen and Swan Neck [Svanhals] have outyielded all 6-rowed varieties.—Proso millet is less productive than other grain crops.—Notes and yields are given of grasses, alfalfa, field peas, roots, and other forage crops.—In a 5-year test Burbank and Irish Cobbler outyielded other potato varieties.—*L. R. Waldron.*

975. NEWTON, W. Why grow sweet clover? Agric. Jour. [British Columbia] 7: 106. 1922.—Sweet clover has not given very good results in the coast regions, perhaps because the soils are usually slightly acid. It is better adapted to conditions in the interior of the province.—*J. W. Eastham.*

976. OLSON, EDGAR. The demonstration farms, 1921. Sixteenth annual report. North Dakota Agric. Exp. Sta. Bull. 163. 54 p. [1922].—Detailed yields and culture methods, with costs of production, are given for 20 demonstration farms for 1921. The crops dealt with are durum and common wheat, oats, barley, corn, flax, potatoes, alfalfa, and sweet clover. A 10-year summary of results is given for the Lakota farm. Alfalfa on this farm has made a greater net return than any other crop, including wheat.—*L. R. Waldron.*

977. OOSTHUIZEN, J. DU P. Different methods of curing tobacco. Jour. Dept. Agric. Union South Africa 5: 131-150. *Fig. 1-12*. 1922.—The article discusses the different methods of curing tobacco (air-curing, sun-curing, fire-curing, and flue-curing) and its preparation for market. Most of the tobacco grown in the Union is air-cured, which is hazardous because of the weather. The quality of the tobacco produced in the Union can be improved, although the value of good quality leaf is sometimes reduced during curing. The climate of South Africa is favorable for air-curing, although during the wet seasons much better results could be obtained by the use of artificial heat in air-curing or by flue-curing.—*L. Goldblatt.*

978. PARISH, E. **Agricultural experiment, its design and interpretation.** Union South Africa Dept. Agric. Sci. Bull. 22. 21 p. 1922.—The variation in yield of single plots similarly treated is so great as to render valueless comparisons made from the result of single plot trials; similarly with experiments with small numbers of animals, owing to the high variation of the individual. Replication in agricultural experiments is absolutely necessary. In field trials the replication of the plots must be systematic and so designed as to obviate the effect of progressive differences in the soil; no appreciable increase in reliability is gained by enlarging plots beyond $\frac{1}{4}$ of an acre.—*E. M. Doidge.*

979. PARISH, E. **Causes of the high cost of production of maize and the remedy.** Jour. Dept. Agric. Union South Africa 4: 417-429. Pl. 1-3. 1922.—The high cost of maize production may be considered under the following heads, for each of which the remedy is given: (1) low yields; (2) high cost of labor and high cost of grazing of oxen, costly methods of ploughing, and method of payment of native labor; (3) lack of diversity of crops resulting in an uneconomical use of labor; (4) high cost of management; (5) over capitalization in land or men resulting in excessive overhead charges; (6) farming on borrowed capital at high rates of interest; (7) non-use of fallows and winter-ploughing system of farming; (8) faulty utilization of farm products; (9) other considerations including area of land worked per implement; life of implements; investment per 100 acres of maize; and ingenuity.—*L. Goldblatt.*

980. PHILLIPS, E. P. **A possible cattle food (seeds of *Sesbania cinerascens* Melw. and *S. mossambicensis* Klotz.).** Jour. Dept. Agric. Union South Africa 4: 361-365. Fig. 1. 1922.—Twenty-three species of *Sesbania* are recorded in Africa, of which 6 occur in South Africa. Chemical analyses are given of *S. mossambicensis* and *S. cinerascens*, which have possibilities as feeding stuffs of high feed value if they prove harmless to animals. Merchants report that *S. mossambicensis* might be utilised in place of peas, lentils, and millet.—*L. Goldblatt.*

981. PITT, J. M. **Farmers' experiment plots. Potato trial, 1921-22. Central coast.** Agric. Gaz. New South Wales 33: 471-475. 1 fig. 1922.—Cooperative experiments were conducted by 13 farmers. Application of phosphatic fertilizers gave an economic increase of yield. Varieties Carman and Up-to-date gave comparatively high yields. Spacing and size-of-tuber experiments were conducted on 1 farm.—*L. R. Waldron.*

982. POLE EVANS, I. B., and K. A. LANSDSELL. **The Galinsoga weed (*Galinsoga parviflora* L.).** Union South Africa Dept. Agric. Bull. 1920⁷: 1 pl. 1920.—The plant is described and illustrated by a colored plate.—*E. M. Doidge.*

983. POLE EVANS, I. B., and K. A. LANSDSELL. **The purple stinkweed (*Datura tatula*).** Union South Africa Dept. Agric. Bull. 1920⁸: 1 pl. 1920.—The plant is described and illustrated by a colored plate.—*E. M. Doidge.*

984. POLE EVANS, I. B., and K. A. LANSDSELL. **The sow thistle (*Sonchus oleraceus*).** Union South Africa Dept. Agric. Bull. 1920⁸: 1 pl. 1920.—The plant is described and illustrated.—*E. M. Doidge.*

985. POLE EVANS, I. B., and K. A. LANSDSELL. **The upright star-burr (*Acanthospermum hispidum* D.C.).** Union South Africa Dept. Agric. Bull. 1920⁸: 1 pl. 1920.—The plant is described and illustrated by a colored plate. Means of eradication are suggested.—*E. M. Doidge.*

986. PRIDHAM, J. T. **Climate in our relation to our wheat.** Agric. Gaz. New South Wales 33: 469-470. 1922.—Certain areas of New South Wales are suitable for successful growth of semi-hard wheats such as Hard Federation. Since such varieties bring better prices overseas it is suggested that farmers might capitalize this fact where climatic conditions warrant.—*L. R. Waldron.*

987. PRIDHAM, J. T. Oats on the wheat farm. *Agric. Gaz. New South Wales* 33: 615-616. 1922.—Storage of oats on farms is discussed.—*L. R. Waldron.*

988. RINDL, M. Mafura tallow. A product of the nuts of *Trichilia emetica*. *South African Jour. Indust.* 5: 415-423. 1922.—Mafura nuts are a valuable potential oil seed of which fairly large quantities are available from trees growing wild in Portuguese East Africa. The possibility of profitably cultivating the tree in places easily accessible by rail or barge is suggested. The high melting point of the tallow makes it valuable for the candle industry, but its value as a soap stock, as well as for food and other purposes, still needs investigating. The entire export of this nut from Portuguese East Africa in 1913 was valued roughly at £45,000.—*Sydney M. Stent.*

989. RITTER, KURT. Deutschlands Wirtschaftslage und die Produktionssteigerung der Landwirtschaft. [The economic condition of Germany and the increase in agricultural productivity.] *Landw. Jahrb.* 57: 285-397. 1922.—A detailed study of the present economic condition in Germany is presented with the conclusion that only an increased agricultural productivity will save Germany in the next few years from famine. The author discusses in detail the condition of agricultural economy in relation to an increase in productivity and suggests means for bringing about the latter.—*Selman A. Waksman.*

990. SCHOLER, J. K. Field experiments with wheat, 1921. Coonamble experiment farm. *Agric. Gaz. New South Wales* 33: 477-482. 1922.—Trials were duplicated on the farm upon red and black soils. Varieties sown on the heavy black soil of the open plain country had their yields much reduced because of attacks of rust [*Puccinia graminis*]. Varieties sown on the red sandy loam of the wilga and pine country did not suffer from rust attacks.—*L. R. Waldron.*

991. SEELHORST, VON. Ackerbaufragen. [Problems in field culture.] *Arbeit. Deutsch. Landw. Ges.* 314. 3-24. 1921.—The author discusses the problems of green manuring, artificial fertilizers, and cultivation with various tools and machines.—*A. J. Pieters.*

992. SHEPHERD, A. N. Farmers' experiment plots. Green fodder trials, 1921-22. Murrumbidgee irrigation areas. *Agric. Gaz. New South Wales* 33: 639-641. 1922.—Notes are given on manurial and variety trials with maize, sorghum, and Sudan grass.—*L. R. Waldron.*

993. SHEPHERD, A. N. Fodder crops for dairy farmers. Murrumbidgee irrigation area. *Agric. Gaz. New South Wales* 33: 625-628. 1922.—Practical cultural notes are given for various fodder crops for the region indicated.—*L. R. Waldron.*

994. SKIBBE, ARTHUR, and JACQ P. F. SELLSCHOP. Some fodder plants and feeding stuffs. Their culture and chemical composition. *Jour. Dept. Agric. Union South Africa* 4: 338-349. Pl. 1. 1922.—The results are given of experiments conducted at Potchefstroom on the adaptability of various uncommon forage crops to the soil and climate of this area of the Transvaal. The description, uses, etc., and tables showing the chemical composition and cultural methods are given of the following: Dhal bean (*Cajanus indicus*), chick pea (*Cicer arietinum*), Sesbania (*Sesbania aculeata*), Tepary beans (*Phaseolus acutifolius*), tick bean (*Vicia Faba*), peanuts or monkey-nuts (*Arachis hypogaea*), Sudan grass (*Sorghum sudanense*), and Napier fodder (*Pennisetum purpureum*).—*L. Goldblatt.*

995. SOUTH, F. W. The possibilities of developing roselle fibre as a cottage or other industry in the F.M.S. *Agric. Bull. Federated Malay States* 9: 23-26. 1921.—The author describes the growth of *Hibiscus Sabdariffa* var. *altissima* and its possibilities as a fiber crop.—*I. H. Burkill.*

996. SPRING, F. G. Cover-crops and clean-weeding. The butterfly pea (*Centrosoma Plumieri*) and giant mimosa (*Mimosa incisa*). *Agric. Bull. Federated Malay States* 9: 169-

174. 1922.—The action of these 2 plants in preventing and in keeping down weeds is described. The Sarawak bean (*Dolichos Hosei*) is more partial to particular soils. *Dolichos biflorus* continues upon the ground for a shorter period.—*I. H. Burkill*.

997. STEVENS, O. A. North Dakota weeds. North Dakota Agric. Exp. Sta. Bull. 162. 44 p., 45 fig. 1922.—Nine pages are devoted to a general discussion of weeds. The remainder of the bulletin is devoted to individual discussion and illustration of 30 important weeds of the state, each considered under description, distribution, habits, and control.—*L. R. Waldron*.

998. TICE, C. Seed-certification work reviewed. Agric. Jour. [British Columbia] 7: 102-103. 1 fig. 1922.—The work done in British Columbia on the certification of seed potatoes in 1921 is summarized.—*J. W. Eastham*.

999. WENHOLZ, H. Alteration of names of maize varieties. Agric. Gaz. New South Wales 33: 544. 1922.—The varieties from the U. S. A. known as Northwestern Dent and U. S. 133 are renamed Sundown and Early Morn, respectively.—*L. R. Waldron*.

1000. WHITTET, J. N. A new method of harvesting grain sorghum seed. Agric. Gaz. New South Wales 33: 556-557. 3 fig. 1922.—Sorghum was harvested and threshed by the reaper-thresher in 1 operation.—*L. R. Waldron*.

1001. WHITTET, J. N. Kikuyu grass (*Pennisetum clandestinum*) in Queensland. Agric. Gaz. New South Wales 33: 578. 1922.—A farmer's note is given on the plant under cultivation.—*L. R. Waldron*.

1002. ZADE. Futterbau und Futterpflanzen Züchtung. [Forage culture and the breeding of forage plants.] Arbeit. Deutsch. Landw. Ges. 314. 43-53. 1921.—This general paper calls attention to the importance of high grade seeds in the production of forage crops. The author mentions several registered strains and discusses the causes for the lack of demand for highly bred forage crop seeds. Some suggestions are made for growing and harvesting grass seed.—*A. J. Pieters*.

1016. DALRYMPLE-HAY, R. Report of the Forestry Commission for New South Wales for the year ending June 30, 1921. 18 p. Sydney, New South Wales, 1921.—During the year 1,096 acres were planted at a direct cost of £3,160, and an additional 1,705 acres were prepared for planting. Substantial progress was also made in marking boundaries of State forests, constructing roads and fire breaks, and permanent improvements necessary for administrative purposes. The area of forest under systematic fire protection is 759,000 acres out of a total of 5,194,000 of state forests, plus 1,536,000 acres of timber reserves. During the year 140,944 acres were put under working plans, bringing the total to date up to 875,037, and 36,000 acres of natural forest were treated for regeneration. The gross revenue was £190,742, the administrative expense £57,835, and expenditure on forest works £104,782. The value of imported timber was £2,073,046, and of exported £464,725. Detailed data on all activities and costs are given in a comprehensive series of tables. The total production of native timber was 155,114 M superficial feet, and total consumption 352,882 M. Progress has been made in botanical studies, in securing data on valuable exotics for introduction, and on use of certain woods for pulp. A valuable feature of the report is the graphic summary of the principal data.—*S. B. Show.*

1017. DURLAND, WILLIAM DAVIES. The forests of the Dominican Republic. *Geog. Rev.* 12: 206-222. 1922.—Fully $\frac{3}{4}$ of the 19,000 square miles of the republic can be classed as timberland. The island is rough and rugged with 4 principal mountain ranges, the highest of which attains an elevation of over 8000 feet. Rainfall is heavy (60 inches + per year) and well distributed. The forests are generally tropical in character and, except for a few of the most valuable species, are little known. A generalized type map recognizes the following principal cover types: (1) evergreen hardwood, (2) partly evergreen hardwood, (3) pine, (4) thorn, (5) savanna, (6) mostly deciduous, (7) littoral hardwood. Much of the exploitation has been in the partly evergreen hardwood type, and especially in the pine type. The general characters of each type are described. The pernicious practice of "comico making," or clearing of forest for temporary agricultural use, is of considerable importance in the republic. A partial list of the trees of the island is included.—*S. B. Show.*

1018. ELLIS, L. MACINTOSH. New Zealand Forest Service. Report for the year ending March 31, 1921. 20 p. Wellington, New Zealand. 1921.—The year is characterized as one of stock-taking, of study of conditions and problems, and the creation of the Forest Service for administration of forests and woodlands, which now total 6,800,000 acres. Seven forest

conservation regions have been established. The policy contemplates scientific management, systematic protection, planting on all Crown forest lands, establishment of a forest school, and promotion of research. The Forest Service at present has a force of 97. General reconnaissance of several of the principal mountain ranges was made. Receipts and expenditures are given in detail, and a general summary from 1896 to date showing total revenue at £32,040 per year against £23,570 expense. A total of 2,500,000 acres of timberland has been destroyed by fire; this loss continues at the annual rate of 50,000 acres. A total of 38,461 acres has been planted since 1896. Total production of lumber for the year was 309,162 M superficial feet. It is urgently recommended that all available Crown forest land be dedicated as provisional state forest. Detailed summaries of the afforestation work show special measures taken to protect plantations from fire, that 520,000 trees were planted by ranchers, etc., during the year, while 2,877,000 were planted on state forests on 1,381 acres. Data on export and import of timber are given.—*S. B. Show.*

1019. GRIFFITH-BOSCAWEN, ARTHUR, and G. G. LEVESON GOWER. *The Ninety-ninth Report of the Commissioners of H. M. Woods, Forests and Land Revenues [Great Britain] for the Year ending March 31, 1921.*—The total income for the year was £11,234, 645, of which £100,494 was from timber, the balance from agricultural and house property, mines, interest, etc. The expenditures were £549,314, of which £68,365 was for planting and preparation of timber for sale. In accordance with various acts of Parliament, expenditures, incomes, leases, rents, etc., are given in great detail. There is no information of consequence on progress of forestry; the report gives only business details.—*S. B. Show.*

1020. HOWE, C. D. *The performance of culled acre.* Paper 27²³: 11-13. 1921.—In 1 acre taken as an average sample of a large area the following conditions have been determined. About 50 years ago 5 white pine trees yielded 2,500 feet of lumber. There is no white pine in any stage of growth now. Two cuttings 26 and 16 years ago yielded 6.5 cords of pulpwood. Depletion of the growing stock during logging, absence of proper gradations of diameter classes, absence of adequate reproduction, and influence of hardwoods make it improbable that such a yield will be repeated naturally. Eight years ago 2.5 cords of balsam fir pulpwood were cut and 24 years after that cutting it is estimated that 3.5 cords will be available. Proper handling will allow young spruce and balsam trees to develop a good commercial stand.—*H. N. Lee.*

1021. KINDLE, E. M. *Notes on the forests of southeastern Labrador.* Geog. Rev. 12: 57-71. 1922.—There is sharp contrast between the desolate, treeless shore strip, due to year-round presence of ice in adjacent waters, and the heavily forested interior. The seaward edge of the forest consists of stunted and dwarfed black spruce (*Picea mariana*), but the timber increases in height inland to an average of 50-60 feet. Much of the timber is large enough for lumber production, but the bulk is more suitable for pulpwood. Exploitation has just begun. Data are given on individual large trees.—*S. B. Show.*

1022. MARTIN-ZEDE. *De l'influence de l'orientation sur les succès de la transplantation des arbres.* [The influence of orientation on the success of transplanting trees.] Compt. Rend. Acad. Sci. Paris 174: 61-63. 1922.—Work done on the island of Anticosti with species of fir, larch, spruce, and birch showed that trees do better if transplanted with their south side towards the south etc.; 50 per cent were found to be successful with this method as opposed to 6-8 per cent set without reference to orientation.—*C. H. Farr.*

1023. NELSON, MAURICE. *The utilization of jack pine in the manufacture of newsprint.* Paper Indust. 3: 1510-1513. 1922.—A complete description is given of actual use of *Pinus divaricata* in the manufacture of sulphite and groundwood pulp.—*H. N. Lee.*

1024. NOVAKOVSKY, STANISLAUS. *Climatic provinces of the Russian far east in relation to human activity.* Geog. Rev. 12: 100-115. 1922.—Forests of the region are described incidentally to a study of climate.—*S. B. Show.*

1025. SUTERMEISTER, E. The use of rotten and stained wood for making sulphite pulp. *Pulp and Paper Mag.* 20: 513-514. 1922.—Experiments showed that partially rotted spruce wood which is still moderately firm will yield 767 pounds of pulp per 100 cubic feet of actual wood, while sound spruce wood yields 956 pounds. The fiber from the rotted wood was weak and of very poor color. The outer part of spruce logs, especially if river driven, are discolored to a grayish brown; there is no decrease in yield of fiber due to this, but the pulp from the discolored wood requires much more bleach to produce a good white pulp.—*H. N. Lee.*

1026. WEST, C. J. Paper making trials at the Imperial Institute. *Paper* 28¹¹: 28-31; 28¹²: 25-27, 29. 1921.—Work done since about 1912 at the Imperial Institute, South Kensington, is reviewed.—*H. N. Lee.*

1027. WILLIAMS, C. O. The composition of Natal wattle bark. III. Union South Africa Dept. Agric. Bull. 1920¹: 14 p. 1920.—Mature wattle bark loses about $\frac{1}{2}$ its weight during drying. The total amount of bark and of tanning material increases with the age of trees, but the percentage of tanning matter is approximately the same. Coast trees mature more rapidly but are inferior to those grown in the Midlands. In the commercial samples of solid wattle extracts manufactured in Natal, the proportion of tanning matter varies from 59 to 67 per cent.—*E. M. Doidge.*

GENETICS

1028. ANONYMOUS. Breeding wheat to resist rust. *Northwest. Miller* 126: 296. 1921.—The writer reviews addresses by W. P. THOMPSON and W. P. FRASER at Saskatoon, April, 1922. Thompson has tested, in field and greenhouse, hundreds of varieties from all parts of the world. Less than a dozen showed true resistance and none of these was a common wheat of spring type. Crossing experiments showed that resistance is inherited like other agronomic characters. A number of hybrids appeared resistant until 1919, when attacked by forms of stem rust not previously encountered at Saskatoon. Further breeding work, to secure resistance also to these forms of rust is being carried on.—Fraser is investigating methods of over-wintering of stem rust to determine the origin of spring infection. He has no direct evidence that the spring infection arises from the barberry. Eight forms of stem rust have been isolated in Canada and there is evidence of several others. In connection with the rust investigations, rows of varieties of common spring wheat, durums, and emmers, which are known to have some resistance, were seeded at various stations throughout western Canada.—*J. B. Harrington.*

1029. ANONYMOUS. The genetics of vegetables. *Gard. Chron.* 71: 146. 1922.—The Royal Academy of Belgium offers a triennial prize of 2,500 francs, to be known as the Prix Joseph Schepkens, for the best experimental work on the genetics of vegetables.—*L. R. Detjen.*

1030. ANONYMOUS. The value of selection and breeding. *Agric. Gaz. New South Wales* 33: 732. 1 chart. 1922.—Results from Hawkesbury Agricultural College egg-laying contests for 20 years are shown graphically for (a) 10 leading pens (60 birds), (b) 10 lowest pens (60 birds), and (c) for the whole competition. Gradual increase in eggs laid is noted.—*L. R. Waldron.*

1031. AAMODT, OLAF S. Correlated inheritance in wheat of the winter-spring habit of growth and rust resistance. *Phytopathology* 12: 32-33. 1922.—Kanred, a winter wheat, is resistant to several biologic forms of stem rust to which Marquis, a spring wheat, is sus-

ceptible. Seed of an F_2 Marquis-Kanred cross was sown in the spring at St. Paul, Minnesota, and the resulting plants placed in 9 groups, according to time of heading. Seven of these 9 groups set seed and were tested in F_3 . All individuals of the earliest-heading F_2 group bred true for spring habit. In the other 6 groups the percentage of spring plants in F_3 was in direct relation to the time of heading of the F_2 group. The segregation for rust, on F_3 seedlings with a single known biologic form, approximated a ratio of 3 resistant to 1 susceptible. This ratio was about the same for all heading periods.—J. A. Clark.

1032. AAMODT, OLAF S. The inheritance of resistance to several biologic forms of *Puccinia graminis tritici* in a cross between Kanred and Marquis wheats. *Phytopathology* 12:32. 1922.—Kanred, a winter wheat, was found immune, and Marquis, a spring wheat, susceptible. In a cross between these varieties, greenhouse studies of F_3 seedlings proved the plants to be either immune or completely susceptible. There were no intermediates. Immunity was dominant. The results of inoculation experiments indicated that apparently a single factor determines the reaction to several biologic forms. Families homozygous for spring habit and rust resistance were obtained in the F_3 generation.—J. A. Clark.

1033. ARMSTRONG, S. F. The Mendelian inheritance of susceptibility and resistance to yellow rust (*Puccinia glumarum*, Erikss. et Henn.) in wheat. *Jour. Agric. Sci.* 12: 57-96. 1922.—Work of other investigators, indicating that susceptibility and resistance to *Puccinia glumarum* is a heritable character in wheat, is substantiated. Results indicate a single factor difference. In a cross of a susceptible wheat \times resistant wheat, the F_1 gave susceptibility of an intermediate nature.—Environmental conditions materially influence the degree of infection, but the relative difference in susceptibility and resistance remains approximately the same. Evidence is presented that genetic factors for other plant characters may modify the expression of the factor for susceptibility and resistance.—Selection from a variety containing both resistant and susceptible plants isolated 2 pure strains, one homozygous for resistance, the other homozygous for susceptibility. Both selections appeared to be morphologically identical, differing only in resistance to rust. Under rust conditions the resistant strain gave about 50 per cent higher yield than the susceptible strain.—H. E. Brewbaker.

1034. BAUR, ERWIN. Die wissenschaftlichen Grundlagen der Pflanzenzüchtung. Ein Lehrbuch für Landwirte, Gärtner und Forstleute. [The scientific principles of plant breeding. A text book for agriculturists, gardeners, and foresters.] 1st & 2nd ed., v + 120 p., 6 pl. 11 fig. Gebrüder Borntraeger: Berlin, 1921.—In this popular presentation of the fundamentals of genetics applied to agriculture, the topics of variation, reproduction, inbreeding, and natural selection are covered briefly. Variations are classified as modifications due to environment, combinations following hybridization, and mutations. Reproduction is classified as asexual, sexual, and parthenogenetic. The reducing effects of inbreeding are made clear by data from the snapdragon and illustrated by the comparative size of 3 generations of inbred kale plants. Natural selection is shown to adapt various strains of cultivated plants to different conditions. Cultivated plants are classified into 4 groups: vegetatively reproduced, naturally self-fertilized, and naturally cross-fertilized plants which can be artificially inbred and those which can not. The application of methods of improvement to these 4 groups is illustrated by systems of breeding representative plants in each group. [See also Bot. Absts. 11, Entry 2472.]—D. F. Jones.

1035. BECKER, J. Über Vererbungsgesetze bei Gurken. [On laws of inheritance in cucurbits.] *Zeitschr. Pflanzenzücht.* 8: 290-293. 1922.—Attempts to produce xenia between squashes and melons through artificial cross pollination completely failed. Reports of xenia between these plants are probably due to the melon-like taste, odor, and color sometimes noted in very ripe squashes.—In a cross between a squash with short and yellow fruits and another with long and white fruits, the F_1 was found to have white fruits of intermediate length. The F_2 fruits were approximately 9 white and long; 3 yellow and long; 3 white and short; and 1 yellow and short. The F_1 and F_2 were raised in relatively poor soil, so that plants with the

fruit-size of the large parent (which normally grows in very rich soil) never reappeared.—*E. W. Sinnott.*

1036. BLARINGHEM, L. Note préliminaire sur l'hérédité de la prolifération et de la duplication chez *Cardamine pratensis*. [Preliminary note on the heredity of proliferation and double flowers in *C. pratensis*.] Bull. Soc. Path. Veg. France 9: 138-144. 1 fig. 1922.—The author crossed the common *Cardamine pratensis* L. with a double-flowering form, each strain having been derived from a single individual. The F_1 progeny were similar, with dominance of the single flower character. Eight F_1 plants gave only sterile fruits, while 101 gave fruits with seeds. Of the 101, 94 appeared normal; while 7 gave fruits all or in part proliferated, their inflorescences appearing as a mosaic made up in part of an inflorescence with fruits of the common *Cardamine* and in part of an inflorescence with proliferated ovaries. In the same ovary, the two characters may be juxtaposed. This is an example of Naudinian heredity.—*J. Dufrenoy.*

1037. BLOSSFELD, ROBERT. Die hauptsächlichsten Orchideen-Hybriden. [The principal orchid-hybrids.] Gartenwelt 25: 122-124, 155-157. 1921.—Examples of bigeneric crosses are *Adioda* = *Ada* × *Cochlioda*; *Anoetomaria* = *Anoetochilus* × *Haemaria*; *Brassocattleya* = *Brassovola* × *Cattleya*; *Epicattleya* = *Epidendrum* × *Cattleya*; *Oncidioda* = *Oncidium* × *Cochlioda*; *Schombocattleya* = *Schomburgkia* × *Cattleya*; *Zygobatemannia* = *Zygopetalum* × *Batemannia*. The following are trigeneric: *Brassocattlaelia* is a product from *Brassovola*, *Cattleya*, and *Laelia*; *Diacattlaelia*, from *Diacrum*, *Cattleya*, and *Laelia*; *Lowaria*, from *Brassovola*, *Sophronitis*, and *Laelia*; *Vuylstekeaeria*, from *Cochlioda*, *Miltonia*, and *Odontoglossum*.—Most *Brassocattleyas* which are products between *Brassovola Digbyana* and either *Cattleya aurea*, *C. Dowiana*, *C. Gaskelliana*, *C. labiata autumnalis*, *C. Mendeli*, *C. Mossiae*, *C. speciosissima*, or *C. trianae*, and the natural hybrid *C. Hardyana* are characterized by large flowers and very large and fringed labellum. *Brassovola Digbyana* usually produces 1 flower on each stalk, *Cattleya* of the *Labiata* group usually 3-4, and *Brassocattleyas* usually 2.—In crosses between *Brassovola Digbyana* and *Cattleyas* many characters of the former are dominant; in crosses between *B. Digbyana* and *Cattleya Dowiana* and its variety *aurea* many characters of the latter are dominant, especially the yellow color of the sepals and petals and the deep purple of the labellum. One cross between *C. Mossiae* and *C. gigas* does not flower, another flowers about July 1, and another about February. *C. Fredeekiae* (= *C. Mossiae* × *C. aurea*) flowers in the spring. The following results of crosses between white-flowering *Cattleyas* were obtained: *C. Mossiae alba* (*Wagnerii*) with *C. Gaskelliana alba* and *C. intermedia alba* produces only white flowering individuals. *C. Gaskelliana* × *C. intermedia alba*, *C. Schrosderae alba*, or *C. Harrisoniana alba* produces only lavender colored offspring. *C. Mossiae alba* (*Wagnerii*) × *C. gigas* Frau Melanie Beyrodt (with white sepals and petals and purple labellum) produces some albinos and some lavender flowers. *C. gigas* Frau Melanie Beyrodt × *C. aurea*, *C. Warneri alba* × *C. Gaskelliana alba*, and *C. gigas* Frau Melanie Beyrodt × *C. Gaskelliana alba* give the same results. The crosses *C. labiata alba* × *C. labiata alba* (*Cookson*) and *C. intermedia alba* × *C. Warneri alba* (*Peeters*) produce lavender colored flowers. *Laelia purpurata* and *L. tenebrosa* are generally used in crosses with *Cattleya*. Yellow flowered *Laeliocattleyas* are obtained by using as one parent *Laelia cinnabarina*, *L. flava*, *L. harpophylla*, or *L. xanthina*. *Saphronitis grandiflora*, with pure red flowers, has much influence on crosses with *Laeliocattleya*. *Epidendrum* has been crossed with *Saphronitis* (= *Epiphronitis*).—*J. C. Th. Uphof.*

1038. BRINK, R. A. The genetic basis for improvement in self-fertilized crops. Sci. Agric. 2: 83-87. 1921.—Essential features of the paper are (1), a review of the development of genetic thought as it has affected breeding practice with autogamous plants; (2) a discussion of a heretofore unemphasized property of pure lines.—Assuming that degressive mutations in pure lines occasionally occur, it is shown mathematically how the degressive strain gradually diminishes in proportion and thereby tends to be eliminated from the mixture with the original pure line.—*H. E. Brewbaker.*

1039. BUCHHOLZ, JOHN T. Developmental selection in vascular plants. Bot. Gaz. 73: 249-286. 28 fig. 1922.—Developmental selection consists of interovular (between ovules in same ovary) selection, embryonic (between embryos) selection, gametophytic (between male gametophytes such as pollen tubes and female gametophytes in same ovule) selection, and gametic (between gametes) selection. These are distinguished from natural selection. Selection between vegetatively branching parts is held to be intermediate, i.e., part developmental and part natural selection. Developmental selection as treated by the author has naught to do with such theoretical considerations as that of germinal selection. The data of conspicuous cases of polyembryony (sporophyte) and gametophytic selection are brought together. The author states that a good selective process has the following requirements: It should (1) start the competition simultaneously, (2) take place under uniform conditions, (3) measure comparable merit, and (4) rigidly eliminate the great majority that fall below the standard. The author holds that developmental selection much excels natural selection in meeting these requirements. Developmental selection may act upon very small quantitative characters, which situation may furnish a basis for selection of larger and more significant characters through linkage. Thus "the mechanism of developmental selection looks very promising as a means of accounting for many orthogenetic phenomena." Further, developmental selection may have a prominent rôle to play in the phenomena of variation and mutation. As regards the latter the discovery and recognition of them "depends upon whether they reappear in the next life cycle and thus pass the censorship of the developmental selection machinery."—*B. W. Wells.*

1040. COBB, FRIEDA. A case of Mendelian inheritance complicated by heterogametism and mutation in *Oenothera pratincola*. Genetics 6: 1-42. 1921.—A number of strains, all morphologically alike, of *O. pratincola* have been isolated. Strain E is genetically different from the other strains, of which strain C is a typical example. Strain E produces 4 types of revolute-leaved mutations not produced by other strains. Mut. *formosa* E is the most fertile and typical of the revolute-leaved series. Reciprocal crosses of mut. *formosa* E with f. *typica* E show matroclinic inheritance. Strain C \times mut. *formosa* E gives matroclinic progeny. Reciprocal cross mut. *formosa* E \times strain C gives F₁ of f. *typica* (flat-leaved) plants, and Mendelian segregation in F₂ of 3 f. *typica*: 1 mut. *formosa*.—Hypothesis of heterogametism offered in explanation of the phenomena assumes the occurrence of 2 types of gametes in *O. pratincola*, α gametes (usually female) and β gametes (usually male), the α gametes carrying some factors not represented in the β gametes. The zygote is formed by union of α gamete of pistillate parent and β gamete of staminate parent. The zygote in turn produces α (female) and β (male) gametes. In a cross the hybrid is unaffected by the nature of β of its pistillate parent, or α of its staminate parent. In addition to the characteristic α or β part, each gamete carries a group of factors common to both. At reduction, α and β behave as units; that is, there is no interchange of factors or chromosomes between characteristic α and β portions, each passing into the gametes (the α into the female, the β into the male) just as it entered the zygote from its parent. Chromosomes carrying factors common to both α and β portions of zygote show Mendelian segregation at the reduction division, each member of homologous pairs accompanying with equal frequency the α or β portions. Factors belonging to the α or β portions are inherited matroclinically or patroclinically, respectively; factors belonging to homologous and freely segregating chromosomes common to both α and β gametes are inherited in a Mendelian manner.—F. *typica* E produces mut. *formosa* by a change in a factor in the α portion of the α gamete (female) having no counterpart in the β portion of the β gamete (male). The mutated α gamete of mut. *formosa* is designated α^1 ; the β gametes of f. *typica* E and mut. *formosa* are equivalent. If mut. *formosa* is the pistillate parent in cross with f. *typica* E, the hybrid receives the α^1 gamete of mut. *formosa* and is similar to mut. *formosa*; in the reciprocal cross the progeny receive the α gamete of *O. pratincola* and the progeny are all f. *typica*. Strain C differs from strain E by having, in addition to the factor for flatness in the α portion of the α gamete, a freely segregating, dominant (Mendelian) factor (*F*) for flatness present in both the α and β gametes, of which the recessive allelomorph (*f*) is carried by strain E ($\alpha\beta ff$). Mutation of the α portion of f. *typica* C ($\alpha\beta FF$) to α^1 , if it occurs, would

be masked by the presence of Mendelian factor for flatness (F) in the remaining portion of the gamete. In strain E the change is visible since the Mendelian factor is present in the recessive form (f). Strain C ($\alpha\beta FF$) \times mut. *formosa* E ($\alpha^1\beta ff$) gives flat-leaved F_1 ($\alpha\beta Ff$) in which segregation of the Mendelian factors takes place in the F_2 but is masked by the presence of a factor for flatness in the α portion of the zygote. The genotypes and the ratio in which they occur are: $1\alpha\beta FF:2\alpha\beta Ff:1\alpha\beta ff$. The plants are all flat-leaved. In the reciprocal cross the F_1 zygote ($\alpha^1\beta Ff$) is flat-leaved due to the presence of the dominant Mendelian factor F received from the staminate parent, the factor for revoluteness carried by the α^1 portion of the zygote being masked. In the F_2 a ratio of 3 flat-leaved plants ($1\alpha^1\beta FF:2\alpha^1\beta Ff$): 1 revolute-leaved plant ($\alpha^1\beta ff$) was obtained. The new f. *typica* plants occurring in the F_2 of this cross ($\alpha^1\beta FF$ and $\alpha^1\beta Ff$) are designated f. *typica* M. In 1919, Cobb and Bartlett reported [see Bot. Absts. 3, Entry 2100] that the pollen of mut. *latifolia* C was equivalent to that of its parent, f. *typica* C. The same paper recorded results of crossing mut. *formosa* within strain E and demonstrated inheritance to be matroclinic. Mut. *formosa* E \times mut. *latifolia* C gave F_1 of 209 plants, all flat-leaved; in F_2 4759 flat-leaved to 1633 revolute leaved plants were obtained, i.e., a ratio of 2.9:1. The present paper reports that mut. *formosa* E \times f. *typica* C gave F_1 of 100 plants, all flat-leaved. F_2 contained 2399 flat-leaved and 875 revolute-leaved plants; i.e., a ratio of 2.74:1. Self-pollination of f. *typica* plants from F_2 of mut. *formosa* E \times mut. *latifolia* C gave in F_3 22 non-segregating to 41 segregating progenies, approaching closely the expected 2:1 ratio. In segregating F_3 progenies the ratio of flat- to revolute-leaved plants was 3.08:1. F_4 and F_5 have shown a continuance of the Mendelian behavior of this cross. Four recessive, revolute-leaved plants from F_2 of cross mut. *formosa* with mut. *latifolia* C gave in F_3 69 plants, all revolute-leaved. Reciprocal cross, f. *typica* C \times mut. *formosa* E ($\alpha\beta FF \times \alpha^1\beta ff$) gave all flat-leaved plants in the F_1 of 782 individuals. In the F_2 , 1654 plants were grown. Segregation of the Mendelian factors for flatness (F and f) had taken place in the F_2 but was masked by the ever present α factor for flatness inherited matroclinically. Revolute character can appear only by mutation from α to α^1 in plants of constitution $\alpha\beta ff$, or $\frac{1}{4}$ the progeny. Sixteen revolute plants in F_2 , or 16 per 1000, were found.—Nine crosses mut. *formosa* E \times f. *typica* E ($\alpha^1\beta ff \times \alpha\beta ff$) gave F_1 of 305 plants, all revolute-leaved. Four F_1 plants gave F_2 of 628 plants, all revolute-leaved. Reciprocal cross f. *typica* E \times mut. *formosa* E had been shown in previous paper to be matroclinic.—Data concerning F_1 and F_2 of 18 different kinds of crosses involving f. *typica* M as one parent, and f. *typica* C, f. *typica* E, or mut. *formosa* as the other parent, confirm the author's hypothesis of non-equivalent gametes and the presence of a pair of independent Mendelian factors in *O. pratincola*. The author points out that α of strain C may mutate to α^1 but in pure strain C the mutant type will find no expression until inhibiting Mendelian factors (FF) are removed by hybridization, as happens when strain C is crossed with mut. *formosa*. In this case hybridization apparently induces mutation when as a matter of fact hybridization has only made possible the appearance of changes that occurred in the past. It is not known whether strain E arose by change in dominant Mendelian factors FF to ff , or whether the reverse took place to form strain C. It is supposed that other strains of *O. pratincola* have factors FF as none of them throws revolute-leaved mutations. The reverse mutation can take place in that mut. *nitidissima*, a type originating in the experiment garden from strain E, is a homozygous dominant for the Mendelian factors for flatness. "This paper records the case of a single unit character of the zygote, revoluteness, determined by a complicated set of phenomena: an alleomorphic pair of factors (F and f) the dominance and recessiveness of which produce no effect on the zygote except when the particular mutational change from α to α^1 has taken place; a mutation (α to α^1) occurring repeatedly, but concealed, as long as self-pollination continues, by the Mendelian factors FF , and Mendelian segregation concealed by matroclinic inheritance dependent on heterogametism (α and β gametes). It is hoped that the case may throw light upon the seemingly peculiar behavior of the *Oenotheras*."—Wilber Brotherton, Jr.

1041. CENKIN, E. G. The mechanism of evolution. Sci. Monthly 10: 496-515. 1920.—It is certain that cytoplasmic differentiations of nerve, muscle, and gland cells have no direct influence upon hereditary constitution of germ cells and very doubtful whether cytoplasmic

differentiations of germ cells themselves affect their hereditary value. While differentiations of cytoplasm of egg do control some of the most important orientations of development, there is no satisfactory evidence that these differentiations are not the result of environment, or activity of chromosomes during early stages in the formation of the egg. If it could be proved that polarity, symmetry, or localization pattern of cytoplasmic substances of the egg are carried over from generation to generation, modifications of these differentiations would be of profound influence in evolution. But if these differentiations arise anew in each egg cell, as do various differentiations of tissue cells, through interaction of nucleus, cytoplasm, and environment, then evolutionary changes in orientation may find their ultimate causes in changes in nucleus rather than in cytoplasm. In the present stage of knowledge there is not sufficient evidence to conclude that modifications of cytoplasm of germ cells are ever really inherited or are ever initial steps in evolution. Almost all experimentally produced changes in chromosomes, known to persist, occur during mitoses, while those produced during intermitoses are, with few exceptions, relatively unimportant and temporary. Furthermore, most of the persistent modifications of chromosomes thus far discovered appear during maturation stages. These modifications consist in (a) changes in chromosome number, (b) changes in chromosome constitution. Although abnormality in chromosome number is found in some mutants, it is not certain that this abnormal number is the cause of mutation and there are some good evidences that it is probably a result rather than the cause. Under changes in constitution of chromosomes are listed crossing over, duplicated genes, and deficiency. The demonstration that the amount of crossing over may be affected by temperature and other influences furnishes direct evidence that genetical constitution may be changed by environmental influences acting on the germ cells at an early stage.—Under the heading "changes in genes" the issue of "new combinations, vs. new constitution," is discussed and the author takes issue with the "dogma of immutable genes." The fact that genes are relatively complex bodies would indicate that they can not be absolutely stable and wholly uninfluenced by environment. Mutation in genes may be thought of as due to the loss or addition of certain constituent atoms or molecules or to the rearrangement of some of these. Independent recurrence of a mutation must indicate a tendency for a gene to change in a particular way, just as chemical changes tend to go in certain directions—hence "orthogenesis." Although it is certain that mutations of genes take place, and although it is highly probable that these mutations, like all chemical and physical processes, are affected by environmental conditions, it is not known what the conditions are which induce mutations or how they may be initiated or controlled.—Mutation is characterized as a response of hereditary organization to certain stimuli. Just as the nature of any response is primarily determined by the nature of the organism, while stimuli serve merely to initiate, hasten, or retard response, so the nature of a mutation is probably definitely limited by the organization of the germplasm, while extrinsic causes serve only to initiate or retard it.—Bateson's hypothesis of evolution by loss is destructively criticized.—*F. B. Sumner.*

1042. CRANE, M. B. Experiments in breeding plums with a note on peaches. *Jour. Pomol.* 2: 137-159. 4 pl., 3 fig. 1921.—Five varieties of plums were selfed and all seedlings therefrom appear self-fertile. Hairiness of bark is dominant over glabrous bark, and crenate leaf margins over serrate leaf margins. Oblate and pyriform appear to be homozygous fruit forms oval being heterozygous. Yellow-green skin color is homozygous and red and purple heterozygous. Freestone varieties yielded freestones, and clingstone varieties gave a majority of clingstone seedlings. Of 150 self-pollinated seedlings from 1 freestone variety free from spines, 1 seedling was spiny clingstone, 1 spiny freestone, and 1 clingstone spineless.—Three varieties of peaches and nectarines were tested, all self-fertile. Small and large flowers are homozygous. Eglandular leaves and leaves with reniform glands are homozygous. Eglandular leaves are more susceptible to mildew. Six seedlings from a purple leaved variety had purple leaves.—*C. H. Connors.*

1043. CZUBER, E. Zu Paul Ehrenbergs Beweiss für die Anwendbarkeit der Wahrscheinlichkeitsrechnung auf Feldversuche. [Paul Ehrenberg's proof for the applicability of bio-

metrical method in field studies.] Landw. Versuchssta. 98: 223-241. 1921.—According to Czuber the formulae for the calculation of the standard deviation and probable error (S. D. = $\sqrt{\frac{\sum D^2}{n-1}}$, P. E. of a single determination = $.6745 \times \text{S. D.}$) can only correctly be applied when, the results give a frequency polygon which closely approaches the normal curve. The frequency distributions for various sets of data obtained from field studies are given. Many of the frequency distributions are distinctly asymmetrical and the calculated mean does not always coincide with the largest frequency class. For these reasons Czuber disagrees with the conclusion reached by Ehrenberg, that probable errors, obtained by the method outlined, can be legitimately applied to the data obtained from field experiments.—H. K. Hayes.

1044. DETLEFSEN, J. A. [Rev. of: WALTER, H. E. *Genetics, an introduction to the study of heredity*. Rev. ed., xvi + 354 p., 92 fig. Macmillan & Co.: New York, 1922.] Science 56: 145-146. 1922.—Great progress in genetics since previous issuance of this text has necessitated many changes. One of the new chapters on Architecture of the Germ Plasm gives most important advances made recently in genetics. The reviewer warns that conclusions as to distance between genes have outstripped evidence. A chapter on determination of sex introduces much new material. In this new edition the chapter on Pure Lines and Selection and the presentation of cytological facts follow Mendelism. Some criticism on mathematical aspects is made. New diagrams and the readable style of the book are praised by the reviewer.—J. P. Kelly.

1045. DUJARDIN, F. Pollination of tree fruits. Rev. Hort. 93: 300-302. 1921.—All varieties tested of sweet and sour cherries, except a few sweet, are self-sterile.—No cases of cross-sterility were found among apples. Some cases of cross-sterility were found among plums. Cross-sterility in cherries is questioned.—Varieties of *Prunus institia* probably are the best pollinators for varieties of *Prunus domestica*. *P. spinosa* failed.—C. H. Connors.

1046. EDLER. Pflanzenzüchtung und Sortenwahl. [Plant breeding and the selection of varieties.] Arbeit. Deutsch. Landw. Ges. 314. 25-42. 1921.—A brief general review is presented of work done in Germany on selection of field crops, and the machinery set up by the Deutsche Landwirtschaftliche Gesellschaft for testing out of varieties.—A. J. Pieters.

1047. GAUGER, MARTIN. Die Mendelschen Zahlenreihen bei Monohybriden im Lichte der Dispersionstheorie. [The Mendelian ratios in monohybrids in the light of the dispersion theory.] 54 p. Diss. Göttingen. 1919.—Published also in Zeitschr. Indukt. Abstamm. u. Vererb. 22: 145-198. 1920 [see Bot. Absts. 6, Entry 1675].

1048. GRIFFEE, FRED. First generation corn varietal crosses. Jour. Amer. Soc. Agron. 14: 18-27. 1922.—Previous investigations are summarized to show that, out of a total of 146 corn varietal crosses, 113 exceeded the parental average in yield of grain and 84 excelled the better yielding parent. Increase for all crosses was 11.7 per cent over average of parents. New results at Minnesota show that crossing gives greater increases when the parental varieties are closely selected for ear type than when selected on the basis of yield alone. A combination of flint maize (Squaw Flint) and dent (Minnesota No. 13) was found to be desirable in yield and early maturity.—D. F. Jones.

1049. HAGEDOORN, C., EN A. L. [HAGEDOORN]. Cucurbita-Strijdvragen. [Disputed questions in Cucurbita.] Genetica 4: 64-69. 1922.—The authors believe that they have succeeded in producing parthenogenetic seed in hybrid plants of *Cucurbita* because (1) closed buds on non-hybrid plants produced no seed; (2) closed buds on hybrid plants produced either fruits full of good seed or no seed at all, but never a few good seed only; (3) the segregation in progenies raised from such seed in hybrid plants are always what might be expected to result from the cross which was made. [See also Bot. Absts. 12, Entry 1055].—E. W. Sinnott.

1050. HYDE, ROSCOE R. An eyeless mutant in *Drosophila hydei*. *Genetics* 7: 319-334. 1922.—A recessive eyeless mutant gave discordant results from crosses and inbred cultures until it was learned that warm and dry conditions of the culture were necessary for its full expression. Warm moist cultures produced few eyeless, while cool dry cultures produced some mutants. Pure cultures of eyeless appeared when cultures were kept warm and dry. The influence of temperature and moisture is exerted after the eggs are laid. Back-crosses of hybrids to a double recessive eyeless-scarlet race showed linkage between these 2 mutant genes and no crossing over in the male.—J. L. Collins.

1051. JORDAN, DAVID STARR. The California poppy. *Science* 56: 168-169. 1922.—The author calls attention to a marked variation of *Eschscholzia californica* and its suitability for genetical work.—J. P. Kelly.

1052. KOTTUR, G. L., and R. K. KULKARNI. Cross-fertilization in Jowar (*Andropogon sorghum*). *Agric. Jour. India* 17: 413-416. *Pl.* 25. 1922.—The article records briefly the results of the authors' observations on the frequency of natural cross-fertilization in a field of sorghum surrounded by several rows of another variety. The variety in the field was a compact-panicked form in which the percentage of cross-fertilization is usually low as compared with that in the loose-panicked varieties. From 32 selected heads 7,616 plants were grown and of these 303, or approximately 4 per cent, were found to be hybrids. It could not be definitely said that all the intermediate forms classed as hybrids arose from cross-pollination in that season because the variety in the field was not a pure line. Only 2 out of the 32 heads selected were entirely free from cross-pollinated grains.—H. N. Vinall.

1053. KREMERS, R. E. The volatile oil of *Mentha aquatica* Linne, and a note on the occurrence of pulegone. *Jour. Biol. Chem.* 52: 439-443. 1922.—*Mentha aquatica* is now regarded as one of the parents of peppermint (*Mentha piperita*), and the elaboration of its oil can be thought of as following the same course as that of the other parent (spearmint, *Mentha spicata*) but stopping with the esterification of linalool.—G. B. Rigg.

1054. KRISTOFFERSON, KARL B. Studies on Mendelian factors in *Aquilegia vulgaris*. *Hereditas* 3: 178-190. 1922.—One plant of *Aquilegia vulgaris* bearing self-colored, dark blue flowers yielded a family of 40 offspring of which 22 were dark blue, 9 reddish violet, 7 light blue and 2 white. This ratio and results from subsequent generation led to the following digenic hypothesis: factor *B* conditions light-blueness; factor *R*, reddish color; *B* and *R*, present together, give deep blue; both absent leads to white. Other experiments revealed a simple recessive factor causing white margins of colored corollas. The factor *R* is thought to be "pleiotropic," i.e., to have effects on a plant other than that of producing reddish flower color; but the author admits the possibility of linkage explaining this situation.—J. P. Kelly.

1055. LOTSY, J. P. Cucurbita-Strijdvragen. [Disputed questions in Cucurbita.] *Genetica* 4: 70. 1922.—In this answer to Hagedoorn [see Bot. Absts. 12 Entry 1049] the author refuses to accept the existence of parthenogenesis in *Cucurbita* until it has been shown that the plants in question are haploid in chromosome number.—E. W. Sinnott.

1056. LOTSY, J. P. Eenige resultaten van het *Oenothera*-jaar 1920. [Some results of the *Oenothera* year 1920.] *Genetica* 2: 481-528. 57 fig. 1920.—I. The common origin of the *linearis* forms. The author states that *O. linearis* appeared in cultures from (1) a selfed *O. biennivelutina*; (2) a cross between *O. murivelutina* and *O. biennivelutina*; and (3) a selfed *O. fallax*, which was obtained from the reciprocal cross (*O. biennis* × *O. Lamarckiana*) of the one from which the aforementioned *O. biennivelutina* forms (*O. Lamarckiana* × *O. biennis*) came. The plants of *O. Lamarckiana* used in these crosses were from the same parent, and those of *O. biennis* were collected on the same spot. From a cross between another *O. biennis* plant collected at the same place and *O. muricata* the author obtained a *linearis* form, which he called *O.*

linearis stellaris (regular star-shaped rosette). He believes the following to be the only possible conclusion: "*O. biennis* from the railroad at Almen had hidden within all factors which were necessary to influence the formation of *linearis* forms." This does not mean according to the author that these *linearis* forms are identical, but that they have in common, one or more factors which cause the narrow leaves.—II. The common origin of the *epilobioides* forms. A case similar to that in I was observed in *O. epilobioides*, a form which appeared 3 times: (1) in 1918 in a cross between *O. murivelutina* and *O. muricata*; (2) in 1919 in a cross between *O. murilaeta gigas* and *O. murivelutina*; (3) in 1920 in a culture of a selfed variegated branch of a sectorial-variegated *O. biennivelutina*. These 3 forms are not alike in every respect, only in general habit and growth. The author believes that the *epilobioides* character is due to *O. murivelutina*, which appears in the ancestry of all 3 forms.—III. The common origin of the variegated forms. These forms were: (1) *O. biennilaeta*, sectorial variegated; (2) *O. biennivelutina*, sectorial variegated; (3) *O. biennilaeta*, aureo-variegated, and several variegated forms in other cultures. In every case *O. biennis* gathered at Almen was among the ancestors of the variegated forms. The author says "that neither the *linearis* forms, nor the variegated forms were mutants from the cultures in which they appeared," but that the factors influencing their specific character were already present in the *O. biennis* group from Almen.—IV. The common origin of the new *sulfurea* form. These forms were *O. biennivelutina sulfurea* and *O. fallax sulfurea*, and, as the author shows, due to an *O. biennis* ancestral influence similar to that in the forms mentioned in I and III. This association of factors influencing variegation and factors influencing yellow-flower color brings the author to suppose the possibility of the existence of Mendelizing factors, among which "white" and "sulphurea" should be extreme recessive factors for "green" and "yellow."—V. Different grades of green. The following results were obtained: The F_1 of the cross *O. Lamarckiana* \times *O. muricata* consisted of 60 *O. gracilis*, 64 *O. gracilis diluta*, and 72 white individuals; among a similar F_1 were 80 *O. gracilis diluta* and 85 white individuals. Among the F_1 of the cross *O. murivelutina* \times *O. biennilaeta* were some intermediate large-flowered forms, *O. mulamarckiana*, and this crossed with *O. muricata* gave rise to 71 *O. gracilis*, 95 *O. gracilis diluta*, 57 *O. coerulea*, and 86 *O. coerulea diluta* individuals, among all of which great differences in chlorophyll content were noticed. This condition resulted in the loss of new forms lacking chlorophyll, e.g., *O. rubrosepala* (new form from a selfed *O. biennivelutina* culture) kept alive during the winter in a greenhouse.—VI. Intermediate forms. The author discusses *O. submulamarckiana*, a cross between *O. mulamarckiana* and *O. murivelutina*. Other intermediate forms are: (1) a *laeta-fallax* form from a selfed *O. fallax*, a cross between *O. Lamarckiana* and *O. fallax*; *O. fallax sulfurea*, from a selfed *O. subfalloides*; and *O. biennilaeta cauli-punctata*, like *O. biennilaeta* but with the red stem dots of *O. biennivelutina*.—VII. Multiformity of descendancy was observed in several cases. A. *O. laevifolia* (from cross *O. fallax* \times *O. Lamarckiana*) gave, when selfed, 3 *O. nanella*, 1 *O. falloides*, 31 *O. Lamarckiana*, 3 *O. laevifolia*, and 1 questionable *O. Lamarckiana*. B. Division according to flower size among *O. murivelutina* and *O. murilaeta*. In 1918, the author noticed 3 flower sizes, large, medium, and small. He selected plants, and progenies came true to form. Among the individuals of a selfed *O. murilaeta* with round buds were 9 round buds (petals broader than long) to 3 pointed buds (petals longer than broad), showing pointed buds to be recessive. C. Formation of *O. Heriberti*, formerly *O. murilaeta-coerulea*. The author claims that "*O. muricata* forms others besides 'rigens' and 'curvans' egg cells, the chromosome complex of which consists of a mixture of 'rigens' and one or more 'curvans' chromosomes. The combination of such a mixed *muricata* egg cell with a 'gaudens' gamete forms *O. Heriberti*, which by selfing in our culture gave 28 *murilaetas* (16 round buds and 11 pointed buds, 1 died) and reproduced itself only once." Other examples of multiplicity of hybrids reported by the author are: (1) The F_1 of *O. biennilaeta gigas* \times *O. biennivelutina* gave 8 different types of plants, namely, *O. Lamarckiana proxima*, one which did not come into flower, *O. bullata*, *O. albiva*, *O. chloriva*, *O. flavosepala*, *O. semilata*, and *O. violaceo-sepala*. (2) The F_1 of *O. murilaeta gigas* \times *O. murivelutina* gave 3 types of plants, namely, *O. plicata*, *O. parvifolia*, and *O. laciniata*. The theoretical discussion of all these data will be given in a following paper.—Peter J. Klaphaak.

1057. LOTSY, J. P. *Oenothera*-proeven in 1919. [*Oenothera* experiments in 1919.] *Genetica* 2: 385-399. 1 pl., 3 fig. 1920.—To investigate the question whether it is possible to find among *Oenotheras* any influence of the protoplasm on the morphological characteristics of the different forms, the author used *O. Lamarckiana* forms obtained by crossing. One group of cultures came from a self-pollinated individual of an *O. Lamarckiana* culture, originated by crossing *O. biennilaeta* (from a cross of *O. biennis* \times *O. Lamarckiana*) with *O. murivelutina* (from a cross of *O. muricata* \times *O. Lamarckiana*). This group of cultures had, according to the author, a "gaudens-velans" combination in "albicansplasma." The latter was derived from the maternal ancestor *O. biennis*. Another group of cultures came from a self pollinated individual of an *O. Lamarckiana* culture obtained by crossing *O. murilaeta* (from a cross of *O. muricata* \times *O. Lamarckiana*) with *O. fallax* (from a cross of *O. Lamarckiana* \times *O. biennis*). The *O. murilaeta* used in this cross came from the same culture as *O. murivelutina* in the former cross. The *O. Lamarckiana* obtained had, then, a "gaudens-velans" combination in "rigensplasma," this being derived from the maternal ancestor *O. muricata*.—While the flowers of the 1st group are large, those of the 2nd are small. Both were typical *Lamarckianas*, which could not be differentiated until in flower. Cultures from self-pollinated individuals of the above-named groups were exactly like their parent.—A comparison of other groups of *O. Lamarckiana* with either "albicans" or "rigens" plasma showed that *Lamarckianas* with "rigens" plasma are small-flowered and never have large flowers, while those with "albicans" plasma are large-flowered. Among the latter are, however, a few heterogeneous forms which have some small-flowered plants, for instance No. 142 *O. Lamarckiana* coming from *O. biennilaeta* (*pseudo-gigas*) \times *biennivelutina*. It has 25 small-flowered to 17 large-flowered plants. The author concludes for the present that "the rigensplasma depresses the flower size of the velans-gaudens combination." He does not claim that this change in flower size is hereditary and plans to discuss, as soon as the results for 1920 are tabulated, whether or not a change in the velans-gaudens complex may possibly have taken place and, if so, its importance on his provisional conclusion in regard to the influence of protoplasm.—*Peter J. Klappaak*.

1058. MAINWARING, C. Improvement of Rhodesian white maize by selection. *Rhodesia Agric. Jour.* 19: 291-294. 1 fig. 1922.—Only white maize is grown in Rhodesia as it is neither profitable nor desirable to export mixed grades; but, though practically the only 2 acknowledged varieties grown are Hickory King and Salisbury White, the plants are far from uniform in vigor, etc. In order to produce uniformity, careful selection is necessary. The methods of selection are ear-to-row test, mass selection, and field selection. In the selection of ears for seed careful attention should be given to the following points: trueness to type, uniformity of appearance, size, shape of the ears and character of the indentation of the grain; the ears should be heavy when dry. A description is given of Salisbury White maize and Hickory King.—*L. J. Goldblatt*.

1059. MENDIOLA, N. B. A study of the inheritance of beardedness in rice in natural hybrids. *Philippine Agric. Rev.* 15: 28-43. 1 pl. 1922.—A study of 3 generations shows that beardedness in the 2 varieties studied is partly dominant over beardlessness. Line selection only can be recommended as the best method of purification.—*E. D. Merrill*.

1060. MEUNISSIER, A. Observations sur l'hérédité du caractère "pois à trois cosses" et du caractère "pois chenille." [Observations on the inheritance of the character "3-podded peas" and the character "chenille."] *Genetica* 4: 279-320. 1922.—Peas having 3 flowers per peduncle were crossed with a variety having the normal number (2). The 3-podded character is a recessive of great variability. The adherence of the peas to each other in the pod is called "chenille" (caterpillar), a highly variable, recessive character which is always associated with emerald foliage. In general, pink-flowered plants are less strongly "chenille" than white- or purple-flowered plants. From the results obtained it is impossible clearly to distinguish the modifying effects of environment from the effects produced by the action of genetic factors.—*Hugh C. McPhee*.

1061. PAINTER, THEOPHILUS S. **The sex chromosomes of the monkey.** *Science* 56: 286-287. 1922.—Cytological studies show that there are 27 pairs of chromosomes in the "ring-tail" monkey. The sex complex consists of relatively large X- and minute Y-chromosomes. X- and Y-chromosomes separate in the 1st maturation division and divide equationally in the 2nd. Figures are presented of the sex-chromosome complex in dividing spermatogonia, behavior of X- and Y-chromosomes in 1st spermatocyte division, and XY complexes in opossum, monkey, and man.—*R. E. Clausen.*

1062. PRIDHAM, J. T. "Flour strength" and "protein content." *Agric. Gaz. New South Wales* 33: 630. 1922.—High protein content is not necessarily associated with excellency of gluten in flour. If a movement toward entire wheat bread should assume importance, strength of flour, as well as yield of grain, must receive serious consideration by the plant breeder. *L. R. Waldron.*

1063. SCHAFFNER, J. H. **The sexual nature of vegetative or dichotomous twins of *Arisaema*.** *Ohio Jour. Sci.* 22: 149-154. 1922.—Dichotomous twins of *Arisaema triphyllum* (L.) Torr. and *A. Dracontium* (L.) Schott. showed fluctuations in some cases but were remarkably alike in varietal characters and were always of the same sex. Though no experiment whereby twins were induced to develop different sexual states was made, the fact that the sexual state of *Arisaema* has been changed by proper treatment is considered evidence that identity of sex in duplicate twins cannot be regarded as conclusive proof that sex is determined by Mendelian factors.—*H. D. Hooker, Jr.*

1064. SOUTHWORTH, W. **Alfalfa hybridization.** *Sci. Agric.* 2: 257-264. 1922.—The various parts of the alfalfa flower are described and illustrated. A careful study of the tripping of the flowers indicates that the spring-like-force which causes tripping is exerted by the staminal column rather than the pistil. Two ways of emasculating the flowers and various means of protecting the flowers after the pollen has been applied to the stigma are described. A greater percentage of fertile crosses were obtained during moderately warm dry weather. Treatment for a short time with sulphuric acid hastened germination when the hybrid seed contained considerable hard seed.—*H. L. Westover.*

1065. SUMNER, F. B. **Linkage in *Peromyscus*.** *Amer. Nat.* 56: 412-417. 1922.—The linkage relations between the genes for red-eyed yellow, pink-eyed yellow, and albinism in rats and pink eye and albinism in the mouse are stated, together with some data on linkage between the genes in *Peromyscus* for albinism and a pale red-eyed mutant, "pallid." Tests were made with F₂ extracted albinos and pallids mated with albino and pallid mice of known genotype. Among 135 young from 18 mice only 2 albinos and no pallids appeared, in the absence of linkage 37 albinos and 18 pallids should have been expected. The gene for pallid in *Peromyscus* and the gene for red-eyed yellow in Castle's rats are considered homologous. Albinos mated to a race of yellows gave no evidence of linkage.—*J. L. Collins.*

1066. VENKATRAMAN, T. S. **Germination and preservation of sugar-cane pollen.** *Agric. Jour. India* 17: 127-132. 1 pl. 1922.—The author points out that the iodine test for pollen viability simply reveals grains that were once viable. Germination tests are needed to determine viability at the time of pollination. The author was successful in using live stigmas of *Datura fastuosa* for germinating cane pollen. In sugar-cane, pollen begins to lose its viability in 20 minutes in the open air. Pollination must be effected promptly after pollen collection. A method is described by which pollen is kept alive for 11 days.—*J. P. Kelly.*

1067. WEINSTEIN, ALEXANDER. **Crossing over, non-disjunction, and mutation in *Drosophila virilis*.** *Sigma Xi Quart.* 10: 45-53. 1922.—This preliminary report shows the parallelism between *D. melanogaster* and *D. virilis* for crossing over, coincidence, non-disjunction, and the appearance of the same type of gynandromorphs and mutations. The rate of secondary non-disjunction was found to be lower than in other species. The YO male is sterile as in

D. melanogaster, the XXY females somatically indistinguishable from XX females. Triple cross-over is more frequent in the longer *D. virilis* X chromosome than in *D. melanogaster*. Two quadruple crossovers are reported for the X chromosome. Five mutant characters are mentioned, some of which resemble mutations in *D. melanogaster*. Several mutations appearing in *D. melanogaster* are briefly described.—*J. L. Collins*.

1068. WITSCHI, EMIL. Vererbung und Zytologie des Geschlechts nach Untersuchungen an Fröschen. [Inheritance and cytology of sex according to investigations on frogs.] Zeitschr. Indukt. Abstamm.- u. Vererb. 29: 31-68. 1 pl., 8 fig. 1922.—From temperature experiments and the F₁ generation of crosses made between "differentiated" races (i.e., races whose tadpole gonads differentiate directly into pure males and females) and "undifferentiated" races (i.e., races whose male tadpole gonads are believed by the author to develop as transformations of female gonads) the following conclusions are drawn. (1) That the male of the differentiated race is heterozygous, with the formula *FFMm*; (2) that both male and female of the undifferentiated race are homozygous for sex, with the formula *FFMM*; (3) that the factors *F* and *M* in the undifferentiated race are equipotent, the sex being finally determined by thermal and resulting nutritive conditions; (4) the potencies of the factors *F* and *M* are different in each of the 4 differentiated races.—The author studied spermatogenesis of *Rana temporaria* and reports a diploid number of 26 chromosomes for this species as contrasted with reports by previous authors of 24 for other European species. He was unable to distinguish any X or Y chromosomes.—*C. L. Parmenter*.

HORTICULTURE

(See also in this issue Entries 1022, 1029, 1037, 1042, 1116, 1175, 1355, 1362, 1366, 1420, 1451, 1461, 1475, 1477, 1489, 1497)

FRUITS AND GENERAL HORTICULTURE

1069. ANONYMOUS. Coconut investigation. Agric. Bull. Federated Malay States 9: 175. 1922.—There appears to be no definite relationship between the diameter or circumference of coconuts and their copra content, nor between the volume of the nut and the volume of the kernel. The percentage of oil present appears to reach a maximum when the embryo weighs from 80 to 100 gm.—*I. H. Burkill*.

1070. ANONYMOUS. Export of grapes. Results of experimental shipments. Jour. Dept. Agric. Union South Africa 5: 231-233. 1922.—This article gives a report of the Trade Commissioner and lists the prices obtained in London for 27 varieties of grapes grown at the Paarl Viticultural Experimental Station last season. It was the purpose of the test to determine suitability for market. The views of the Government Viticulturist are given for each variety.—*L. Goldblatt*.

1071. ALLEN, W. J., and W. LE GAY BRERETON. Packing house appointments. Agric. Gaz. New South Wales 33: 515-523. 6 fig. 1922.—Methods are designed for apple packing under Australian conditions.—*L. R. Waldron*.

1072. ARNOLD, W. S. The curing of the lemon. Agric. Gaz. New South Wales 33: 579-584. 1922.—The conditions and methods discussed apply particularly to the Kurrajong citrus district.—*L. R. Waldron*.

1073. BARTLETT, R. G. Ripening bananas in an air-tight chamber. Agric. Gaz. New South Wales 33: 482. 1922.—A temperature of from 75 to 80°F. ripens the fruit in from 6 to 48 hours.—*L. R. Waldron*.

1074. BLACK, O. F., and J. W. KELLY. Examination of the fruit of *Samuela carnerosana* Trelease. Amer. Jour. Pharm. 94: 477-479. 1922.—The fruit has a high percentage of soluble sugars (62.2 per cent of reducing sugars, calculated as dextrose, and 3.80 per cent of non-reducing sugars, calculated as sucrose) which might make it valuable for the manufacture of alcohol. The authors state that 1 ton of dried fruits would yield theoretically 500 pounds of alcohol. The fruits, though without taste, might, because of high pectic content, be used for jams and jellies with other fruits lacking in pectic material. Tests for alkaloids were negative. Ether removed from the dried seed about 20 per cent of a yellow oil with a small amount of lecithin. Chloroform removed a wax-like product which did not seem to possess promising properties for further investigation.—Anton Hogstad, Jr.

1075. CRAWFORD, D. C., and N. A. SHAW. Fertilizers for fruit trees in the Western Province. Jour. Dept. Agric. Union. South Africa 4: 514-520. 1922.—The 3 elements of plant food that promote healthy growth are nitrogen, phosphoric acid, and potash; lime and gypsum exert a beneficial effect on the physical and biological condition of the soil. The source and method of application of these fertilizers are described, and amounts are recommended for securing a paying crop.—L. Goldblatt.

1076. DAVIS, R. A. Export of citrus fruits. Union South Africa Dept. Agric. Bull. 1922³: 19 p., 8 fig. 1922.—This is a revised edition of the Bulletin, Local Series No. 55 of 1918. The proper method of picking and packing fruit for export is described, the types of fruit most suitable for this purpose discussed, and extracts are given from the fruit export act.—E. M. Doidge.

1077. HELMER, R. H. The practical use of fertilizers. Ann. Rept. British Columbia Fruit Growers Assoc. 32: 37-38. 1921.—Nitrogen is the chief element lacking in semi-arid orchard soils and, in most cases, can probably be best supplied by the growing of leguminous cover crops.—J. W. Eastham.

1078. HUNTER, W. T. Building up our orchard soils. Agric. Jour. [British Columbia] 7: 58-59. 2 fig. 1922.

1079. MILSUM, J. N. The African oil-palm in Sumatra. Agric. Bull. Federated Malay States 9: 90-104. 1921.—An account is given of the cultivation of *Elaeis guineensis*, its aided pollination, yield, and pests.—I. H. Burkill.

1080. PHILLIPS, E. P. A potential weed *Araujia sericifera* Brot. Jour. Dept. Agric. Union South Africa 5: 151-152. 1922.—An account is given of this creeper which is spread all over the Union and is a nuisance in some gardens.—L. Goldblatt.

1081. POLE EVANS, I. B. Report on cold storage conditions for export fruit at Capetown. Union South Africa Dept. Agric. Bull. 1920²: 9 p., 6 fig. 1920. The decay of fruit cannot be attributed to unsatisfactory conditions in the railway trucks or the Government cold stores at the docks. The cool chambers on the ship and those belonging to the Imperial Cold Storage Company were not in a satisfactory state with regard to contamination with mould spores.—E. M. Doidge.

1082. TERRY, H. P. Pruning of deciduous trees. Union South Africa Dept. 1921⁵: 34 p., 27 fig. 1921.

1083. THOMSON, MARY R. H., V. A. PUTTERILL, and GEORGE HOBSON. Investigations on export citrus fruit from South Africa during 1921. Union South Africa Dept. Agric. Bull. 1922¹: 69 p., 43 fig. 1922.—Care in handling is again emphasized. On the boat the fruit should be kept at a temperature of 43-50°F.; however, air circulation and ventilation are as important as temperature. The quality of wrappers used on South African fruit is poor; this is one of

the causes of the unattractive appearance of certain packs. Waxed wrappers have been used experimentally with marked success. Oranges from certain districts, *e.g.*, Clanwilliam, do not appear to have good export qualities.—*E. M. Doidge*.

1084. TURNER, A. G. Citrus fruit growing in Rhodesia. Rhodesia Agric. Jour. 19: 159-168. Pl. 1-2, fig. 1-3. 1922.—The citrus industry in Rhodesia is reviewed, and the following items are discussed: selection of site, varieties to plant, and planting operations. The most suitable varieties for export trade are: (1) Washington Navel, (2) Valencia Late, (3) Jaffa, (4) Joppa, (5) Mediterranean Sweet, and (6) Paper Rind St. Michael. The first 2 are prime favorites at present. The 2 methods of planting are the square system and the hexagonal system.—*L. J. Goldblatt*.

1085. TURNER, A. G. Citrus fruit growing in Rhodesia. Rhodesia Agric. Jour. 19: 301-312. Pl. 1-5, fig. 1-7. 1922.—The following phases of citrus culture are dealt with: irrigation, fertilization, pruning, and spraying. No citrus orchard should be laid out in Rhodesia without the presence of facilities for irrigation. The 2 best methods of irrigating are by furrows and by a modified form of checks.—*L. J. Goldblatt*.

1086. WARCOLLIER, ET LE MOAL. Disparition progressive de l'acide sulfureux libre dans un jus de pomme conservé. [The progressive disappearance of free sulphuric acid from the juice of preserved apples.] Compt. Rend. Acad. Sci. Paris 174: 634-637. 1922.

1087. WESTER, P. J. A list of the tropical fruits at the Lamao Experiment Station. Philippine Agric. Rev. 13: 358-362. 1921.—This is a list of nearly 200 species, arranged alphabetically under the Latin names with accepted local names. No data of any kind are given regarding any of the species.—*E. D. Merrill*.

1088. WESTER, P. J. Notes on grafting tropical fruits. Philippine Agric. Rev. 13: 363-365. Pl. 20-25. 1921.—Random notes are given regarding the success or failure of grafting experiments in a few species of *Gnetum*, *Terminalia*, *Genipa*, *Pangium*, *Spondias*, *Eugenia*, and *Garcinia*.—*E. D. Merrill*.

1089. WESTER, P. J. Seedless breadfruits in the Caroline Islands. Philippine Agric. Rev. 14: 201-204. 1921.—This is merely a list of the native names with some very brief data regarding the types of fruits taken from Christian's book published in 1899 entitled The Caroline Islands.—*E. D. Merrill*.

1090. WESTER, P. J. The avocado and its propagation. Philippine Agric. Rev. 14: 185-194. Pl. 9-11. 1921.—Methods of propagating this popular fruit are discussed in a general way.—*E. D. Merrill*.

1091. WESTER, P. J. The food plants of the Philippines. Philippine Agric. Rev. 14: 211-384. Pl. 2-35, map. 1921.—A popular description is given of native and introduced species wild and cultivated, that are of value or potential value as food plants. The species are arranged alphabetically under their local names, with the addition of corresponding scientific names.—*E. D. Merrill*.

FLORICULTURE AND ORNAMENTAL HORTICULTURE

1092. ANONYMOUS. Native plants at the National Botanic Gardens. No. 13. *Listrostachys arcuata*. No. 14. Silver trees. South African Gard. 12: 249. 1 fig. 1922.—A brief description is given of each of the plants mentioned.—*E. M. Doidge*.

1093. BENEDICT, R. C. The Boston fern show. Amer. Fern. Jour. 11: 97-105. 1921. [1922].—The author describes the fern show held in Horticultural Hall, Boston, Sept., 1921. A list of the 248 forms shown is given; out of the 150 fern genera known, 54 were represented.—*F. C. Anderson*.

1094. DAY, W. B. The botany of aloes. Jour. Amer. Pharm. Assoc. 11: 620-621. 1922.—The cultivation, production, and synonymy of the various species of aloes is briefly discussed.—*Anton Hogstad, Jr.*

1095. MATHEWS, J. W. The cultivation of Geraniaceae. Jour. Bot. Soc. South Africa 8: 8-9. 1922.—Their requirements under cultivation vary as largely as their form. The native species are readily raised from seed. The perennial *Monsonia* and shrubby *Pelargoniums* may be increased from root-cuttings.—*E. P. Phillips.*

1096. MATHEWS, J. W. The cultivation of heaths. Jour. Bot. Soc. South Africa 8: 21. 1922.—Given good seeds, heaths are readily raised and quickly reach the flowering stage, most sorts doing so in their 3rd year. A compost made up of equal parts of sand, leaf-mould, peat, and loam suits the hillside species, and one of equal parts of sand, leaf-mould, and peat will suit the moisture-loving ones.—*E. P. Phillips.*

1097. MESSEL, L. A garden flora. Trees and flowers grown in the gardens at Nymans. County Life: London, 1918.

1098. PALMER, R. M. Gladiolus culture. Agric. Jour. [British Columbia] 7: 181-182. 1922.—The article deals in a popular manner with the growing of this plant on southern Vancouver Island.—*J. W. Eastham.*

VEGETABLE CULTURE

1099. ANONYMOUS. Trinidad dasheen. (*Colocasia exulenta*) [esculenta]. Agric. Gaz. New South Wales 33: 548. 1922.—Trials of this plant at Wollongbar and Grafton have proved failures.—*L. R. Waldron.*

1100. BECKEL. Anbauversuche mit Spätwirsingkohl. [Cultural experiments with late Savoy cabbage.] Mitteil. Deutsch. Landw. Ges. 37: 509-512. 1922.—A report is made on tests carried out in 1917, 1918, 1919, 1920, and 1921 at 9 stations and with 4 varieties.—*A. J. Pieters.*

1101. KERLE, W. D. Sweetpotatoes. Experiments with varieties from the United States. Agric. Gaz. New South Wales 33: 495-496. 1922.—The imported varieties did well under adverse conditions, and their superior flavor and cooking qualities make them a valuable addition.—*L. R. Waldron.*

1102. KUHN, K. Von jüngsten Stand der Gemüse—und Beerenobstgärtnerel in Petersburg und Umgegend. [Condition of vegetable and berry raising in Petrograd and vicinity.] Gartenwelt 26: 351. 1922.—In Russia nurseries are in bad condition and can be built up only by foreign help. Vegetable growing has revived somewhat, but production is far less than before the revolution. The growing period is but 3 months, though the days are long. Only the early varieties of vegetables are grown, the following being standard. (1) Cabbage; Glückstädter, Ruhm von Enkhuizen, Braunschweiger, and a very early one originally from southern Russia, Nummer I; (2) turnips; Krasnoselskoje is the best; (3) cucumbers; Muromsche, Wjasnikowsche, and Borowsche.—Seed selection is very faulty as private trading is forbidden, and agents knowing nothing of vegetable seeds buy large quantities abroad.—Fruit trees do not thrive with the exception of the following varieties of apples, which do not always ripen; Antonowka, Weisser Klarapfel, and Lehm. No pears, plums, or cherries can be grown on account of the winter, but the following berries are produced; strawberries, Lexton Noble and Deutsche Evern; gooseberries, Avenarius; raspberries, Usanka. Berry growing was once profitable, but many large berry plantations are now either in bad condition or entirely ruined.—*J. C. Th. Uphof.*

1103. MARTIN-CLAUDE. *Les champignons sèches sur le marché de Paris.* [Dried mushrooms in the Paris market.] Bull. Trimest. Soc. Mycol. France 37: 148-149. 1921.—Drying is done in ovens heated by radiators. Tests showed that when placed in water specimens absorb water to the extent of 2.43 per cent of their dry weight. The flavor is not injured by drying. It is suggested that the handling necessitated by picking and drying may serve as a safeguard against the introduction of poisonous species into the market.—*D. S. Welch.*

1104. REICHELT. *Ergebnis eines dreijährigen Anbauversuches mit vier Zwiebelsorten.* [Report of a three-year culture test with four varieties of onions.] Mitteil. Deutsch. Landw. Ges. 37: 524-531. 1922.—Tests made at 7 stations in 1919, 1920, and 1921 are reported.—*A. J. Pieters.*

1105. WALTERS, J. A. T. *The sweet potato.* Rhodesian Agric. Jour. 19: 411-419. 2 pl. 1922.—The culture of the sweet potato (*Ipomaea Batatas*) is described. It is the most successfully grown stock feed in Rhodesia. Besides the edible root, it provides heavy yields of palatable and succulent fodder. Planting, which should be done before mid-December, may be on the flat or on the ridge, the latter rendering the harvesting easier though not providing as heavy yields as the former.—*L. J. Goldblatt.*

MORPHOLOGY, ANATOMY AND HISTOLOGY OF VASCULAR PLANTS

E. W. SINNOTT, *Editor*

(See also in this issue Entries 1003, 1005, 1036, 1064, 1209, 1277, 1282, 1286, 1298, 1318, 1396, 1409, 1441, 1448, 1475, 1491)

1106. ARBER, AGNES. *On the nature of the blade in certain monocotyledonous leaves.* Ann. Botany 36: 329-353. 29 fig. 1922.—As a further test of the phyllode theory of the monocotyledonous leaf, the development of the leaf in many members of that class was studied and compared with that of dicotyledonous plants. It was found in some cases that the course of development was indistinguishable from that found in dicotyledons, thus furnishing no support for the theory. On the other hand, in some whole families (e.g., Palmae) and in individual genera within many different families, the blade is produced by an invagination of the petiole or sheath, a process which appears to play no part in the development of dicotyledonous leaves. Cases of invagination are so numerous and so scattered as to confirm the author's view that the blades of monocotyledons are pseudo-laminae. A classification of the leaves of the whole group is outlined, based upon the course of development and chiefly upon the numerous forms which the invagination assumes.—*W. P. Thompson.*

1107. BAAS-BECKING, L. G. M. *The origin of the vascular structure in the genus Botrychium, with notes on the general anatomy.* Recueil Trav. Bot. Néerland. 18: 333-372. 2 pl., fig. 1-48. 1921.—*Botrychium obliquum*, *B. simplex*, *B. neglectum*, *B. virginianum*, *B. silacifolium*, and *B. lanuginosum* were studied. Cauline strands, such as occur in the Marattiaceae, are absent in the stems of *Botrychium*. In *B. obliquum* the suspensor has no influence on the position of the cotyledon. The development of the vascular bundle starts at a very early stage. The protoxylem is typically irregular and the protophloem conspicuous by its shrunken cells. The junction of root and leaf traces shows that the primary xylem of the leaf becomes the innermost part of the xylem, the protophloem of the root being situated at the periphery. The pericycle is in many species of *Botrychium* the place where the secondary xylem is formed, and it is assumed that this cambial activity is an initial stage in the secondary growth of the stele. The vascular system of the root is the same as is shown by Campbell for *B. virginianum*. In *B. silacifolium* the leaf trace has a typically Osmundaceous character. The development of *B. simplex* shows a close affinity to that of *B. lunaria* and *B. neglectum*. The relationship of *Botrychium* to *Ophioglossum* and *Helminthostachys* is apparent. In the roots and prothallia, the endophytic fungus is abundant in all species, but is

absent in the leaves except in *B. silacifolium*. The mycelium stains deeply with safranin and in older stages with Bismarck brown also. The fungus closely resembles *Stygoosporium Marattiacearum*.—*J. C. Th. Uphof*.

1108. **BLOMQUIST, HUGO L.** Vascular anatomy of *Angiopteris evecta*. Bot. Gaz. 73: 181-199. Pl. 1-4, fig. 1-7. 1922.—Young sporophytes from Samoa were studied. Cortical and central vascular primary regions are distinguished. In addition to the crescentic vascular strand of the central region, commissural and medullary strands appear. The leaf traces are always given off from the same edge of the central strand, and at corresponding positions below, on the other edge, a root departs. The contribution to the leaf traces is balanced on the opposing edge by an increase in the vascular tissue and by addition of commissural strands. The spiral condition is due to the spiral succession of leaves. The course of all tissue strands and their fusions is described in detail. The evidence found leads the author to suggest "that the vascular tissue of the central region is a sympodium of leaf traces and most if not all of the central strand is of foliar origin."—*B. W. Wells*.

1109. **BOS, H.** Waterloten. [Water-sprouts.] Cultura 34: 141-151. 11 fig. 1922.—An individual of *Picea excelsa* developed a lateral twig which grew vertically and had the same appearance as the main stem. This twig did not grow from a dormant, but from an adventitious, bud. Water-sprouts are also described in *Betula alba*, *Prunus cerasus*, *Robinia pseudacacia*, and *Fagus sylvatica*.—*J. C. Th. Uphof*.

1110. **BURKILL, I. H.** Notes on Dipterocarps. No. 7. On the fruit and germination of *Isoptera borneensis*. Jour. Straits Branch Roy. Asiatic Soc. 86: 281-284. 1922.—The fruits of this species are distributed by water, the corky sepals forming the buoyant part. The embryo does not cease growth at the time of the fall of the fruit, but by pressure from within bursts the fruit-wall, usually along 3 lines. The position of these lines is not constant and is a response to the direction of the pressure.—*I. H. Burkill*.

1111. **BURKILL, I. H.** Notes on Dipterocarps. No. 8. On some large-fruited species, and in particular upon the effects of the pressure of the embryo against the interior of the fruit-wall. Jour. Straits Branch Roy. Asiatic Soc. 86: 285-291. 1922.—*Shorea Thiseltoni* King has oily fruits too large for wind distribution and which sink in water. They are distributed over small distances by rolling along the forest floor or by means of animals. The embryo does not become dormant but continues growing, bursting the fruit-wall at the places where pressure is greatest. The drying wall contracts slightly, causing one or more of these openings to gape widely. In *Vatica Ridleyana* Brandis, which has a larger and starchy fruit, and in *Dryobalanops* sp., "Koladan," which has a wingless fruit, the fruit-wall is ruptured in much the same way as in *Shorea Thiseltoni*. These are not cases of true dehiscence.—*I. H. Burkill*.

1112. **BUSCALIONI, L., E G. ROCCELLA.** Intorne ad alcune singolari anomalie delle radici di una plantula di *Amygdalus communis* L. [Some peculiar anomalies in roots of an *Amygdalus communis* seedling.] Malpighia 29: 294-315. Pl. 1-3, fig. 1-17. 1922.—A case of polytomy is reported in which the main root of a seedling was split into 4 rather short secondary roots of unequal length, brownish, and diseased in appearance. Cross sections demonstrated various distortions and abnormalities of structure, particularly in the vascular system, which are described in detail.—*Edith K. Cash*.

1113. **CATALANO, G.** Anatomia fisiologica del tessuto verde fogliare delle Graminaceae. [Physiological anatomy of the green leaf tissue of the Graminaceae.] Gior. Sci. Nat. Econ. Palermo 32: 87-119. 1921.—The author reviews in detail the work of previous writers. He suggests the following tissue classification, based primarily upon anatomical characters. Group I: Leaf tissue consisting of ordinary green cells, either elongated or isodiametric, and producing both sugar and a small amount of starch by photosynthesis. Group II: Leaf tissue consisting of cells of varying form and producing only sugar (rarely traces of starch). Group

III: Tissues of the bundle sheath forming conspicuous amounts of starch and surrounded by paler cell layers which produce no starch. The individual groups are subdivided according to the number of cell layers, the differentiation into palisade and spongy parenchyma, the relative size of the bundles, and the presence of sclerenchymatous elements and other specialized tissues. In doubtful species, the internal characters aid in assigning these species to their proper groups.—*Ernst Artschwager.*

1114. CONARD, H. S., and W. A. THOMAS. Measurements of wood fiber. *Proc. Iowa Acad. Sci.* 26: 333-335. 1919.—The maximum, minimum, and average lengths and widths are given for fibers from 41 species of wood from the genera *Pinus*, *Picea*, *Tsuga*, *Abies*, *Sequoia*, *Taxodium*, *Thuja*, *Juniperus*, *Juglans*, *Carya*, *Populus*, *Salix*, *Betula*, *Fagus*, *Quercus*, *Ulmus*, *Celtis*, *Liriodendron*, *Platanus*, *Prunus*, *Robinia*, *Acer*, *Tilia*, *Fraxinus*, and *Catalpa*. The cells were obtained by maceration with nitric acid and potassium chlorate.—*H. S. Conard.*

1115. COSTERUS, J. C. La structure de la fleur de Canna. [The structure of the flower of Canna.] *Recueil Trav. Bot. Néerland.* 17: 26-32. 1 pl. 1920.—A general account is given of the structure of the flower in this genus, with especial reference to the connective tissue ("accoupleur") which joins the style to the stamens, the syndrome of the flower, and the morphological significance of the style.—*J. C. Th. Uphof.*

1116. KONDO, M. Ueber die in der Landwirtschaft Japans gebrauchten Samen. [The seeds used in Japanese agriculture.] *Ber. Ohara Inst. Landw. Forsch.* 2: 95-131. Fig. 34-38. 1921.—This continuation of descriptions already published [see *Bot. Absts.* 5, Entry 37; 8, Entry 2013] deals with certain morphological characters of seeds and seedlings. The present article concerns the following species: *Spinacia spinosa*, *S. glabra*, *Beta vulgaris*, *Capsicum annum*, and *Nicotiana Tabacum*.—*H. S. Reed.*

1117. LUYTEN, IDA, EN MARTHA C. VERSLUYS. De Periodiciteit van de Knopontwikkeling bij *Rhododendron*, *Azalea* en *Syringa*. [The periodicity of bud development in *Rhododendron*, *Azalea*, and *Syringa*.] *Mededeel. Landbouwhoogeschool Wageningen* 22: 1-128. 9 pl. 1921.—In *Rhododendron Catawbiense* Boursault the differentiation of the flower primordia in the axils of the lower bracts in most of the inflorescences was found to be fairly advanced by June 23. Every bud contained an average of 16 flowers. By August 19 the anthers had grown very tall and the ovary had reached a fuller growth. By October 22 the flower was in the condition in which it would remain through the winter. The bractlets had now become downy and strongly toothed. During the formation of the flower the axes elongate and their later extension forms the umbel-shaped raceme. Temperature was found to have an important influence on the development of flower buds. In *Azalea mollis* × *chinensis* Anthony Koster, the terminal flower buds only were studied. The growing point forms but 1 circle of stamens (instead of 2 as in *Rhododendron*), then passing on to the formation of carpels. The few buds scales around the flower buds are almost all deformed foliage leaves and often have small leaf buds in their axils. The lateral buds have true scales. The flower bud in 1918-1919 showed no increase in size from October till April. In *Syringa vulgaris* the first floral differentiation generally occurs in the shape of a rectangular calyx wall around the primordium. The sepals arise rather irregularly from the calyx wall and the 4 petals and the stamens inside these become visible soon after. The 2 carpels appeared as small elevations in the earliest flowers on August 1, 1919. On August 18 the division into anthers was clearer, whereas the carpels were but little more developed. On September 18 differentiation into anthers and locelli was clearly visible in most flowers. The development of the inflorescence and the formation of the leaf buds are also described.—*J. C. Th. Uphof.*

1118. MANN, H. H. Variation in the flower of *Jasminum malabaricum* Wright. *Jour. Linn. Soc. Bot. London* 45: 155-158. 1920.—The variability of the corolla and calyx lobes of the tropical climber, *Jasminum malabaricum*, was studied in the jungle where the plants were unquestionably wild. Tables are presented showing counts on many flowers, and comparing

the flowers on different inflorescences and on plants differing in vigor. The flowers on various inflorescences vary irregularly. The differences in different plants are marked. Different numbers of lobes or teeth seem to be constant for different plants, and "this condition seems to be a function of the individuality of the plant." A study of the correlation in number of corolla lobes and calyx teeth was also made and a table prepared. This correlation appears to be very slight.—A. J. Eames.

1119. OBATON, F. Sur le nanism des feuilles des arbres. [Concerning nanism of the leaves of trees.] Rev. Gén. Bot. 34: 264-279. 1922.—Leaves of *Castanea vulgaris*, *Ligustrum japonicum*, *Ulmus campestris*, *Tilia* spp., *Fagus silvatica*, *Carpinus betulus*, *Buxus sempervirens*, *Prunus avium*, *Acer platanoides*, and *Celtis australis* were studied and measurements recorded. The author concludes that all the adult leaves of the same species have the same thickness. The anatomical elements have analogous dimensions and are equal in number in transverse section. Vessels which supply the same number of cells are of the same size. The grouping of the vessels into bundles is made in such a manner that comparable veins serve identical foliar surfaces; but if the number of elements to be vascularized becomes greater, the number of vessels increases, and the quantity of fibro-vascular bundles is enlarged. Thus the petiole of a small leaf of the beech presents a single group of fibro-vascular bundles where in a comparable region of the petiole of a large leaf 2 or more groups of bundles occur. In chestnut it was necessary to choose leaves having exactly the same surface in order to find in their petioles comparable structures. All the modifications observed led to the conclusion that the small leaf was not a reduction of a large leaf. All the facts showed that nanism of leaves consists entirely in the reduction of the number of elements and not in the diminution of their size.—J. C. Gilman.

1120. RECORD, SAMUEL J. On Formosan forests. [Rev. of: KANEHIRA, RYOZŌ. Anatomical characters and identification of Formosan woods with critical remarks from the climatic point of view. 317 p. Bureau of Productive Indust. Taiboku, Formosa, 1921 (see Bot. Absts. 11, Entry 443).] Geog. Rev. 12: 152-153. 1922.

1121. RINGEL-SUESSENGUTH, MARGARETE. Über Ruheorgane bei einigen Wasserpflanzen und Lebermoosen. [On resting organs in certain aquatic plants and liverworts.] Flora 115: 27-58. 1 fig. 1922.—Three aquatic plants (*Hydrocharis morsus ranae*, *Myriophyllum verticillatum*, and *Utricularia vulgaris*) and 3 liverworts (*Fegatella corsica*, *F. supradecomposita*, and *Pellia calycina*) were investigated with respect to their resting organs and the conditions necessary for their development. It was shown that the formation of these organs was not due to an autonomous periodicity but that it could be hastened or postponed by appropriate means. The most potent factors in hastening the process were found to be reduced light intensity, low temperature, and diminished supply of water and nutrient salts; while maintenance of the conditions prevailing during the summer months delayed the process or, in the case of *Pellia*, prevented it altogether. It was shown further that the resumption of growth in the resting organs could be accelerated by various stimuli, such as mechanical injury, continuous illumination, treatment with potassium cyanide, or higher temperature. Other recommended methods of forcing, however, such as treatment with ether or the injection of water or diastase, proved unavailing.—A. W. Evans.

1122. RUTKIEWICZ, M. B. Recherches anatomiques sur l'*Asarum europaeum* L. [Anatomical studies on *Asarum europaeum*.] Ann. Univ. Grenoble 33: 21-146. Pl. 1-3. 1921.—The arrested development of the 2nd foliage leaf and the atypic structure of the 1st node of the rhizome in this species is a predisposition toward the production of the ancestral form. *Asarum variegatum* of Japan has only a single foliage leaf, and it is therefore suggested that the European species is a derived type, the 2nd foliage leaf being a newly acquired, but not as yet firmly fixed, character.—Ernst Artschwager.

1123. STOUT, A. B. Cyclic manifestations of sterility in *Brassica pekinensis* and *B. chinensis*. Bot. Gaz. 73: 110-132. Fig. 1-7. 1922.—Strains of the above species charac-

terized by excessive leafy growth were studied. Three types of sterility were noted: (1) Impotence as indicated in flower abortion and arrested development of the last flowers; (2) Proliferation as exhibited by destruction of pistils through the development of floral "anlage" within the carpels at their bases. The pistils of the resultant flowers do not produce fruit; (3) Grades of sexual incompatibility are present. From complete self-incompatibility (about half the plants studied) all grades of self-compatibility ("feeble," "medium," "strong") were noted. With respect to single plants it was found that the period of mid-bloom (the climax of reproductive activity) showed the maximum self-compatibility, the period before and after being characterized by flowers which made no response to self-pollination. Work with pedigree cultures indicated that self-compatibility is a character which is not hereditary. The author points out that through the sexual differentiation of sporophytic structures in the evolution of the higher plants, "sexual reproduction has become more and more inter-related with the vegetative phase of the sporophyte and subject to its internal and biogenetic regulation. * * * * The expression of sex therefore is on the same basis as are somatic differentiations. The various types of sterility seen in these species of *Brassica* indicate a mutually limiting relationship between vegetative and reproductive vigor."—*B. W. Wells.*

1124. TONI, J. B. DE. Contribution to the teratology of the genus *Datura* L. Jour. Linn. Soc. Bot. London 47: 419-420. Pl. 25. 1921.—The author describes a type of monstrosity new to the genus *Datura*, in which monstrosities and anomalies are common. In *D. Stramonium* certain plants which form normal flowers and fruits in the early season later develop flowers with, large inflated, foliaceous calyx, and with corolla, stamens, and ovary vestigial or wanting. The writer purposes studying the inheritance of this condition.—*A. J. Eames.*

1125. VERDOORN, INEZ C. Note on *Aponogeton distachyon*. South African Jour. Nat. Hist. 3: 17-19. 1 pl. 1922.—At maturity the carpels split at the apex and the pericarp curls back and exposes the seed, which escape and float on the surface of the water. After floating for 8 days the testa splits and the "seed" sinks and germinates in the soil under water.—*E. P. Phillips.*

MORPHOLOGY AND TAXONOMY OF ALGAE

E. N. TRANSEAU, *Editor*

L. H. TIFFANY, *Assistant Editor*

(See also in this issue Entries 1257, 1328, 1427)

1126. CROW, W. B. A critical study of certain unicellular Cyanophyceae from the point of view of their evolution. New Phytol. 21: 81-102. Fig. 1. 1922.—The characters of various genera of the Chroococcaceae are analyzed with a view to ascertaining their importance in the evolution of the group and in helping to establish a satisfactory system of classification. It is concluded that "certain characters, such as the orientation of the planes of division, the form of the cell, the size of the cell, can be, to a large extent, relied upon as systematic distinctions," while the presence of pigments, pseudovacuoles, and certain types of stratified membranes may also be of importance. "The degree of differentiation of the protoplasm and particularly the distribution of the pigment are very significant." "On the other hand, the character of the stratum or colony has only slight morphological significance." The Chroococcaceae as a whole form a homogeneous group which is primitive rather than reduced in its simple characters.—*I. F. Lewis.*

1127. HAZEN, TRACY E. New British and American species of *Lobomonas*: a study in morphogenesis of motile algae. Bull. Torrey Bot. Club 49: 123-140. Pl. 5-6. 1922.—*Lobomonas pentagonia* from England and *L. rostrata* from New Jersey are described as new species; a discussion is given of morphology and reproduction. "A consideration of morphogenesis in primitive algae" gives a review of recent literature and of problems involved.—*P. A. Munz.*

1128. HAZEN, TRACY E. The phylogeny of the genus *Brachiomonas*. Bull. Torrey Bot. Club 49: 75-92. Pl. 3-4, fig. 46-50. 1922.—For the first time *Brachiomonas*, a genus of the *Chlamydomonas* group, is reported outside of western Europe. *B. submarina* Bohlin from Long Island Sound is discussed as to habits and morphology, and forma *obtusata* f. nov. is described. *B. simplex* sp. nov. is described from Norway and England. *Chlamydomonas caudata* Wille is discussed, as is the phylogeny of certain *Chlamydomonads*.—P. A. Munz.

1129. RICH, FLORENCE. A new species of *Coelastrum*. New Phytol. 20: 234-238. Fig. 1-15. 1921.—*Coelastrum schizodermaticum* sp. nov. is described from Leicestershire. The diameter of the usually 8-celled coenobium is about 35 μ , of a single cell 10-14 μ . Cap-like structures are split off from the outer walls of the cells.—I. F. Lewis.

MORPHOLOGY AND TAXONOMY OF BRYOPHYTES

ALEXANDER W. EVANS, *Editor*

(See also in this issue Entries 1121, 1214, 1253)

1130. DOUIN, CH. Sur le gamétophyte des Marchantiées. [On the gametophyte of the Marchantiaceae.] Compt. Rend. Acad. Sci. Paris 174: 121-123. 1922.—Certain cells remain alive in otherwise dead thalli for 1, 2, or even more years. These cells are the terminal initials and the secondary initials. Various anomalies are mentioned. A description of the relation of primary and secondary initials and the merophytes in the course of the development of the thallus is given.—C. H. Farr.

1131. PEARSON, W. H. New Tasmanian hepatic (*Cheilolejeunea hobartiensis* Pearson). Rev. Bryologique 49: 11-13. 14 fig. 1922.—Under this name the author describes and figures a new hepatic from the vicinity of Hobart, Tasmania, basing it on material collected by W. A. Weymouth. He likewise discusses *Strepsilejeunea austrina* Spruce of New South Wales and refers it as a synonym to *Lejeunea mimosa* Tayl.—A. W. Evans.

1132. POTIER DE LA VARDE, R. Observations sur quelques espèces du genre *Fissidens*. [Observations on certain species of the genus *Fissidens*.] Rev. Bryologique 49: 1-5. 5 fig. 1922.—The present paper is the continuation of a series, the earlier parts of which have already been abstracted [see Bot. Absts. 5, Entry 628; 6, Entry 158; 7, Entry 1975; 8, Entry 1270; 10, Entry 1844; 12, Entry 585]. The author here reports *Fissidens Curnowii* Mitt. for the first time from Tunis, the record being based on specimens earlier listed as *F. crassipes* Wils. He also gives a full discussion of *F. crassipes* var. *Philiberti* Besch., a calcicolous plant known only from Algeria and Morocco. As a result of his studies he separates it from *F. crassipes* and describes it as a distinct species under the name *F. Philiberti* (Besch.) P. de la V.—A. W. Evans.

1133. POTTIER, M. Recherches sur le développement de la feuille des mousses. [Studies on the development of the leaf in mosses.] Ann. Sci. Nat. Bot. 3: 1-137. 32 pl. 1921.—This paper was originally issued as a separate publication and has already been abstracted [see Bot. Absts. 9, Entry 879].—A. W. Evans.

1134. THÉRIOT, I. Mousses de l'Annam, 2^e contribution. [Mosses of Annam, 2nd contribution.] Rev. Bryologique 49: 6-9. 3 fig. 1922.—The author's 1st paper on the mosses of Annam appeared in 1919 [see Bot. Absts. 4, Entry 1041]. The present paper is based on a collection made in August, 1919, by F. Vincens on Mt. Honbâ, at an altitude of 1500 m. Of the 14 species enumerated, *Homaliodendron elegantulum* and *Sematophyllum Vincensianum* are described as new and the following 3 species are recorded for the 1st time from the Asiatic continent: *Otenidium serratifolium* (Card.) Broth., *Macromitrium ceylanicum* Mitt., and *Mniodendron humile* Lindb. Critical notes accompany several of the species.—A. W. Evans.

MORPHOLOGY AND TAXONOMY OF FUNGI, LICHENS, BACTERIA,
AND MYXOMYCETESH. M. FITZPATRICK, *Editor*D. S. WELCH, *Assistant Editor*

(See also in this issue Entries 1031, 1032, 1033, 1103, 1375, 1401, 1412, 1413, 1435, 1436, 1455, 1456, 1492 and those in Section Pathology)

FUNGI

1135. ANONYMOUS. Haslemere spring foray. *Trans. British Mycol. Soc.* 7: 221-224. 1922.—The annual spring foray, which was held at Haslemere, Surrey, May 13-16, 1921, is reported and a complete list is given of the fungi collected, numbering about 232 species.—*W. B. McDougall.*

1136. ARTHUR, JOSEPH CHARLES. New species of Uredineae—XIV. *Bull. Torrey Bot. Club* 49: 189-196. 1922.—The following descriptions and nomenclatorial changes are made: *Bullaria Zorniae* (Dietel) comb. nov., *Melampsoropsis roanensis* sp. nov., *Cronartium stalactiforme* Arthur & Kern comb. nov., *Diabole* gen. nov., *D. cubensis* comb. nov., *Puccinia Pluchae* (Sydow) comb. nov., *Uredo nominata* sp. nov., *U. cumula* sp. nov., *U. curvata* sp. nov., *Aecidium Yuccae* sp. nov.—*P. A. Munz.*

1137. ARTHUR, J. C. Uredinales collected by R. Thaxter and J. B. Rorer in Trinidad. *Bot. Gaz.* 73: 58-69. *Fig. 1-4.* 1922.—The author presents a list of 41 known species and 3 new ones; *Cerotelium minutum* on undetermined Bignoniaceous host, *Puccinia corticola* on *Cordia Gerascanthus* L., and *Maravalia pallida* on *Pithecolobium latifolium* (L.) Benth. The last is the type of a new genus.—*D. S. Welch.*

1138. AZOULAY, LÉON. Détermination instantanée de la couleur des spores. [A quick method for determining spore color.] *Bull. Trimest. Soc. Mycol. France* 37: 146-148. 1921.—This may be accomplished by passing between the gills some object to which the spores will adhere. Black and white paper, cloth, feathers, or brushes are suggested. A greater quantity of spores may be obtained by means of a small water-color brush slightly moistened. In testing specimens with milky juice it is necessary to use both black and white paper, the true spore color being given by the spots on the paper which are pulverulent and easily removed by brushing with the finger. In mature specimens the spores may be caught by placing the cap, gills downward, on a smooth surface from which the spores may later be removed by brushing and transferred to a testing surface.—*D. S. Welch.*

1139. BAKER, C. F. Additions to Philippine and Malayan technical bibliography. *Philippine Agric.* 10: 363-366. 1922.—Eleven citations to mycological contributions are given which are to be added to the bibliographical list published earlier [see *Bot. Absts.* 5, Entry 1238]. The titles consist of published studies based wholly, or in part, on the material of Philippine and Malayan fungi brought together by C. F. Baker. The bibliography also contains many citations to similar entomological contributions.—*Sam F. Trelease.*

1140. BARBIER, M. Découverte du *Secotium acuminatum* Mtg. près de Dijon (Côte d'Or). [The discovery of *Secotium acuminatum* Montagne near Dijon (Gold Coast).] *Bull. Trimest. Soc. Mycol. France* 38: 29-30. *1 fig.* 1922.—A note is given on the collection of this rare fungus together with a description of the same.—*D. S. Welch.*

1141. BONAR, LEE. An albino mutation of the dematiaceous fungus *Brachysporium Trifolii*. *Science* 56: 226-227. 1922.—The dark brown hyphae lost their color in one sector of growth in a culture. For 16 non-sexual generations this strain has persisted. No sexual stage has been obtained in either the normal or the albino strain.—*C. J. Lyon.*

1142. BONNS, WALTER W. A preliminary study of *Claviceps purpurea* in culture. Amer. Jour. Bot. 9: 339-353. 6 pl. 1922.—*Claviceps purpurea* was grown in culture on agar, vegetable plugs, and various mashes. Results agree with those of previous workers except as to conditions producing certain morphological variations. A stage showing structure analogous to that of the natural sclerotium was produced. The conidial stage may develop directly from the sclerotium without germination and without the formation of ascospores. An extract of the culture-grown fungus was tested for 3 of the chief active principles of ergot—tyramine, histamine, and ergotoxine—and the presence was demonstrated of histamine only. A much larger amount of material should be grown and studied before its chemical composition can be determined with accuracy. It seems doubtful whether the artificial culture of *Claviceps* is practical commercially.—E. W. Sinnott.

1143. BOSE, S. R. Descriptions of some polypores new to Bengal. Proc. Sci. Convention Indian Assoc. Cultivation Sci. 1919: 55-62. Pl. 1-6. 1922.—The paper constitutes Part IV of Bengal Polyporaceae, which is being published serially. The following 7 species collected in different parts of Bengal are described, and figures illustrating both the upper and lower surfaces of the fruit-body are given for each: *Lenzites alutaceus*, *Polyporus rhizophorae*, *P. rigidus*, *Polystictus xanthopus*, *P. flabelliformis*, *P. suboccidentalis*, and *Trametes Meyenii*. Of these the 4th and 5th were also collected in Madras.—S. R. Bose.

1144. BOSE, S. R. Polyporaceae of Bengal. Part V. Bull. Carmichael Medical College 3: 20-25. Pl. 1-9. 1922.—Twelve species representing the genera *Fomes*, *Polyporus*, *Polystictus*, *Trametes*, and *Daedalea*, collected in Bengal, Assam, and Madras, are described and figured.—S. R. Bose.

1145. BRÉBINAUD, P. Bolets à pores rouges et Russules rouges. [Red pored Boleti and red Russulas.] Bull. Trimest. Soc. Mycol. France 37: 149-155. 1921.—*Boletus purpureus* (Fr.) is described with synonymy. Changes in color of pileus are due to variations in moisture. This also applies to other fungi with flesh changing color on exposure to air. Among certain species of *Russula* external conditions appear to govern the amount of coloring on the pileus. The formation of reticulations and dots at the base of the stipe in Boleti is due to the rupturing of the tubes or hyphae which in the beginning are attached to the base of the stipe. Thus the coloring of the reticulations and of the pores in the younger stages is believed to be a process of oxidation of freshly exposed tissue. Two types of subterranean mycelia are distinguished, one nutritive, the other for respiration. In the ground the mycelium is found mostly in holes made by insects or in areas loosened by burrowing animals or other agencies.—D. S. Welch.

1146. BROOKS, R. ST. JOHN. The national collection of type cultures. Trans. British Mycol. Soc. 7: 237-239. 1922.—The national collection of type cultures which is located at the Lister Institute of Preventive Medicine was formed in January 1921 and since that time "some twelve hundred strains of microorganisms of medical, veterinary and economic importance have been incorporated in the collection and cultures have been distributed to workers at home and abroad at the rate of about two thousand per annum." More recently the scope of the national collection has been extended to include cultures of representative fungi.—W. B. McDougall.

1147. BULLER, A. H. R. The basidial and Oldial fruit-bodies of *Dacryomyces deliquescentis*. Trans. British Mycol. Soc. 7: 226-230. 1921.—*Dacryomyces deliquescentis* produces 2 kinds of fruit-bodies, one orange colored and bearing oidia, the other yellow and producing basidiospores. These 2 kinds of fruit-bodies were originally described as separate species, and in order to clear up the confusion arising from this fact the plant is here redescribed in detail.—W. B. McDougall.

1148. BURT, E. A. Some North American Tremellaceae, Dacryomycetaceae, and Auriculariaceae. Ann. Missouri Bot. Gard. 8: 361-396. Pl. 3, figs. 1-6. 1921.—Burt has compared

Vermont collections with authentic specimens of tremellaceous fungi in the Schweinitz herbarium and has studied species in this group described by Berkeley & Curtis, Peck, and others. His notes are presented on 16 species included in the Tremellaceae, 9 in the Dacryomycetaceae, and 4 in the Auriculariaceae. *Heterochaete microspora*, *Auricularia rosea*, and *Helicobasidium Peckii* are described as new species, while there are 9 new combinations, in which *Peziza concrescens* Schw. becomes *Tremella concrescens* Schw. Burt, *Exidiopsis alba* Lloyd becomes *Exidia alba* (Lloyd) Burt, *Tremella nucleata* Schw. becomes *Exidia nucleata* (Schw.) Burt, *Tremella aurantia* Schw. becomes *Naematelia aurantia* (Schw.) Burt, *Sebacina Sheari* Burt becomes *Heterochaete Sheari* Burt, *Tremella palmata* Schw. becomes *Dacryomyces palmatus* (Schw.) Burt, *Tremella subochracea* Peck becomes *Dacryomyces subochracea* (Pk.) Burt, *Tremella stipitata* Peck becomes *Dacryomitra stipitata* (Peck) Burt, and *Exidia pedunculata* Berkeley & Curtis becomes *Dacryomitra pedunculata* (B.&C.) Burt.—S. M. Zeller.

1149. BURT, E. A. The North American species of *Clavaria*, with illustrations of the type specimens. Ann. Missouri Bot. Gard. 9: 1-78. Pl 1-11. 1922.—In this contribution Burt gives helpful suggestions to collectors of coral fungi. In the various sections of North America collections should be taken with careful records as to color, odor, taste, and spore characters of fresh specimens. Colors should be standardized by comparison with some chart, as Ridgway's, and spore collections made in some standard way, as on glass, with records of the color values *en masse* when fresh. Mature specimens which shower spores freely are much preferred to the immature collections which often "clutter up herbaria and waste valuable time." Burt has brought together the original descriptions (together with his notes) of North American species, their spore characters, and photographic illustrations of the type specimens. Notes on such exotic species from South America and the North Pacific Exploring Expedition as were available for examination have been appended. Among the 98 accepted North American species *Clavaria pinicola*, *C. flavuloides*, *C. mutans*, and *C. pilosa* Burt are described as new. Sixteen species with the original descriptions are listed as "imperfectly known." Eight "excluded species" include new combinations in which *Clavaria ornatipes* Peck becomes *Lachnocladium ornatipes* (Peck) Burt, *Clavaria subcorticalis* Schw. becomes *Lachnocladium subcorticale* (Schw.) Burt, *Clavaria vestipes* Peck becomes *Lachnocladium vestipes* (Peck) Burt, *Clavaria tenax* Schw. becomes *Tremellodendron tenax* (Schw.) Burt, and *Clavaria Typhuloides* Peck becomes *Pistillaria Typhuloides* (Peck) Burt. Six exotic species are listed.—S. M. Zeller.

1150. CORTINI, JONE COMANDUCCI. *Tylomyces gummiparus* n. sp. prototipo di un nuovo genere di Ifomiceti. Caratteri morfologici. Nota I. [*Tylomyces gummiparus* n. sp. prototype of a new genus of the Hyphomycetes. Morphological characters. Note I.] Atti R. Accad. Lincei Roma Rendiconti (Cl. Sci. Fis. Mat. e Nat.) 30²: 63-66. Fig. 1-14. 1921.—A hyphomycetous fungus referable to the family Dematiaceae, section Phragmosporae, was found growing saprophytically on *Dianthus Caryophyllus*. The aerial mycelium is more or less covered with irregular brownish scales or plates. The conidia are borne in chains and are formed mesendogously as recently described by Peyronel for another fungus [see Bot. Absts. 12, Entry 1187]. The chains of conidia are peculiar in that the end of one conidium is commonly attached to the side of the next.—F. M. Blodgett.

1151. CORTINI, JONE COMANDUCCI. *Tylomyces gummiparus*. n. sp. prototipo di un nuovo genere di Ifomiceti. Caratteri biologici e sistematica del fungo. Nota II. [*Tylomyces gummiparus* n. sp. prototype of a new genus of Hyphomycetes. Biologic and systematic characters of the fungus. Note II.] Atti R. Accad. Lincei Roma Rendiconti (Cl. Sci. Fis. Mat. e Nat.) 30²: 113-116. Fig. 15-33. 1921.—The germination of the conidia of *Tylomyces gummiparus* is described in some detail. This fungus is readily grown in culture without losing its characteristic form. Systematically it resembles *Fusariella* Sacc., but the peculiar chains of spores and the scale-like covering of the mycelium leads the author to describe it as the type of a new genus.—F. M. Blodgett.

1152. COURTILLOT, J. Observations sur quelques champignons de la vallée supérieure de la Saône. [Some fungi of the upper Saone valley.] Bull. Trimest. Soc. Mycol. France 38: 31-33. 1922.—Brief notes are given with special reference to odor, taste, and habitat on certain species from the following genera: *Tricholoma*, *Clitocybe*, *Collybia*, *Hygrophorus*, *Russula*, *Pleurotus*, *Hypoloma*, *Coprinus*, *Boletus*, and *Phallus*.—D. S. Welch.

1153. CRÉPIN, CH. Un *Oidium* de la betterave. [An *Oidium* of the beet.] Bull. Soc. Path. Vég. France 9: 118-119. 1 fig. 1922.—The conidia are the same length as those of *Microsphaera Betae* but narrower.—J. Dufrenoy.

1154. DAVIS, W. H. *Urocystis Agropyri* on redtop. Mycologia 14: 279-281. 1 fig. 1922.—The author reports the occurrence of *Urocystis Agropyri* on *Agrostis palustris* collected in Wisconsin, and describes the sori and spores.—H. R. Rosen.

1155. DODGE, B. O. A *Lachnea* with a botryose conidial stage. Bull. Torrey Bot. Club. 49: 301-305. Fig. 1-7. 1922.—*Lachnea abundans* Karst. has asexual fructifications closely resembling *Botrytis*, the connection between the apothecial and conidial stages having been repeatedly established. The suggestion is made that "it is certainly dangerous to place too much weight on the asexual spore forms in determining relationship of their ascogenous stages."—P. A. Munz.

1156. DODGE, B. O. Studies in the genus *Gymnosporangium*. IV. Distribution of the mycelium and the subcuticular origin of the telium in *G. clavipes*. Amer. Jour. Bot. 9: 354-365. 1 pl., 7 fig. 1922.—Primary infection of *Gymnosporangium clavipes* on *Juniperus virginianum* occurs in the cuticularized layer of the epidermal cells of leaves and young stems. As the season advances, the hyphae penetrate into the mesophyll. In cork-covered stems the parasite is generally confined to the 2 or 3 outermost cell layers of the cortex. The main trunk may become infected by downward growth of hyphae from an infected branch. Characteristic binucleate haustoria occur in the cells of the epidermis and mesophyll. The first sori always appear either directly on the leaves or, more commonly, on the stems at the margins of the decurrent leaf bases or in the leaf axils. In later years, as cork is laid down on the stem, the sori are formed and break through in the ordinary manner. Sori on leaves and young stems are subcuticular to the extent that they arise in the cuticularized layer of the epidermal cells. As in other species studied by the author, the teliospore buds grow out from the subterminal cells of the basal primordium. The terminal cells, having become disorganized and swollen, function as buffer cells.—E. W. Sinnott.

1157. DOIDGE, ETHEL M. South African Ascomycetes in the National Herbarium. Part 2. Bothalia 1: 65-82. Fig. 1-8. 1922.—Thirty-five fungi are described including the following new species: *Catacauma Schotiae*, *Dictyochorella Andropogonis*, *Phyllachora Tecleae*, *P. myrsinicola*, *Telimena Arundinariae*, *T. corticola*, *Systemma Pterocarpi*, *Meliola Carissae*, *M. oleicola*, *M. gemellipoda*, *Calothyrium Psychotriae*, *Asterina Crotonicola*, *A. Scolopiae*, *Lembosia priensis*, *Trichopeltula Carissae*, *T. kentaniensis*, *Scolecopeltis Cassipoureae*, *Asterinella Minusopsidis*, *Irene Rinorea*, *I. Zeyheri*, *Clypeosphaeria natalensis*.—E. M. Doidge.

1158. DOSDALL, LOUISE. Occurrence of the pycnial stage of *Puccinia Taraxaci*. Bull. Torrey Bot. Club 49: 235-236. 1922.—The pycnial stage of *Puccinia Taraxaci* (Rabent.) Plow. is reported from Minnesota and Indiana and a description is given.—P. A. Munz.

1159. ELLIOTT, JESSIE S. BAYLISS. Studies in discomycetes. III. Trans. British Mycol. Soc. 7: 293-298. Fig. 1-2. 1922.—Ten species of discomycetes found in England are discussed.—W. B. McDougall.

1160. ELLIOTT, JOHN A. Some characters of the southern tuckahoe. Mycologia 14: 222-227. Pl. 17-18, fig. 1-2. 1922.—Clamp connections are noted on the mycelium, suggest-

ing a basidiomycete. A cut sclerotium imbedded in a greenhouse bench and later dug out showed a blackish root-like growth from the cut surface. When broken this rhizomorph exuded a milky fluid. Cultures from the peripheral regions of the sclerotium on cornmeal agar appeared as dark-brown, sterile, felty growths. Microscopic sections of the sclerotium show lactiferous ducts and glands.—*H. R. Rosen.*

1161. FAIRMAN, CHARLES E. New or rare fungi from various localities. *Proc. Rochester Acad. Sci.* 6: 117-139. *Pl.* 21-23. 1922.—The following are described as new: *Phomopsis rubiseda*, *P. fraterna*, *P. Trollii*, *Dendrophoma nigrescens*, *Sphaeronema epicaulon*, *Cytospora Nyssae*, *Sphaeropsis subconfluens*, *S. Opuntiae*, *Coniothyrium praeclarum*, *Didymochaeta columbiana*, *Microdiplodia ilicigena*, *Stagonospora nyssaecola*, *Hendersonia Arundinariae*, *Rhabdospora ilicigena*, *R. cryptosporopsis*, *Leptostroma Mitchellae*, *Heteropatella acerina*, *Discella zythiacea*, *Didymosporium propolidioides*, *Scolecosporium transversum*, *Graphium sordidiceps*, *Anthostomella endoryloides*, *Diaporthe Hamamelidis*, *Didymosphaeria Lonicerae* var. *riparia*, *Melanomma nigriseda*, *Leptosphaeria lyciophila*, *L. Hamamelidis*, *L. pseudohleria*, *Sporormia ourasca*, *Cucurbitaria rimulina*, *Gloniopsis Lathamii*, *G. Lathamii* var. *asymetrica*, *Clasterosporium larviforme*, *Hendersonia foliorum* var. *hamamelidina*, *Cladosporium punctulatum* var. *xylogenum*, *Stemphylium subsphaericum*, *Exosporium scolecomorphum*, *Phoma Dioscoreae*. Two new genera, *Gamonaemella* and *Amblyosporiopsis*, each represented by a single new species, *G. divergens* and *A. parasphenoides* respectively, are described. The 1st differs from *Gamospora* in having smooth pycnidia, the 2nd differs from *Amblyosporium* in having the conidiophores apically dilated into heads and in having spores truncate only at one end.—*H. M. Fitzpatrick.*

1162. FAIRMAN, CHARLES E. The fungi of our common nuts and pits. *Proc. Rochester Acad. Sci.* 6: 73-115. *Pl.* 15-20. 1921.—The following new species or varieties are described: *Phomopsis carposchiza*, *Macrophoma Fitzpatrickiana*, *Rhabdospora baculum* var. *nucimaculans*, *Vermicularia exocarpinella*, *V. putaminicrustans*, *Pyrenochaeta nucinata*, *Dothiorella nucis*, *Sphaeropsis pallidula*, *Diplodina epicarya*, *Stagonospora nuciseda*, *S. nucicidia*, *Pestalozzia nuciseda*, *Voluella caryogena*, *Cylindrium gossypinum*, *Monosporium avellaneum*, *Septocylindrium nuculinum*, *Coniosporium nucifoedum*, *Didymella nucis-hicoriae*, *Melanopsamma Amphisphaeria* var. *carpogena*, *M. subrhombispora*, *Didymosphaeria nuciseda*, *Rhyncostoma nucis*, *Amphisphaeria nucidoma*, *Zignoella nucivora*, *Rhynchosphaeria nucicola*, *Leptosphaeria exocarpogena*, *L. cacuminispora*, *Karschia elaeospora*. *Sphaeropsis Aesculi* Faut. & Roum. is transferred to the genus *Haplosporella*. A new genus, *Schizocapnodium* is described. Its affinities are in doubt, but it is placed near the Capnodiaceae. The spore split longitudinally, the halves falling apart. Many previously described species are here discussed.—*D. S. Welch.*

1163. FERDINANDSEN, C. En Blomkaalssvamp inden Dore (*Coniophora puteana*). [An indoor development of a fungus resembling Sparassis.] *Meddelel. For. Svampek. Fremme* 2: 104-105. 2 pl. 1920.—The author discusses a monstrosity of *Coniophora puteana* found growing on pine and spruce timbers under a floor. The largest specimens measured 9×6½ cm., weighed only 8.2 gm., and resembled a dry sponge in appearance.—*C. Ferdinandsen.*

1164. FERDINANDSEN, C., OG Ø. WINGE. En ny Kampeform af Elme Østershat (*Pleurotus ulmarius* (Bull.) Fr. f. *gigantea* nov. form.). [A new giant form of *Pleurotus ulmarius*.] *Meddelel. For. Svampek. Fremme* 2: 101-103. 1 fig. 1920.—The authors figure and give a Latin description of this monstrous agaric. The pileus reaches a diameter of 37 cm. and the stipe attains a length of 67 cm. The fungus was found in 3 succeeding years, late in autumn, in a Danish park. The fruit-bodies were partly hidden in, and partly emerging from, cavities in an old elm tree.—*C. Ferdinandsen.*

1165. FRASER, W. P. Cultures of heteroecious rusts, 1920-1921. *Mycologia* 14: 228-230. 1922.—"Inoculations with teliospores from *Spartina pectinata* Bosc. produced pycnia and

aecia on *Glaux maritima* L.," adding a new aecial host to *Puccinia Distichlidis*. Teliospores from *Distichlis stricta* produced pycnia and aecia on *Glaux maritima* and *Plantago eriopoda*, adding 2 new aecial hosts to the "pluriverous" rust, *Puccinia subnitens*.—H. R. Rosen.

1166. GRAFF, PAUL W. **Philippine Basidiomycetes**—V. Bull. Torrey Bot. Club 49: 223-233. 1922.—The Polyporeae are completed and records are given for many species. *Daedalea versatilis* (Berk.), *Hexagonia Clemensiae* (Murr.), *H. subrubida* (Murr.), and *Gloeoporus reticulatus* (Fr.) are published as new combinations. In the Agaricineae various notes are given.—P. A. Munz.

1167. HASLER, ALFRED. Über die Entwicklungsgeschichte einiger Rostpilze. [On the life-histories of certain rusts.] Centralbl. Bakt. II. Abt. 54: 35-50. 1921.—The paper describes cultural studies on *Puccinia Lactucarum* and the following *Carex* rusts: *Puccinia serratulae-caricis* Kleb. on *Carex fulva* and *C. flava*; *P. urticae-pilosae* forma specialis on *Carex pilosa* and *C. frigida*; and *P. urticaefrigidae* on *Carex frigida* and *C. ferruginea*.—M. A. Raines.

1168. HEDGCOCK, GEORGE G., AND N. REX HUNT. Notes on some species of *Coleosporium* —I. Mycologia 14: 244-257. Pl. 20-21. 1922.—In order to prove or disprove the theory that species of pine act as bridging hosts for different species of *Coleosporium*, numerous inoculations were made, some of which are now recorded. It is shown that aeciospores and urediniospores of *C. Helianthi* can infect numerous species of *Helianthus*, but do not infect other composites, and in particular it was found that various species of *Coreopsis* were not infected. Likewise, aeciospores and urediniospores of *Coleosporium inconspicuum* infected only species of *Coreopsis*. This indicates that *Coleosporium Helianthi* and *C. inconspicuum* are distinct species. It is also found that *C. Helianthi* has a much wider distribution. The pycnial and aecial stages of *C. terebinthinaceae* and *C. laciniariae* are compared, and hosts of the former species are presented together with the geographic distribution. Numerous inoculation experiments with *C. delicatulum* indicate that only species of *Euthamia* act as uredinial and telial hosts and that various species of *Pinus* are susceptible. A list of hosts and geographic distribution are given for this species.—H. R. Rosen.

1169. HÖHNEL, F. VON. Vierte vorläufige Mitteilung mycologischer Ergebnisse (Nr. 305-398). [Fourth preliminary report of the results of mycological investigations.] Ber. Deutsch. Bot. Ges. 37: 107-115. 1919.—In this continuation of notes from Vol. 36 of this publication the author lists many genera and species with changes and corrections in synonymy. The names of the following genera appear: *Agaricus* (*Tricholoma*), *Russula*, *Peziza*, *Ungicularia*, *Urceolella*, *Niptera*, *Pyrenopeziza*, *Mollisia*, *Dermatella*, *Cenangella*, *Belonidium*, *Tapesina*, *Chalara*, *Polydesmia*, *Leptobelonium*, *Belonium*, *Trichobelonium*, *Niesslella*, *Belonopsis*, (there is no morphological basis for the family *Caliciaceae*), *Stenocybe*, *Beloniocypha*, *Scelobelonium*, *Caliciopsis* (*Coryneliaceae*), *Capnodiella*, *Hypsotheca*, *Sorica*, *Sphinctrina*, *Phialea*, *Cyphelium*, *Scleroderis*, *Acolium* (*Cenangiaceae*), *Calicium*, *Coniocybe*, *Neolecta*, *Biatorella*, *Tromera* (*Helotiaceae*), *Steinia*, *Comesia* (*Comesiella*), *Patellea* *Tapesia*, *Helotium*, *Patinella*, *Pseudohelotium*, *Tympanis*, *Godronia*, *Asterocalyx*, (*Tryblidiaceae*), *Arachnopeziza*, *Gorgoniceps*, *Eriopeziza* (*Trichopezizaceae*), *Pezizella*, *Ctenoscypha*, *Habrostictis*, *Pseudopeziza*, *Excipula*, *Orbilbia*, *Orbiliopsis*, *Mollisia*, *Calycellina*, *Helotiopsis*, *Eubelonis*, *Phialina*, *Lachnobelonium*, *Dasysecypha*, *Dasypezis*, *Psilachnum*, *Dyslachnum*, *Tubereularia*, *Beloniella*, *Belonopeziza*, *Cenangium*, *Nectria* (*Gibbera*), *Nitschkia*, *Melanomma*, *Phyllachora*, *Polystigma*, *Clypeostigma*, *Echusias*, *Fracchiaca*, *Asterella*, *Microthyrium*, *Microthyriella*, *Myriocopron*, *Ellisiodothis*, *Microdothella*, *Melanobasidium*, *Calothyrium*, *Leptopeltis*, *Palawania* (*Polystommellaceae*), *Seynesia*, *Phragmothyrium*, *Calothyriopsis*, *Clypeolella*, *Lichenopeltella*, *Leptopeltella*, *Didymella*, *Othiella*, *Keissleriella* (*Cucurbitariaceae*), *Eriosphaeria*, *Melanopsamma*, *Melanopsammella*, *Gonytrichum*, *Acrospermum*, *Bombardiastrum*, *Cyanoderma*, *Barya*, *Torru-biella*, *Ophionectria*, *Tubeufia*, *Physosporrellaceae* n. fam. (*Sphaeriaceae*), *Pemphidium*, *Merillio-peltis*, *Oxydothis*, *Griphosphaeria*, *Anisostomula*, *Physospora*, *Ceriospora*, *Lejosphae-*

rella, *Miyakeamyces*, *Calonectria* (*Puttemansia*), *Diaporthe*, *Othia*, *Cucurbitaria*, *Diatrype*, *Valsa* (*Leucostoma*), *Kalmusia*, *Leptosphaeria*, *Nodulisphaeria*, *Sphaeria*, *Sphaerella*, *Laestadia*, *Phacidium*, *Gnomonia*, *Ditopella*, *Rehmiella*, *Scleroplella*, *Discochora*, *Physalospora*, *Carlia*, *Phaeobotryon*, *Macrophoma* (*Coleophoma*), *Macrospora*, *Clathrospora*, *Rehmiellopsis*, *Mycosphaerella*, *Diplosphaerella*, *Hariotia*, *Hypostegium* *Catacauma*, *Fusarium*, *Cryptosporium*, *Phyllosticta*, *Glocosporium*, *Aulacostroma*, *Lembosiodothis*, *Zignoëlla*, *Gilletiella*, *Haplothe-ciella*, *Cladosporium*, *Stilbum*, *Dacryomyces*, *Dendrodochium*, *Microdiscula*, *Dendrophoma*, *Blennoria*, *Phyllostictina*, *Asteromella*, *Plectophoma*, *Stictochorella*, ***Dasystictella***, *Dasysticta*, *Aposphaeria*, *Cylindrophoma*, *Coleophoma* *Ceuthospora*, *Phoma*, *Septoria*, *Sphaeropsis*, *Hender-sonia* (*Sphaerospora*), ***Naemostroma***, *Hysterium*, *Sclerophoma*, *Sporonaema*, *Discella*, *Gloeosporium*, *Discosporium*, *Pezizala*, *Ocellaria*, *Tuberculariella*, *Melanconis*, ***Discosporina***, *Hymenula*, *Gloeosporidium*, ***Myxosporina***, *Hysterostegiella*. In addition to the new genera included above (bold-faced type) the following new species are mentioned: *Keissleriella Aesculi*, *Acrospermum Adeanum*, *Othia Rubi*.—D. S. Welch.

1170. KILLERMANN, S. *Funde von einigen Britzelmayrschen Cortinari.* [Discovery of some of Britzelmayr's species of *Cortinarius*.] *Krypt. Forsch. Bayer. Bot. Ges. München* 5: 361-362. 1920.—During the last decade of the 19th century Britzelmayr described 72 new species of *Cortinarius*, most of which are now regarded as forms of previously described species. In the author's opinion, however, the following are valid: *C. albidocyaneus*, *C. apparens*, *C. disputabilis*, *C. evestigatus*, *C. odorifer*, *C. percognitus*, and *C. unimodus*. These species, together with *C. Cookei* Quél. and *C. splendidus* Peck, are briefly described from Bavarian material.—A. W. Evans.

1171. KILLERMANN, S. *Morcheln und andere Helvellaceen aus Bayern.* [Morels and other Helvellaceae from Bavaria.] *Krypt. Forsch. Bayer. Bot. Ges. München* 3: 148-154. 1 fig. 1918.—Following the example of Rehm, the author divides the Bavarian Helvellaceae upon which his report is based into the Rhizineae, the Geoglosseae, and the Helvelleae. Under the Rhizineae he lists a single species; under the Geoglosseae, 13 species in 9 genera; and under the Helvelleae, 22 species in 3 genera. Each species is accompanied by data regarding stations and collectors, by references to the literature, and usually by critical or descriptive notes. The figure represents a new form of *Mitrlula Rehmi* Bres., but no other novelties are described.—A. W. Evans.

1172. KILLERMANN, S. *Nachtrag zu meinen trüffel- und Morchelfunden.* [Additions to my discoveries of truffles and morels.] *Krypt. Forsch. Bayer. Bot. Ges. München* 4: 335-336. 1919.—The author publishes notes on 3 hypogaeous fungi and 4 members of the Helvellaceae found in various parts of Bavaria, 2 of which represent additions to the flora.—A. W. Evans.

1173. KILLERMANN, S. *Ueber den Hexenpilz (Boletus luridus Schöff.) und Verwandte.* [On the witch fungus (*Boletus luridus*) and its allies.] *Krypt. Forsch. Bayer. Bot. Ges. München* 4: 336-343. 3 fig. 1919.—The author discusses certain Bavarian species of *Boletus* belonging to the groups *Luridi* and *Colpodes* of Fries. In the 1st group he recognizes *B. luridus* Schaff., *B. rubeolaris* Bull., and *B. Satanus* Lenz as valid and, in the 2nd group, *B. pachypus* Fr., *B. calopus* Fr., and *B. torosus* Fr., although he expresses the opinion that the last may perhaps be a young form of *B. Satanus*. Under *B. rubeolaris* he includes *B. Lorinseri* G. Beck and *B. suspectus* as synonyms and *B. erythropus* (Pers.) Fr. as a variety, and under *B. Satanus* includes *B. macrosporus* Britzelmayr as a synonym and *B. lupinus* Fr. as a variety. The status of *B. appendiculatus*, *B. terreus*, and *B. olivaceus*, species proposed by Schäffer, is not altogether certain. The 1st, however, may be a form of the variable *B. subtomentosus* L., while the other 2 probably represent *B. calopus*. Full references to the literature accompany the article.—A. W. Evans.

1174. KINZEL, WILHELM. *Über Hexenringe und die Bedingungen ihrer Entstehung.* [On fairy rings and the conditions necessary for their formation.] *Krypt. Forsch. Bayer. Bot.*

Ges. München 3: 154-164. 1918.—The author describes the appearance of the so-called "fairy rings," caused for the most part by basidiomycetous fungi, and shows how they increase in size. He then discusses the conditions necessary for their formation and compares them with the rings of growth formed in artificial cultures by *Monilia fructigena* and similar fungi. The infection experiments carried out in the open by Münch, whereby fairy rings were artificially produced, bring out some of the most striking similarities between these 2 types of growth. At the close of the paper 22 species of fungi, associated with the formation of fairy rings, are enumerated.—A. W. Evans.

1175. KRIEGER, LOUIS C. C. Common mushrooms of the United States. Nation. Geog. Mag. 37: 387-439. 16 pl., 38 fig. 1920.—A non-technical discussion of mushrooms with descriptions is given as a basis for identification. Emphasis is placed on the question of edibility.—W. M. Atwood.

1176. MACCALLUM, B. D. Some wood-staining fungi. Trans. British Mycol. Soc. 7: 231-236. Pl. 8-9. 1922.—A brief historical review is followed by an account of the life history of *Ceratostomella Piceae*. Evidence is presented in support of the view that *Graphium penicillioides* is a stage in the life history of *Ceratostomella Piceae*.—W. B. McDougall.

1177. MAGNIN, HENRI. Récolte printanière de *Psalliota campestris* L. [An early collection of *Psalliota campestris*.] Bull. Trimest. Soc. Mycol. France 38: 56. 1922.—This fungus appeared March 15 in a garden which had been heavily manured the preceding November.—D. S. Welch.

1178. MANGENOT, G. A propos de quelques formes peu connues d'Endomycétacées. [Concerning some little known Endomycetaceae.] Bull. Trimest. Soc. Mycol. France 38: 42-55. Pl. 1-2, fig. 1. 1922.—*Endomyces Javanensis* Klöcker has a yeast-like mycelium and produces asci without a sexual process. *Endomyces Lindneri* Saito is typically parthenogenetic, but cases are found varying from permanent fusion of gametes (without nuclear fusion) to total absence of gametes. Parthenogenetic gametes frequently develop an ascogenous hypha, often only a single cell. This perhaps indicates the place of origin of this structure in the phylogeny of the Ascomycetes. *Endomyces Hordei* is closely related to the above but is always parthenogenetic.—D. S. Welch.

1179. MARTIN, GEORGE W. Rhizophidium Polysiphoniae (Cohn) Peterson in the United States. Bot. Gaz. 73: 236-238. Fig. 1-10. 1922.—The author reports the occurrence of and describes the above species from a specimen of *Callithamnion* received from Barnegat Bay, New Jersey.—B. W. Wells.

1180. MAYOR, EUG. Une espèce biologique nouvelle du type de *Puccinia sessilis* Schneider. [A new biologic species of *Puccinia sessilis*.] Bull. Trimest. Soc. Mycol. France 38: 34-41. 1922.—*Puccinia Smilacearum-Festucae* is described with the following hosts: O and I found in nature on *Paris quadrifolia*, *Convallaria majalis*, *Polygonatum multiflorum*, *P. verticillatum*, and obtained in culture on *P. officinale*. The acedial stage shows no biologic specialization. II and III develop only on *Festuca sativa*.—D. S. Welch.

1181. MOUNCE, IRENE. Homothallism and heterothallism in the genus *Coprinus*. Trans. British Mycol. Soc. 7: 256-269. 1922.—In continuing her previous studies on the genus *Coprinus*, the author concludes that *Coprinus sterquilinus* and *C. stercorarius* are homothallic whereas *C. lagopus* and *C. niveus* are heterothallic. Both of the latter probably sometimes give rise to homothallic strains.—W. B. McDougall.

1182. MURRILL, WILLIAM A. Dark-spored agarics—III. Agaricus. Mycologia 14: 200-221. 1922.—This is a key to 30 species of *Agaricus* with a description of each. Three new species are recognized: *A. alabamensis*, *A. comtuliformis*, and *A. rubribrunnescens*.—H. R. Rosen.

1183. MURRILL, WILLIAM A. Dark-spored agarics—IV. *Deconica*, *Atylospora*, and *Psathyrella*. *Mycologia* 14: 258-278. 1922.—The present article deals with dark-spored agarics having a slender, tubular stipe with cartilaginous cortex, and not furnished with an annulus. Those having decurrent gills are placed in the genus *Deconica*, 9 species being listed, including *D. tomentosa* sp. nov., *D. polytrichophila* (Peck) comb. nov., and *D. pyrispora* sp. nov. Of the forms having adnate or adnexed gills those with purplish-brown or dark-fuscous spores are placed in the genus *Atylospora* (*Psathyra*), in which 7 species are recognized: *A. microsperma* (Peck) comb. nov., *A. vestita* (Peck) comb. nov., *A. multipedata* (Peck) comb. nov., *A. prunuliformis* sp. nov., *A. australis* sp. nov., *A. umbonata* (Peck) comb. nov., and *A. striatula* sp. nov. Seventeen black-spored species are placed in *Psathyrella*, including *P. castaneicolor* sp. nov., *P. petasiformis* sp. nov., and *P. distantifolia* sp. nov.—H. R. Rosen.

1184. OVERHOLTS, L. O. Mycological notes for 1920. *Bull. Torrey Bot. Club* 49: 163-173. Pl. 9, fig. 1-14. 1922.—Notes and records are given for *Zythia resinæ* (Ehrenb.) Karst., *Biotorella resinæ* (Fr.) Mudd, *Pilacre Petersii* B. & Br., *Tulasnella Violæ* (Quél.) Boud. & Gal., *Dacryomyces hyalina* Quél., *Stereum radiatum* Peck, *Merulius fugax* Fr., *Solenia fasciculata* (Pers.) Fr., *Polyporus caeruloporus* Peck, and *Fomes Bakeri* Murrill. *Polyporus compactus* is described as a new species.—P. A. Munz.

1185. PAUL, H. Vorarbeiten zu einer Rostpilz- (Uredineen-) Flora Bayerns. 2. Beobachtungen aus den Jahren 1917 und 1918, sowie Nachträge zu 1915 und 1916. [Preliminary studies for a rust flora of Bavaria. 2. Observations for the years 1917 and 1918, as well as additions for 1915 and 1916.] *Krypt. Forsch. Bayer. Bot. Ges. München* 4: 299-334. 1919.—The 1st paper of this series, dealing with observations on the rust flora of Bavaria for the years 1915 and 1916, appeared in 1917. In the 2nd paper most of the observations recorded are for 1917 and 1918 although a few of earlier date are included. The species listed total 281 and increase the number of rusts now known in Bavaria to over 300. The genera recognized number 21, those best represented being *Puccinia*, *Uromyces*, and *Melampsora*. Each species is accompanied by full data regarding stations, collectors' names, dates, host-plants, and (where necessary) types of spore-forms collected.—A. W. Evans.

1186. PEYRONEL, BENIAMINO. Nouveaux cas de rapports mycorrhiziques entre Phanerogames et Basidiomycètes. [Mycorrhizal relationships between phanerogams and basidiomycetes.] *Bull. Trimest. Soc. Mycol. France* 37: 143-146. 1921.—It is believed that the number of fungi producing mycorrhizae is great. About 20 basidiomycetes have been reported. In an unpublished note the author has pointed out 13 more and in the present paper is given an additional list of 19, mostly from the genera *Amanitopsis*, *Russula*, *Lactarius*, and *Boletus*. Depending upon the nature of the terrain as much as the individual species, both macroscopic and microscopic methods are employed to determine the connection between the mycorrhizal covering (mycochlène) on the host and the hymenophore of the fungus.—D. S. Welch.

1187. PEYRONEL, BENIAMINO. Un ifomicete dai conidi mesoendogeni: *Menispora microspora* n. sp. [A hyphomycete with mesoendogenous conidia: *Menispora microspora* n. sp.] *Atti R. Accad. Lincei Roma Rendiconti (Cl. Sci. Fis. Mat. e Nat.)* 30⁴: 29-32. Fig. 1-12. 1921.—A hyphomycetous fungus found on chestnut bark is described as *Menispora microspora* n. sp., being distinguished by the small size of the conidia. The latter measure $10-12 \times 1.5-2.25\mu$ for the most part. Flask-shaped bodies (conidiogenes) with a funnel-shaped neck (stomidium) are borne principally at the tips of the conidiophores. The conidia are formed from the protoplasm of the conidiogene, the protoplasm being forced out through the neck to form the spores one after another. These the author calls mesoendogenous conidia.—P. M. Blodgett.

1188. ROSEN, H. R. *Tilletia texana* in Missouri. *Ann. Missouri Bot. Gard.* 8: 357-359. 1921.—The occurrence of this species in Missouri is cited and notes of a monographical nature are given.—S. M. Zeller.

1189. ROSTRUP, OVE. To for Danmark nye Pigsvamp-Arter. [Two *Hydnum* species new to Denmark.] Meddelel. For. Svampek. Fremme 2: 93-95. 2 fig. 1920.—The species in question are *H. aurantiacum* Fr. and *H. friabile* nov. nom. The latter has hitherto been called *H. fragile*. The author gives arguments for the necessity of a new name.—*C. Ferdinandsen*.

1190. SEAVER, FRED J. Studies in tropical Ascomycetes—I. *Neopectia diffusa* and *Herpotrichia albidostoma*. Mycologia 14: 235-238. Pl. 19. 1922.—Synonyms and description of each species are given. The genus *Neopectia* is said to differ from *Herpotrichia* "in that the spores are never more than 1-septate while in the latter they show a tendency to become more than 1-septate."—*H. R. Rosen*.

1191. SHEAR, C. L. Life history of an undescribed ascomycete isolated from a granular mycetoma of man. Mycologia 14: 239-243. 3 fig. 1922.—Crushed granules from diseased tissue of an ankle showed fungus hyphae to be present. Transfers to culture media gave apparently pure cultures of the fungus, although no successful infections resulted when inoculated into guinea pigs. The fungus grows readily on ordinary culture media such as cornmeal agar and in a few weeks produces 3 spore forms, 2 conidial and 1 perithecial. The 1st to appear is a *Cephalosporium* stage, named *C. Boydii*, followed by the perfect stage, *Allescheria Boydii*, which in turn is followed by a coremial form, *Dendrostilbella Boydii*. In the technical description of the fungus the author adopts a system of Roman numerals for the various stages somewhat comparable to the manner in which these are used by uredinologists. Thus I indicates an ascogenous fructification, II a pycnidial stage, III a conidial form; and when more than one pycnidial or conidial form occurs in the life cycle this is indicated by an alphabetical exponent, as III^a and III^b.—*H. R. Rosen*.

1192. SOUTH, F. W. An important root disease on Borneo camphor. Agric. Bull. Federated Malay States 9: 34-36. 1921.—An account is presented of *Rosellinia bunodes* attacking *Dryobalanops Camphora*.—*I. H. Burkill*.

1193. TANAKA, TŌZABURŌ. New Japanese fungi—Notes and translations—XII. Mycologia 14: 282-295. 1922.—The following species of *Gymnosporangium* are described: *G. asiaticum* Miyabe with pycnia and aecia on *Pyrus sinensis* and *Cydonia vulgaris* and telia on *Juniperus chinensis* and *J. chinensis* var. *procumbens*; *G. Yamadae* Miyabe with pycnia and aecia on *Pyrus Malus*, *P. spectabilis*, and *P. Toringo*, and telia on *Juniperus chinensis* and *J. chinensis* var. *procumbens*; *G. Idetae* Yamada ex K. Hara with pycnia and aecia on *Amelanchier asiatica* and telia on *Juniperus rigida*; *G. hemisphaericum* K. Hara with pycnia and aecia on *Pyrus Zumi* and telia on *Juniperus chinensis*; *G. Shiraianum* K. Hara with pycnia and aecia on *Pyrus sinensis* and telia on *Juniperus littoralis*. A synopsis and key are given of Japanese species of *Gymnosporangium*.—*H. R. Rosen*.

1194. VAN HOOK, J. M. Indiana fungi—V. Proc. Indiana Acad. Sci. 1920: 209-214. 1921.—The present paper consists of a list of 68 species of fungi collected in Indiana. Under those listed no attempt has been made to fully describe the species, but variations from original descriptions have been noted or descriptions extended in the following: *Daedalea extensa* Pk., *Ceratostomella barbirostris* (Duf.) Sacc., *C. echinella* E. & E., *Hypoxylon perforatum* (Schw.) Fr., *Phyllosticta Smilacis* E. & E., *Septoria albaniensis* Thuem., *Vermicularia Dematium* (Pers.) Fr. var. *microspora* n. var., *Cylindrosporium Scrophulariae* Sacc. & Ell., *C. Ulmicolum* E. & E., *Gloeosporium Betularum* Ell. & Mart., *Ramularia arvensis* Sacc.—*F. C. Anderson*.

1195. VAN HOOK, J. M. The pycnidium of *Cicinnobolus*. Proc. Indiana Acad. Sci. 1920: 215-216. Fig. 1-3. 1921.—While *Cicinnobolus* has been heretofore described for the most part as infecting only conidiophores, in the case of *Podospheera oxyacanthae* (DC.) de Bary it occurs apparently only on the perithecia, considerably altering their structure.—*J. M. Van Hook*.

1196. WINGE, Ø. Om nogle hyppigt forvekslede Rorhat-Arter. [On certain frequently confused *Boletus* species.] Meddelel. For. Svampekl. Fremme 2: 96-100. 1 fig. 1920.—A brief discussion is given of the characters and identity of 3 Danish species of *Boletus*: *B. aereus* Bull., *B. luridus* Schaeff., and *B. erythropus* Pers.—C. Ferdinandsen.

1197. WORMALD, H. Observations on a discomycete found on medlar fruits. Trans. British Mycol. Soc. 7: 287-293. Figs. 1-2. 1922.—A discomycete found on medlar fruits was found to differ only slightly from *Sclerotinia Mespili* and is believed to be the ascigerous stage of *Mespilus germanica*.—W. B. McDougall.

1198. ZELLER, S. M. Contributions to our knowledge of Oregon fungi—I. Mycologia 14: 173-199. 6 fig. 1922.—A list of 204 species, mostly Eubasidiomycetes, including the following: *Cyphella marginata* McAlpine, reported for the first time in this country on twigs of peach, apple, and almond; *Merulius pilosus* Burt sp. nov., a buff colored species possessing gloeocystidia; *Lepista pulcherrima* sp. nov., possessing a reddish colored pileus and a peronate stem; *Tricholoma subannulata* (Peck) comb. nov., described by Peck as an *Armillaria*; *Stropharia rugomarginata* Zeller & Epling sp. nov., with a reticulate-rugose margin of the pileus; *Scleroderma hypogaeum* sp. nov., possessing alveolate-reticulate spores; and *Gautieria Parksiana* Zeller & Dodge sp. nov.—H. R. Rosen.

LICHENS

1199. BURNHAM, STEWART H. Lichens of the Lake George region. Concluded. Bryologist 25: 72-80. 1922.—The scope of this series of articles has already been outlined [see. Bot. Absts. 11, Entries 4273-4274]. The present installment enumerates 107 species and varieties, with full data of collection. *Haematomma elatinum ochrophaeum* (Tuck.) Merr. & Burn., *Candelaria concolor effusa* (Tuck.) Merr. & Burn., *Parmelia tiliacea subquercifolia* (Hue) Merr. & Burn., *Caloplaca aurantiaca flavovirescens* (Wulf.) Burn., *C. cerina sideritis* (Tuck.) Merr. & Burn., *Physcia fusca detonsa* (Fr.) Burn., *P. orbicularis endococcinea* (Koerb.) Burn., and *Placynthium Petersii* (Tuck.) Burn. are proposed as new combinations.—E. B. Chamberlain.

1200. KNIGHT, H. H. Lichens of Haslemere district. Trans. British Mycol. Soc. 7: 225. 1922.—A list of 66 species of lichens collected near Haslemere, Surrey, during the spring foray of 1921, is given.—W. B. McDougall.

1201. LYNGE, BERNT. Studies on the lichen flora of Norway. Videnskabsselskab. Skrifter (Mat.-Nat. Kl.) 1921: 1-252. Pl. 1-13, fig. 1-5, 65 maps. 1921.—The author recounts the distribution of all non-crustaceous lichens in Norway (with the exception of the *Physcia*-ceae, with which the author has previously dealt [Videnskabsselskab. Skrifter (Mat.-Nat. Kl.) 1916]). Under each species is given a survey of its various subspecies, varieties, and forms belonging to the Norwegian flora, and the distribution of each separate form is represented as accurately as possible. Though the lichen flora of several parts of the country is still imperfectly known, the main features of distribution can be clearly shown in most cases. The new varieties described and new combinations of names established are: *Parmelia Bitteri* nom. nov. (*P. obscurata* Bitter, non Ach.), *P. Bitteri* var. *isidiata* nov. var., *P. Scortea* Ach. f. *borealis* Lynge, *P. fraudans* Nyl. f. *caesiopruinosa* f. n., *P. excrecens* (Arn.) var. *pilosella* comb. nov., *Cetraria lacunosa* f. *norvegica* f. n., *Alectoria samentosa* Ach. f. *sorediata* f. n. Critical remarks or amplified diagnoses are given in many cases. In the preface a brief survey of previous investigations on the lichen flora of Norway is given, and in 2 introductory chapters the author treats of the economic uses of the lichens in Norway and the general features of the distribution of the lichen flora of the country. He divides the species into 2 chief groups: those of the Coast Flora and those of the Inland Flora, each with several subdivisions. The distribution of 65 selected species is represented on the maps accompanying the paper. In an appendix KRISTIAN NISSEN has given a survey of the Lapponian lichen names.—Jens Holmboe.

1202. RUESS, JOHANN. *Die Einteilung der Cladonien.* [The classification of the Cladoniae.] Krypt. Forsch. Bayer. Bot. Ges. München 3: 164-166. 1918.—The author calls attention to the various methods of classification that have been proposed for the species of *Cladonia*, and emphasizes the difficulties of arranging the species of extensive areas in a single system. He therefore recommends classifications adapted to the species of restricted areas, and the method which he here suggests is based on the species of Germany. He divides them into 3 groups, as follows: "Grossblättrige" (large-leaved), referring to the primary thallus, with 4 species; "Kleinblättrige" (small-leaved), with 22 species; and "Krustenflechte" (crustaceous lichen), with 1 species.—A. W. Evans.

BACTERIA

1203. BROWNE, W. W. *Halophilic bacteria.* Proc. Soc. Exp. Biol. and Med. 19: 321-322. 1922.—The red coloration on salt fish is due to 2 organisms, *Spirochaeta halophila* producing a pale pink coloration and *Bacterium halophila* causing a transparent red. Optimum concentration of salt is saturation. The size, shape, and motility of the organisms is dependent upon the salt concentration. The optimum temperature is 50-55°C. Both forms tolerate indefinite exposure to brightest sunlight. They are present in solar evaporated salt. Sea salts from all over the world contain similar organisms.—D. S. Welch.

1204. HELLER, HILDA HEMPL. *Classification of the anaerobic bacteria.* Bot. Gaz. 73: 70-79. 1922.—The previously existing ideas regarding the mutability and stability of anaerobic bacteria are discussed. It is pointed out that if bacteria do not lack one of the best recognized attributes of living matter, they must possess the ability to mutate. Then it is necessary to determine where the mutations of bacteria lie, and what range of characters they cover before it can be determined what characters are stable enough for systematic purposes. It is suggested that the following general rules should be found convenient in classifying bacteria: (1) Strains which differ from each other in characters which are readily subject to mutation and that breed true, may be termed biotypes. (2) Strains which behave alike in those characters that fall within a genus and have not been found to mutate readily, may be grouped as species. (3) Organisms which show the same general reactions on ordinary media and that have the same general morphological habit, may be grouped in genera. The distinguishing characters of 2 sub-families and 1 family including all of the genera are given.—I. V. Shunk.

MYXOMYCETES

1205. SANDERSON, A. R. *Notes on Malayan Mycetozoa.* Trans. British Mycol. Soc. 7: 239-256. 1922.—This paper deals with myxomycetes collected in that part of the Malayan Peninsula which lies between north latitude 1° and 6° and east longitude 100° and 104°. Large tracts of virgin forest in this area have been cut down and the land cleared and set out to plantations of *Hevea brasiliensis* or of coconut. In collecting myxomycetes special attention was given to these plantations. About 70 species are listed, most of them with notes on habitats. Tables are given showing the months in which the various species were collected and the habitats in which they were found.—W. B. McDougall.

1206. SEAVER, F. J. [Rev of: MACBRIDE, T. H. *North American slime-moulds.* 299 p., 23 pl. Macmillan Co: New York, 1922 (see Bot. Absts. 11, Entry 3446).] Mycologia 14: 233-234. 1922.—"In matters of nomenclature the author has not followed hard and fast rules, but has apparently attempted to use the oldest recognizable specific names without regard to rule or date. . . . One other very commendable feature of the book is the extensive notes and observations which supplement the technical descriptions."—H. R. Rosen.

PALEOBOTANY AND EVOLUTIONARY HISTORY

E. W. BERRY, *Editor*

1207. BERRY, EDWARD W. Contributions to the paleobotany of Peru, Bolivia and Chile. Johns Hopkins Univ. Studies Geol. 4. 219 p., 25 pl., 9 fig. 1922.—This includes the following papers: (1) Carboniferous plants from Peru, the 1st descriptive account of plants of this age from South America. The flora includes: *Palmatopteris furcata*, *Eremopteris whitei*, *Eremopteris peruianus*, *Calamites suckowii*, *Calamostachys* sp., *Lepidodendron rimosum*, *L. obovatum*, *Lepidophyllum* sp., *Lepidostrobus* sp., *Stigmaria* sp., and *Knorria* sp. These occur at Paracas on the southern coast of Peru and indicate a former greater westward extent of the continent and a Westphalian age. (2) The Mesozoic flora of Peru, which contains a summary of the known Mesozoic plants of Peru, representing the genera *Equisetites*, *Taeniopteris*, *Ruffordia*, *Filicites*, *Cladophlebis*, *Sphenopteris*, *Weichselia*, *Klukia*, *Otozamites*, *Zamiostrobus*, *Cycadolepis*, *Podozamites*, *Thuites*, *Brachyphyllum*, and *Antholithus*. *Weichselia peruviana*, *Klukia zeilleri*, *Otozamites peruvianus*, *Otozamites zeilleri*, and *Thuites leptocladus* are described in detail. The age is considered as probably Portlandian. (3) the flora of the Concepcion-Arauco Coal Measures of Chile. This detailed geological and botanical discussion of the lower Miocene flora of the so-called Navidad beds of southern Chile includes 5 ferns representing *Gleicheniaceae*, *Cyatheaceae*, and *Polypodiaceae*; 4 gymnosperms, including *Zamia*, *Araucaria*, and *Sequoia*; 2 palms; and representatives of the following dicotyledonous families: *Piperaceae*, *Moraceae*, *Loranthaceae*, *Anonaceae*, *Myristicaceae*, *Caesalpiniaceae*, *Papilionaceae*, *Erythroxylaceae*, *Rutaceae*, *Meliaceae*, *Vochysaceae*, *Euphorbiaceae*, *Ilicaceae*, *Celastraceae*, *Sapindaceae*, *Tiliaceae*, *Bombacaceae*, *Dilleniaceae*, *Ochnaceae*, *Flacourtiaceae*, *Lauraceae*, *Combretaceae*, *Leechthidaceae*, *Myrtaceae*, *Myrsinaceae*, *Styracaceae*, *Apocynaceae*, *Borraginaceae*, and *Rubiaceae*. New species of *Cyathoides*, *Araucaria*, *Cassia*, *Triumfetta*, *Nectandra*, and *Goepertia* are described. This flora is distinctly Amazonian in character and its bearing on former climatic and geographic conditions and upon the time of uplift of the Andes is fully discussed. (4) Pliocene fossil plants from eastern Bolivia. This flora, found at an altitude of 11,800 feet, includes 3 ferns representing the *Gleicheniaceae* and *Polypodiaceae*; 2 monocotyledons, *Heliconia* and *Iriartites*; and dicotyledons representing the genera *Coussapoa*, *Pisonia*, *Anona*, *Cassia*, *Pithecolobium*, *Pilocarpus*, *Saccoglottis*, *Protium*, *Mespilodaphne*, *Myrica*, *Sideroxylon*, *Chrysophyllum*, and *Cedrela* or *Sapindus*. These are fully discussed in their geological and botanical aspects, and the conclusion is reached that the minimum amount of Andean uplift since this flora lived in this region is 6,500 feet. The following species are described as new: *Goniopteris cochabambensis*, *Filicites elaphoglossoides*, *Gleichenia pectinata fossilis*, *Heliconia tertiaria*, *Iriartites boliviensis*, *Coussapoa pliocenica*, *Pisonia pliocenica*, *Anona cochabambensis*, *Pithecolobium palcanum*, *Cassia pisllypampensis*, *Cassia coriacea*, *Cassia palcana*, *Pilocarpus bolivianus*, *Protium fossilium*, *Saccoglottis tertiaria*, *Mespilodaphne boliviana*, *Myrica pliocenica*, *Sideroxylon pliocenicum*, and *Chrysophyllum crassum*. (5) Late Tertiary plants from Jancocata, Bolivia. Characteristics and geological and climatic bearing of the following new species are discussed: *Pteris pacajensis*, *Phragmites* sp., *Alnus preacuminata*, *Osteomeles kozlowskiana*, *Polylepis tomentellifolia*, *Calliandra jancocatana*, *Cassia altoensis*, *Caesalpinia jancocatana*, and *Melastomites* sp.—E. W. Berry.

1208. BERRY, EDWARD W. Environmental interpretation of fossil plants. Pan Amer. Geol. 38: 9-17. 1922.—The author discusses criteria and methods of interpreting past physical environments by means of fossil plants.—E. W. Berry.

1209. CHANDLER, M. E. J. *Sequoia Couttsiae* Heer, at Hordle, Hants: a study of the characters which serve to distinguish *Sequoia* from *Athrotaxis*. Ann. Botany 36: 385-391. 5 fig. 1922.—A careful study of the differences between *Athrotaxis* and *Sequoia* was begun as a result of the discovery that material from the Lower Headon Beds at Hordle, England, which had been referred to *Athrotaxis* by Gardner, was really *Sequoia*. The differences between the 2 genera in leaves, cone-scales, and seeds are described, and it is stated that in all these structures the fossil agrees with *Sequoia*.—W. P. Thompson.

1210. COCKERELL, T. D. A. A new genus of fossil Liliaceae. Bull. Torrey Bot. Club 49: 211-213. Fig. 1. 1922.—The fossil material from Florissant, Colorado, which has passed as *Tmesipteris Alleni* (Lesq.) Hollick and which was referred to *Carpolithes* in 1913 by Cockerell, is now referred to *Brachyruscus* gen. nov.—P. A. Munz.

1211. DACHNOWSKI, ALFRED P. The correlation of time units and climatic changes in peat deposits of the United States and Europe. Proc. Nation. Acad. Sci. [U. S. A.] 8: 225-231. 1922.—Successive layers of different kinds of peat ("forest, fibrous sedge and reed, and colloidal") in postglacial deposits, both in the U. S. A. and in Europe, indicate the succession of different types of vegetation and therefore of different climatic conditions. The evidence from peat deposits combines with other geological evidence to indicate that well-marked stages, during and since the last Ice Age, were nearly simultaneous in northern America and northern Europe. From the combined evidence much may be inferred as to the chronology of these climatic and vegetational changes and of the stages of human culture associated therewith in Europe. A northward trend of civilization and agriculture seems to have continued for the last 60 centuries. Utilization of American peat lands should be facilitated by study of related European deposits.—Howard B. Frost.

1212. FRITEL, P. H. Contributions à l'étude du genre *Nipadites* Bowerbank et sur sa distribution géographique et stratigraphique. [Study of the genus *Nipadites* and its geographic and stratigraphic distribution.] Bull. Soc. Geol. France 21: 317-321. Pl. 16. 1922.—The author refers the genera *Castellinia* Massalongo 1852, *Fracastoria* Massalongo 1858, and *Palaeokeura* Massalongo 1854, described originally as many species of fossil fruits coming from the middle Eocene of Italy, to the palm genus *Nipadites*, and discusses the geographic and geologic range of this littoral genus.—E. W. Berry.

1213. HEMMER, A. Die fossile Flora des Oberen Ottweiler Schichten des Saarbeckens. [The fossil flora of the upper Ottweiler beds of the Saar basin.] Geog. Jahreshefte 1918/1919: 263-298. Pl. 6-10. 1920.—The author describes or comments on fossil plants found in the upper Ottweiler or Breitenbacher beds of the Saar basin. These comprise the uppermost Carboniferous of the basin and are probably of late Stephanian age. The genera mentioned and the number of species of each are as follows: 25 *Pecopteris* (1 new), 11 *Sphenopteris* (1 new), 2 *Diplotmema*, 3 *Odontopteris*, 7 *Alethopteris* (2 new), 2 *Callipteridium*, 1 *Callipteris*, 1 *Neuropteris*, 1 *Linopteris* (new), 1 *Aphlebia*, 5 *Sphenophyllum*, 2 *Calamites* (1 new), 2 *Annularia* (1 new), 3 *Asterophyllites*, 2 *Palaeostachya*, 1 *Macrostachya*, 1 *Equisetites*, 3 *Lepidostrobus*, 1 *Lepidophyllum*, 1 *Lepidophloios*, 3 *Sigillaria*, 1 *Sigillaristrobus*, 1 *Stigmara*, 1 *Pterophyllum*, 1 *Rhabdocarpus*, 1 *Trigonocarpus*, and 1 *Samaropsis*.—E. W. Berry.

1214. HOWE, MARSHALL A., and ARTHUR HOLLICK. A new American fossil hepatic. Bull. Torrey Bot. Club 49: 207-209. Fig. 1. 1922.—*Jungermanniopsis* gen. nov. and *J. Cockerellii* sp. nov. are published for a specimen from Miocene shale of Florissant, Colorado.—P. A. Munz.

1215. McLEAN, R. C. On the fossil genus *Sporocarpion*. Ann. Botany 36: 71-90. Pl. 8-10. 1922.—The author discusses the genus *Sporocarpion*, first described by Williamson, and elaborates and extends the evidence advanced in a paper published in 1912 for considering these remains to represent not plants, but a group of extinct radiolarian Protozoa, which became specialized for inhabiting the organically charged fresh and brackish waters of the Carboniferous lagoons.—E. W. Berry.

1216. RUEDEMANN, RUDOLPH. New forms of life from the Silurian. Proc. Nation. Acad. Sci. [U. S. A.] 8: 55-56. 1922.—Fossils recently obtained from the Bertie waterlime and the Lockport limestone of New York include the following: algae with air bladders, primitive land plants, and graptolites (*Dictyonema* and *Inocaulis*).—Howard B. Frost.

1217. SEWARD, A. C. On a collection of Carboniferous plants from Peru. *Quart. Jour. Geol. Soc. London* 78: 278-283. *Pl. 13, 1 fig.* 1922.—The author describes the following indefinite remains from Paracas, Peru, and suggests that they are lower Carboniferous in age *Sphenopteris* sp., *Lepidodendron* sp., *Sigillaria* or *Lepidodendron*, and *Bothrodendron* sp.—E. W. Berry.

1218. SEWARD, A. C., AND R. E. HOLTUM. Jurassic plants from Ceylon. *Quart. Jour. Geol. Soc. London* 78: 271-277. *Pl. 12.* 1922.—The paper records the following well known species from the lower Oolite (Jurassic) of Ceylon: *Cladophlebis reversa*, *C. denticulata*, *Taeniopteris spatulata*, *Araucarites cutchensis*, *Brachyphyllum mamillare*, *Elatocladus plana*, and *Desmophyllum* sp.—E. W. Berry.

1219. YABE, H. Notes on some Mesozoic plants from Japan, Korea and China, in the collection of the Institute of Geology and Paleontology of the Tôhoku Imperial University. *Sci. Rept. Tôhoku Imp. Univ.* 7: 1-28. *Pl. 1-4.* 1922.—The author describes the Permian forms. *Annulariopsis inopinata* Zeiller and *Sphenophyllum sincoreanum* n. sp. from beds in Korea regarded as lower Triassic in age, and the following forms from Mesozoic beds in China, Japan, and Korea: *Ruffordia goepperti*, *Cladophlebis browniana*, *C. geyleyana*, *C. lobifolia*, *C. denticulata*, *C. distans*, *C. nebbensis*, *C. argutula*, *C. haiburnensis*, *Pterophyllum inconstans*, *Clathropteris* c. f. *meniscoides*, *Zamiophyllum buchianum*, *Ctenis* (?) sp., *Ginkgo sibirica*, *Baiera* (?) *concinna*, *Phoenicopsis angustifolia media*, *Frenelopsis* c. f. *hohenneggeri*, and *Elatocladus manchuricus*.—E. W. Berry.

(See also in this issue Entries 939, 949, 972, 990, 998, 1014, 1015, 1025, 1028, 1031, 1032, 1033, 1042, 1079, 1081, 1085, 1112, 1124, 1136, 1137, 1138, 1142, 1143, 1144, 1146, 1153, 1154, 1156, 1158, 1162, 1165, 1167, 1168, 1180, 1185, 1188, 1192, 1193, 1197, 1198, 1393, 1403, 1406, 1419, 1422, 1492, 1496, 1499, 1503, 1504, 1525)

DISEASES CAUSED BY FUNGI

1220. ANONYMOUS. "Damping off" and "foot rot" of the tomato. *Exp. and Res. Sta. Nursery and Market Gard. Industries,—Development Soc., Ltd., Turner's Hill, Cheshunt, Herts Ann. Rept.* 7: 38-39. 1921.—A number of organisms are responsible, particularly *Phytophthora cryptogea* and *P. parasitica*. The disease organisms are transmitted through the soil, water, pots, and seed boxes. In addition to mentioning the heat and formaldehyde methods of soil sterilization, the author describes a preparation, Cheshunt Compound, which can be applied to the soil while the plants are growing. It controls the disease without injury to the plants. This preparation consists of finely powdered copper sulphate (2 ounces) and ammonium carbonate (11 ounces) mixed and stored in a sealed glass or stone jar 24 hours or longer. One ounce is then dissolved in a little hot water and water added to make 2 gallons. Promising results have also been obtained with this solution in the control of *Verticillium albo-atrum*, *Fusarium* sp., and *Rhizoctonia*.—W. H. Tisdale.

1221. ANONYMOUS. Leaf spot or anthracnose of cucumber. *Exp. and Res. Sta. Nursery and Market Gard. Industries,—Development Soc., Ltd., Turners' Hill, Cheshunt, Herts Ann. Rept.* 7: 32-38. 1921.—The life history of the causal organism, *Colletotrichum oligochaetum*, which attacks all parts of the host plant, is given, and the disease and the factors influencing its development under greenhouse conditions are described. Control measures include sanitation, disinfection, and cultural methods.—W. H. Tisdale.

1222. ANONYMOUS. New York observations on take-all. [Rev. of: KIRBY, R. S. The take-all disease of cereals and grasses. *Phytopathology* 12: 66-68. 1922 (see Bot. Absts. 11, Entry 4364).] *Agric. Gaz. New South Wales* 33: 566. 1922.

1223. AJREKAR, S. L., AND D. V. BAL. Observations on the wilt disease of cotton in the Central Provinces. *Agric. Jour. India* 16: 598-617. *Pl.* 33-34. 1921.—Two strains of a species of *Fusarium* were isolated from wilted cotton plants and their causal connection with the wilt disease established by inoculation experiments. Besides the usual *Cephalosporium* and *Fusarium* type of spores and chlamydospores, these 2 strains produce on culture media sclerotium- or perithecium-like bodies which differ in color. The reputed immunity of buri cotton was tested and confirmed. An attempt to ascertain whether the wilting of the cotton plant was due to any toxins secreted by the fungus gave negative results. The feasibility of different suggested methods of controlling the disease in the field is discussed in the light of the observations recorded.—A. Howard.

1224. BELGRAVE, W. N. C. Notes in the "South American leaf disease" of rubber. *Agric. Bull. Federated Malay States* 9: 179-183. 1921.—A review is given of published data on the disease of rubber attributed to *Fusicladium macrosporium* (Syn., *Passalora Heveae* and *Melanopsammopsis Ulei*), which attacks *Hevea brasiliensis*, *H. confusa* and *H. guyanensis*. A brief account of the author's observations and of the present position of the disease is appended.—I. H. Burkill.

1225. BARNUM, CLYDE C. Stem end rot of apples. *Science* 55: 707-708. 1922.—Apples have been found with decayed spots at and near the base of the stems. The fruit becomes covered with green spores, which were also found on the stems of fruit in cold storage. Cultures proved the mold to be *Penicillium expansum* Link., which ordinarily is thought to enter only through abrasions.—Inoculation experiments proved that this mold infects healthy apples and produces the same type of decay as was first found. The writer observes that such rot is rather common in California.—C. J. Lyon.

1226. BLAIR, R. J. Chemical woodpulp is attacked by molds. *Quebec Soc. Protection Plants Ann. Rept.* 14: 39-41. *Fig.* 1-3. 1922.—Small discolored spots are found in the sheets of chemical pulp, and if the discoloration spreads the product is worthless.—B. T. Dickson.

1227. BROWN, J. G. Cytospora canker, a disease destructive to cottonwoods and poplars. *Arizona Agric. Exp. Sta. Timely Hints for Farmers* 138. 4 p. 2 fig. 1922.—Of the Arizona cottonwoods and poplars, *Populus nigra* var. *italica* and *P. Fremontii* var. *Wislizeni* are least susceptible to attack by *Cytospora chrysosperma*. *Populus alba* var. *nivea* and *P. deltoides* are very susceptible. The canker also occurs on *P. MacDougalii*, *P. angustifolia*, *P. tremuloides*, *P. grandidentata*, and other species and varieties. Symptoms of the disease are given. Control measures advocated are selection of resistant varieties, good care, and pruning of diseased parts.—Herbert C. Hanson.

1228. BRUNER, STEPHEN C. Sobre la transmisión de la enfermedad del "mosaico" o "rayas amarillas" en la caña de azúcar. [Transmission of sugar cane "mosaic."] *Rev. Agric. Com. y Trab. [Cuba]* 5¹: 11-22. *Fig.* 1-5. 1922.—The studies of E. G. Smyth and of E. W. Brandes proving that the disease is transmitted by insects are discussed, and experiments to determine the possible role of the following insects in the transmission of the disease are recorded: *Kolla herbida* Walk. (*Tettigonia similis* Walk.), *Tettigonia* sp., *Draculacephala mollipes* Say., *D. reticulata* Sign., *Myndus crudus* Van D., *Stenocranus* (Delfax) *Saccharivorus* Westw., *Phaciocephalus* sp., *Oliarus* sp., *Monecphora bicincta* Say., *Pseudococcus calceolariae* Mask., *Pseudococcus sacchari* Ckl., *Aphis maydis* Fitch., *Sipha maydis* Pass., *Thrips*, *Tarsonemus spinipes* Hirst., *Paratetranychus viridis* Banks., *Euscelis bicolor* Van D., *Liburnia* sp., and *Aphis setariae*. Positive transmission of the disease was attributed only to *Aphis maydis* Fitch, in which case, however, only a low percentage of infections was obtained. Artificial

inoculation and transmission of the disease were effected by mechanical means, the disease appearing in 18 days. Various methods of artificial inoculation are discussed. Literature is cited.—G. R. Hoerner.

1229. BURLISON, W. L., AND R. W. STARK. Treating oats for smut. Illinois Agric. Exp. Sta. Circ. 240. 4 p. 1920.—Results are reported on the yield of oats (*Avena sativa*) and the percentage of smut (*Ustilago Avena*) present where seed was treated with varying quantities of formalin solution. During this experiment, which was conducted for 5 years, 1 pint of 40 per cent formaldehyde mixed with 10 gallons of water and used at the rate of 1 pint of solution per bushel of oats, gave satisfactory results.—O. H. Sears.

1230. DASTUR, J. F. Die-back of chillies (*Capsicum* spp.) in Bihar. Mem. Dept. Agric. India Bot. Ser. 11: 129-144. 2 pl. 1921.—The most serious disease of chillies (*Capsicum annuum* and *C. frutescens*) in Bihar is the die-back disease, which does considerable damage in September and October in years of continuous rain or high humidity. It spreads rapidly from field to field and in severe cases the plants are either completely killed or so badly affected that the yield is negligible. Cold weather checks the disease, the plants recovering and putting out healthy new growth. The disease is caused by a fungus, *Vermicularia Capsici* Syd., which infects the growing point or the flower bud most readily if the humidity is above 85. Control measures carried out in 1917 show that Burgundy mixture is useful in checking the disease.—A. Howard.

1231. DOIDGE, E. M. Wart disease of potatoes: *Synchytrium endobioticum*. Perc. Jour. Dept. Agric. Union South Africa 4: 447-451. Pl. 1-3. 1922.—The author describes this disease, which has been discovered for the 1st time in South Africa in the Impendhle Division, Natal. No substance experimentally applied to the soil has proved a remedy for wart. It is carried from place to place by infected seed and is spread locally by lack of care in the use of tools and chiefly by feeding diseased material to animals. Since 1919, 11 early varieties, 21 2nd early, and 31 main crop varieties have been confirmed as immune to the disease and by order of the Agricultural Board only these may be planted in infected areas in England.—L. Goldblatt.

1232. DOWSON, W. J. On the symptoms of wilting of Michaelmas daisies produced by a toxin secreted by a *Cephalosporium*. Trans. British Mycol. Soc. 7: 283-286. 1922.—The outward symptoms of the common wilt disease of Michaelmas daisies are, first a mottling of the leaves with pale patches, then a paling of the entire leaf, and finally a yellowing, shriveling, and drying of the leaf. The experiments described in this paper indicate that the mottling is due to a toxin secreted by the fungus, which causes the chloroplasts to migrate toward the ends of the palisade cells and gradually to disintegrate. The final bright yellow color of the leaves is due to the yellow masses of disintegrated chloroplasts in the ends of the palisade cells.—W. B. McDougall.

1233. DUFRENOY, JEAN. The occurrence of *Cronartium ribicola* in Europe. Phytopathology 12: 302-304. 1922.—*Cronartium ribicola* occurs to some extent all over Europe north of the Alps. Though frequently found in France, it is not generally considered a menace in the government forests where proper sanitation is practiced.—B. B. Higgins.

1234. EASTHAM, J. W. Black currant rust. Ann. Rept. British Columbia Fruit Growers Assoc. 32: 42-43. 1921.—A brief discussion is given of the economic importance of the discovery of *Cronartium ribicola* in the province and of the fruit growers' interests and responsibilities in the situation.—J. W. Eastham.

1235. EASTHAM, J. W. White-pine blister-rust in B. C. Agric. Journ. British Columbia 7: 29, 41, 57, 64. 1922.—This is a popular article dealing with the probable consequences of the extensive discovery of blister rust on cultivated *Ribes* in the Coast region of British Colum-

bia in the fall of 1921. Attention is drawn to the quarantine placed on this area, and the reasons for it are discussed.—*J. W. Eastham.*

1236. ELLIOTT, JOHN A. The *Ascochyta* blight of cotton. [Abstract.] *Phytopathology* 12: 250. 1922.

1237. FOËX, ETIENNE. Le *Schizophyllum commune stipité*. [Stiped *Schizophyllum commune*.] *Bull. Soc. Path. Vég. France* 9: 151-152. *Pl. 1.* 1922.—*Schizophyllum commune*, growing at first on acorns or chestnuts buried several centimeters under ground, forms a stipe which elongates so that the sporiferous receptacle may reach the light. However, the stipe which has thus begun to form on the buried acorn continues to elongate even after the acorn has been dug up and the fungus in consequence is exposed to the light.—*J. Dufrenoy.*

1238. HUNGERFORD, CHAS. W. The relation of soil moisture and soil temperature to bunt infection in wheat. *Phytopathology* 12: 337-352. *Fig. 1-5.* 1922.—For some years it has been known that in the Palouse region of Idaho and Washington spores of *Tilletia Tritici* (Bjerk.) Wint., blown from threshing machines, infect the fallow soil and the succeeding crop of wheat. Recent investigations have shown that such soil infestation also occurs in other wheat-growing regions of the Pacific Coast. Field observations and field and greenhouse experiments have shown that soil temperature and soil moisture at the time of seeding are important factors in seedling infection. Under controlled conditions in the greenhouse the highest percentage infection was obtained at temperatures of 9-12°C., and in soil containing 22 per cent moisture with a moisture equivalent of 20.7. It was also observed that bunt infection in the field was much more abundant when the grain was sown just after a rain.—*B. B. Higgins.*

1239. KULKARNI, G. S. Conditions influencing the distribution of grain smut (*Sphacelotheca Sorghi*) of jowar (*Sorghum*) in India. *Agric. Jour. India* 17: 159-162. 1922.—The spores of the fungus germinate best between 20 and 23°C. Above 37°C. very few germinate and 40°C. prevents germination altogether. The seeds of jowar, on the other hand, germinate most rapidly at 36-40°C. and more slowly as the temperature falls. As infection takes place in the seedling stage, there is likely to be a direct connection between the amount of infection and the temperature at sowing time. This was confirmed by direct experiments carried out at Poona, Pusa, and in Sind.—*A. Howard.*

1240. LACHAINE, O. W. Sclerotial disease of the potato. *Quebec Soc. Protection Plants Ann. Rept.* 14: 105-109. *Fig. 1-6.* 1922.—During 1921 in Restigouche County, Province of New Brunswick, a 4-acre field of potatoes was affected to the extent of 10 per cent, and 4 others from 1 to 2 per cent, with a wilt and stalk rot due to *Sclerotinia libertiana*.—*B. T. Dickson.*

1241. LÖHNIS, M. P. Onderzoek over *Phytophthora infestans* (Mont.) de By. op de aardappelplant. [Investigation of *Phytophthora infestans* on potato.] [English summary.] *Diss. Veenman: Wageningen, Holland, 1922.*—Plants (158) from infected tubers did not show infection in the field earlier than those from healthy seed. Sixty-seven infected tubers kept sprouting at 25-27°C. gave no diseased sprouts, while 240 sound tubers grown on ground that had never been in potatoes before showed blight on the same day as plants in other fields. Infection of the sprout from a diseased tuber is not the normal method of propagation from season to season.—Tubers may show the disease before the leaves are blighted.—The stage of development has no influence on the chance of contagion through neighboring plants.—In summer the fungus can not enter the tubers through the eyes, and chances of infection through the lenticels appear to be small. Artificial infections through small injuries in the skin are easily accomplished. The usual way of entrance into the tubers is through small injuries.—Of 142 plants in a field, only 1 tuber was inoculated, but infections occurred, though no spreading through the stolons to other tubers was observed.—In determining the length of time after which infection through a wound becomes impossible, it was found that wounds in young tubers

were much sooner immune to inoculation than those of ripe tubers. A correlation was found between the state of ripeness of the cork-cambium and the length of time after which no inoculations succeeded. No correlation exists with the rate of formation of wound-cork or with a distinct stage in its formation. The wound-cork does not appear to be the only factor that protects against infection.—The method of inoculating sterile blocks of raw potatoes in test-tubes in order to determine the degree of resistance of different varieties is not reliable, because blocks showing no outside growth of mycelium may be deeply infected within. The extension in the parenchyma was equal in tubers of 28 varieties. In inoculating young tubers of 39 varieties on the cork-cambium infections succeeded. Only Bravo is apparently highly resistant. Bravo tubers are highly resistant also in the field. No difference in thickness of skin or in the rate of wound-cork formation was found among different varieties. As *Phytophthora* may grow on white bean agar with 60 per cent sucrose, no connection appears to exist between osmotic pressure of the cell-sap and the growth of the fungus.—*J. Westerdijk*.

1242. MAJOR, T. G. An *Alternaria* disease of *Polypodium*. Quebec Soc. Protection Plants Ann. Rept. 14: 59-61. 1 fig. 1922.—Concentrically-zonated, brown lesions, generally occurring at the margins of fronds, were caused by an *Alternaria* with conidia averaging $13.6 \times 40.3 \mu$ and tentatively named *Alternaria Polypodii* n. sp. The disease was experimentally produced by spraying a spore suspension of this fungus on healthy, sterilized fronds.—*B. T. Dickson*.

1243. MANNS, T. F. Report of fungus diseases for 1920. Delaware State Bd. Agric. Bull. 10. 72-77. 1921.—Apple blotch (*Phyllosticta solitaria*) was severe on some early varieties. Apple scab (*Venturia pomi*) is difficult to control but the delayed dormant spray is helpful. Apple rust (*Gymnosporangium macropus*) was severe in 1 district. Root rot of apple from fire blight was less active in 1920 than in the blight years (1915-1917). Crown gall (*Bacterium tumefaciens*) on apple caused much loss.—Many unsprayed pear orchards were defoliated with leaf blight (*Entomosporium maculatum*), and *Septoria pyricola* was common. Corn root rot was common, causing 10-15 per cent injury.—Root rot of peas caused by *Pythium deBaryanum* is noted. Many cases of "sick soil" due to parasitic fungi are mentioned. Late blight of potatoes (*Phytophthora infestans*) caused 8 per cent of rot in field and storage.—*T. F. Manns*.

1244. MANUEL, H. L. Spraying for black spot of the vine. Agric. Gaz. New South Wales 33: 585-586. 1 fig. 1922.—Two spraying devices lined with lead for use in spraying sulphuric acid solutions are described.—*L. R. Waldron*.

1245. MIÉGE, M. Observations sur quelques maladies des plantes cultivées au Maroc, en 1911. [Observations on the diseases of crop plants in Morocco.] Bull. Soc. Path. Vég. France 9: 102-108. 1922.—Wheat was heavily rusted by *Puccinia glumarum* in 1921, *Triticum aurum*, *T. turgidum*, and *T. monococcum* suffering as much as *T. vulgare*. *Phytophthora infestans* infects potatoes at any time of the year, even those which are cropped at the beginning of June. *Plasmopara viticola* spreads as the vine culture extends. The occurrence of several other fungous diseases is noted.—*J. Dufrenoy*.

1246. MITRA, MANORANJAM. Morphology and parasitism of *Acrothecium Penniseti* n. sp. (a new disease of *Pennisetum typhoideum*). Mem. Dept. Agric. India Bot. Ser. 11: 57-74. Pl. 1-4 (pl. 1, col.), 1 fig. 1921.—This new disease was found on bajra (*Pennisetum typhoideum*) a crop which takes 4th place among Indian cereals, with an area of 13,320,000 acres. The ears, leaves, and leaf sheaths are attacked, with the formation of brown spots with yellow margin. The cause of the disease is a new species of fungus (*Acrothecium Penniseti*) which infects the host by way of the stomata, or by piercing the epidermis. The mycelium is both intra- and inter-cellular and is found in all parts of the infected plant. Conidiophores arise in clusters through the stomata and spores are borne apically in fascicles of 2-5. The fungus is cultivable on most artificial media but gives the highest development on wheat broth agar, potato juice

agar, nutrient glucose agar, and on French bean agar; the reaction is between + 5 and + 10 of Fuller's scale. Conidia and brown chlamydospores are both produced in culture. The parasitism of the fungus has been proved by numerous inoculations on leaves and ears. Cross inoculations on the male inflorescence of maize were successful, but those on *Sorghum* gave negative results.—A. Howard.

1247. NOWELL, W. A root disease of cacao in Trinidad. Bull. Dept. Agric. Trinidad and Tobago. 18: 178-199. 3 pl. 1919.—The writer discusses *Rosellinia* diseases with special attention to that of the cacao due to *Rosellinia Pepo*, though another species is believed to attack cacao in certain localities. The fungus and the appearance of diseased trees are described. The fungus attacks both bark and wood and in cacao plantations the original infection may be traced to forest stumps left to decay, subsequent infection spreading from tree to tree. All infected trees should be burned and all roots destroyed; the roots of adjacent trees should be isolated by trenches and the soil aerated and limed. Sulphur is also recommended as a fungicide, but to prevent increased acidity it should be accompanied or followed by lime.—Florence A. McCormick.

1248. PUTTERILL, V. A. Pear scab in the Western Province: experiments and facts relating to its control. Union South Africa Dept. Agric. Bull. 1922: 31 p., 12 pl., 4 fig. 1922.—An account is given of certain spraying experiments to control pear scab (*Venturia pirina* Aderh.) and on its occurrence in South Africa. The experiments of 1920-1921, though negative with regard to scab control, were of value in proving the necessity of controlling primary leaf infection. Those of 1921-1922 resulted in a control of leaf infection by the use of either Bordeaux mixture or of lime sulphur. The amount of diseased fruit varied from 2 per cent in sprayed trees to 59 per cent in unsprayed trees. Six sprayings were found necessary, the 4th to 6th applications being combined with arsenate of lead for the control of codling moth. The perithecial stage was found and some observations were made on the discharge of the ascospores.—E. M. Doidge.

1249. PUTTERILL, V. A. Plant diseases in the Western Province IV. Two diseases of the loquat. Jour. Dept. Agric. Union South Africa 4: 332-337. Fig. 1-7. 1922.—A description is given of the diseased fruit and leaves of the loquat (*Eriobotrya japonica*) attacked by *Fusicladium* or scab and by *Entomosporium* blight. Suggestions are offered for the control of these diseases. A common leaf blight of quince and pear doing much damage in South Africa is caused by a similar if not identical *Entomosporium*. A winter stage of this fungus (*Fabraea maculata* Atk.) is known to occur on old fallen leaves. So far as the author knows this stage has not been found on the loquat.—L. Goldblatt.

1250. PUTTERILL, V. A. Plant diseases in the Western Provinces V. The control of pear scab or "*Fusicladium*." Jour. Dept. Agric. Union South Africa 4: 430-431. Fig. 1-2. 1922.—This disease may be kept in check by spraying with Bordeaux mixture or lime sulphur at certain times. The writer mentions the discovery last September, of the winter or perithecial stage of the fungus for the 1st time in South Africa.—L. Goldblatt.

1251. RATHBUN, ANNIE E. Root rot of pine seedlings. Phytopathology 12: 213-220. Fig. 1. 1922.—In an attempt to determine the relation of various soil inhabiting fungi to root rot of coniferous seedlings, a number of inoculations were made on 4-6 months old seedlings of *Pinus resinosa* Ait. and *P. banksiana* Lamb. with cultures of *Pythium deBaryanum* Hesse, *Corticium vagum* B. & C., *Phomopsis juniperovora* Hahn, *Rheosporangium aphanidermatus* Edson, *Fusarium* spp., and *Botrytis* spp. The fungi were grown upon rice mush. A fragment of this medium containing the fungus was placed in contact with the roots of the seedlings. After 10 days the condition of the root system of each plant was recorded. Some rot occurred on the roots of non-inoculated check plants; but it was decidedly more severe on plants inoculated with *Corticium vagum*. All of the fungi used caused some increase in the amount of root rot.—B. B. Higgins.

1252. REED, GEORGE M., AND GEORGE H. DUNGAN. Flag smut and take all. Illinois Agric. Exp. Sta. Circ. 242. 4 p., 1 fig. 1920.—The appearance and control of flag smut (*Urocystis Triticis*) are discussed. Varieties resistant to this disease are recommended. Control of take-all (*Ophiobolus graminis*) lies in selecting the less susceptible varieties for seed.—O. H. Sears.

1253. RIDLER, W. F. F. The fungus present in *Pellia epiphylla* (L.) Corda. Ann. Botany 36: 193-207. Fig. 1-8. 1922.—A fungus is described which was found to occur in the thallus cells of *Pellia epiphylla*. Infection was found in all plants examined. These were collected in England and Belgium. In some cases the fungus was found in the cells of the sporophyte, pycnidia being produced in the capsule wall, calyptra, and involucre. The fungus was isolated and grown in pure culture and identified as a species of *Phoma*. The author was not able to reinoculate with the cultured fungus as no *Pellia* without the fungus has been found. Usually the diseased host was able to grow and reproduce in a normal manner. A review of the work of various authors on Musci infected by fungal mycelia is given.—W. P. Fraser.

1254. RIVIER, A. Observations sur le *Sclerotinia libertiana* Fuck. [On *S. libertiana*.] Bull. Soc. Path. Vég. France 9: 134-137. 1922.—Sclerotia of *Sclerotinia libertiana* were found on shoots of *Pyrethrum cineraraefolium* growing in wet ground near lettuce and cantaloupes. The fungus was successfully inoculated from diseased lettuce and cantaloupes to *Pyrethrum*, which had not been reported hitherto as host to this fungus.—J. Dufrenoy.

1255. ROBERTS, J. W. Apple scab and other diseases. Rept. Maryland Agric. Soc. 6: 168-175. 1921 [1922].—The control of apple scab in Maryland can be accomplished largely by proper sanitary measures in plowing under the fallen leaves. The Winesap, Stayman, and Delicious varieties are rather susceptible to scab whereas York Imperial is nearly immune. Peach leaf curl, pear spot, and cherry leaf spot have caused severe damage in Maryland, but can be controlled by proper spraying.—A. Lee Schrader.

1256. RORER, JAMES BIRCH. The fungous diseases of the avocado. Bull. Dept. Agric. Trinidad and Tobago 18: 132-133. 2 pl. 1919.—Anthracnose is given as the only serious disease of avocado. The fungus is identical with, or very closely related to, the anthracnose of the mango (*Gloeosporium mangiferae*) described in Bull. Dept. Agric. Trinidad and Tobago 14: 164. 1915.—A description of the trouble is given and spraying with Bordeaux mixture is recommended. *Diplodia cacaovicola* causes die-back of avocados as well as of cacao and rubber. It has not been proved that the fungus is able to penetrate uninjured shoots but it is thought probable that it gains entrance into very young tissues through wounds made by the anthracnose fungus. Bordeaux mixture is recommended for this disease.—Florence A. McCormick.

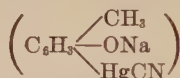

1257. RORER, JAMES BIRCH. The fungous diseases of roses and their treatment. Bull. Dept. Agric. Trinidad and Tobago 18: 29-31. 1 pl. 1919.—The following diseases are briefly described: black spot, caused by *Diplocarpon Rosae* Wolf (*Actinonema Rosae*); leaf spot, due to *Cercospora rosicola* Pass.; powdery mildew, caused by *Sphaerotheca pannosa* Lév.; red rust, due to the parasitic alga *Cephaleuros virescens*; and rose canker, caused by a species of *Stilbum*. For the first 3 troubles flowers of sulphur passing a 200-mesh sieve, and dry arsenate of lead,—1 pound to 9 of sulphur and thoroughly mixed,—are recommended. For the other 2 diseases cutting back and burning of the diseased stems is recommended and for the red rust spraying with Bordeaux is also advised.—Florence A. McCormick.

1258. RORER, JAMES BIRCH. The wither-tip of limes. Bull. Dept. Agric. Trinidad and Tobago 18: 1-3. 1 pl. 1919. [with notes added by W. G. FREEMAN].—A severe outbreak of wither-tip of limes, due to *Gloeosporium limetticolum* Clausen, is reported for July and August, 1918. The fungus attacks the tips and edges of very young leaves, the base of the stalk, or any point in the very young shoots. The first symptom is a somewhat water-soaked appearance of the attacked parts which later become brown and wither. Flowers and young fruits

are also susceptible. Infected flowers fall and diseased fruits show a rough scabby appearance and become cracked. During the dry season all dead wood and diseased leaves should be burned and as soon as the trees begin to make their new growth they should be sprayed with 4-4-50 Bordeaux mixture, to which has been added a sticker.—*Florence A. McCormick.*

1259. SANDERSON, A. R. On the parasitic habits of the plasmodium of *Physarum viride* var. *rigidum* Lister. Trans. British Mycol. Soc. 7: 299-300. 1922.—The plasmodium grows commonly in southern Malaya as a parasite on *Schizophyllum commune* on decaying logs of *Hevea brasiliensis*. Experiments showed that it can also grow as a parasite on *Hirneola hispida*.—*W. B. McDougall.*

1260. SCHAFFNIT, E. Zur Bekämpfung der Pilzkrankheiten des Getreidekorns. [Control of fungus diseases of grains.] Landw. Jahrb. 57: 259-283. 1922.—Copper sulphate and formaldehyde are commonly used for treating seed grain, especially wheat seed, for fungus spores (rust). When the concentration or time of action of these two active chemicals is not properly controlled, however, the embryos may be injured, in consequence of which the germination and growth are affected. But even if technical errors in the use of the chemicals are eliminated, the seed grain itself varies in sensitiveness due to varying degrees of ripeness of seed, injury in process of threshing, etc. A number of preparations were compared as to their disinfecting power. The most active of these were found to be Germisan

and Uspulun (a chlorphenol-mercury compound), the former being more active but having a somewhat retarding effect on seed germination. The following factors are also considered as bearing upon the causes of infection: (1) temperature of germination, (2) chemical condition of soil (lack or abundance of nutrients), (3) physical condition of soil (moisture content, soil structure), (4) change in life energy of seedlings (rapidity of growth of specific varieties, quality of seed).—*Selman A. Waksman.*

1261. SHAPOVALOV, M. *Rhizoctonia Solani* as a potato-tuber rot fungus. Phytopathology 12: 334-336. Pl. 23. 1922.—*Rhizoctonia Solani* Kühn has been found causing a jelly-like decay of the stem ends and knobs of potato tubers, principally of the Burbank and the Netted Gem varieties. In these varieties the elongated stem ends were found to be abnormal. The flesh was watery and translucent in appearance, and deficient in starch. A typical jelly-like rot was produced when such stem ends of disinfected tubers were inoculated with *Rhizoctonia*.—*B. B. Higgins.*

1262. SHARPLES, A. Treatment of mouldy rot disease by application of "agrisol." Agric. Bull. Federated Malay States 9: 184-191. 1921.—An account is given of a measure of success with this proprietary coal tar disinfectant against the mouldy rot disease of *Hevea brasiliensis*.—*I. H. Burkill.*

1263. SHAW, F. J. F. Studies in diseases of the jute plant. I. *Diplodia Corchori* Syd. Mem. Dept. Agric. India Bot. Ser. 11: 37-56. Pl. 1-11 (pl. 1, col). 1921.—The black band disease of jute (*Corchorus capsularis*) occurs towards the end of the season on the stems of the early sown crop raised for seed, and is widely diffused over the whole tract where this crop is cultivated in Bihar, Assam, and Bengal. The disease is caused by *Diplodia Corchori* Syd. which attacks the stems after flowering, the amount of infection varying greatly from season to season. The fungus is most severe on large, well-grown stems and infection takes place more readily upon green-stemmed than upon red-stemmed varieties. Further research is needed to ascertain the precise mode of infection, the limits of humidity and temperature under which infection takes place, and the reason why the late sown crop is resistant. Direct remedial measures are considered to be scarcely possible. The effective control of the disease must be

sought by means of increased knowledge of the factors involved in the growth of the host and the parasite. The fiber crop is generally free from the fungus.—A. Howard.

1264. SHERBAKOFF, C. D. *Fusaria* of corn. [Abstract.] *Phytopathology* 12: 251. 1922.

1265. SNAPP, OLIVER I. Dusting vs. spraying for the control of the curculio, brown rot and scab of peaches. [Abstract.] *Phytopathology* 12: 250-251. 1922.

1266. SPAULDING, PERLEY. Viability of telia of *Cronartium ribicola* in early winter. *Phytopathology* 12: 221-224. 1922.—Germination tests were made with teliospores of *C. ribicola* from leaves of *Ribes nigrum*, *R. odoratum*, *R. americanum*, *R. rotundifolium*, and *R. cynosbati*. The tests were made at Bethel, Vermont, beginning Sept. 26 and continuing until Dec. 8. Vigorous, living leaves bearing telia were collected from various localities. The viability of the spores was tested by placing the leaves bearing them in moist chambers and then, after a time, estimating the percentage germinated. Other telia-bearing leaves, both living and dead, were collected at various times during the period of the tests. Teliospores on leaves of *R. nigrum* germinated vigorously at the last test, Dec. 8. Strong germination was also obtained with spores on the leaves of *R. americanum* and *R. cynosbati*. On leaves of *R. cynosbati* which had fallen on the snow, teliospores had germinated Dec. 3. The results indicate that infection of pines may continue indefinitely into the winter under New England conditions.—B. B. Higgins.

1267. STOUTAMIRE, RALPH. Cause of melanose and kindred disease, stem-end rot. *Florida Grower* 26¹⁴: 6. 5 fig. 1922.—Melanose (*Phomopsis Citri*) on citrus is widely distributed throughout Florida. Bordeaux mixture (3-3-50) is probably the best spray. A new spray mixture, Bordeaux oil, has given splendid results; it seems to serve the double purpose of preventing melanose and stem-end rot, and scab.—J. C. Th. Uphof.

1268. TAUBENHAUS, J. J. Recent studies of Texas root rot of cotton. [Abstract.] *Phytopathology* 12: 250. 1922.

1269. TAYLOR, MINNIE W. Potential sporidia production per unit in *Cronartium ribicola*. *Phytopathology* 12: 298-300. Fig. 1. 1922.—The telial columns were counted on 68 leaves from the following species of *Ribes*: *R. americanum*, *R. cynosbati*, *R. glandulosum*, *R. lacustre*, *R. nigrum*, *R. odoratum*, *R. oxycanthoides*, *R. rotundifolium*, *R. setosum*, *R. triste*, and *R. vulgare*. The number of teliospores per column were then estimated and the number multiplied by the number of columns per leaf. Four times this product gave the maximum number of sporidia that could be produced per leaf. The comparisons were made on the basis of the potential sporidia per unit of leaf area. These comparisons indicate that the cultivated *R. nigrum* is by far the most dangerous neighbor to the pine trees.—B. B. Higgins.

1270. TOCHINAI, YOSHIHIKO. Studies on the physiology of *Fusarium* Lini. *Trans. Sapporo Nat. Hist. Soc.* 8: [14-19.] 1921.—*Fusarium* wilt of flax was first discovered in Japan by K. Miyabe in 1892. The disease is an important problem in Japan and in America. In Europe the centuries-old practice of crop rotation has reduced its ravages.—The fungus develops well and produces conidia on a variety of artificial media, and chlamydospores are formed in old cultures. In the synthetic medium used (ammonium nitrate, 10 gm.; potassium bisulphate, 5 gm.; magnesium sulphate crystals 2.5 gm.; cane sugar, 50 gm.; iron chloride, a trace; distilled water, 1000 cc.) tannic acid and citric acid retarded growth. In potato agar medium a low concentration of citric acid stimulated, while a high percentage retarded growth. In the synthetic solution the minimum, optimum, and maximum temperatures for growth are, respectively, 10-12, 30, and 36-37°C. Conidia do not germinate after 2 hours wet heat at 50°C. Wet heat of 60°C. does not kill the chlamydospores within 3 hours. The vitality of the fungus is not injured by -21°C.—Frederick V. Rand.

1271. VINCENS, F. *Maladies des jeunes plants et champignons microscopiques nouveaux observés sur Cinchona en Indochine.* [Seedling diseases and microscopic fungi on *Cinchona* in Indochina.] Bull. Soc. Path. Vég. France 9: 125-133. Fig. 1-4. 1922.—*Cinchona succirubra*, *C. ledgeriana*, and the hybrid *C. succirubra* × *C. ledgeriana* were diseased in nurseries at Honba, 4,500 feet above the sea in a very misty region of Indochina. The leaves of seedlings, chiefly those of *C. ledgeriana*, were spotted and fell early. Three species of *Phyllosticta* (*P. honbaensis* n. sp., *P. cinchonaecola* n. sp., and *P. Yersini* n. sp.), *Phlyctaena Cinchonae* n. sp., and *Phoma Cinchonae* n. sp. were found on fallen leaves, and are described. *Dendrophoma Cinchonae* n. sp., *Physalospora Cinchonae* n. sp., and *Guignardia Yersini* n. sp. occur on the cortex of diseased seedlings. Spraying with copper mixtures proved to be most dangerous to *Cinchona* seedlings, and the nursery had to be removed to a neighboring place.—J. Dufrenoy.

1272. WHITE, E. W. *Apple tree anthracnose or black-spot canker control.* Sci. Agric. 2: 186-191. Fig. 1-3. 1922.—The author recommends spraying early varieties with 3-4-40 Bordeaux mixture before the fall rains; spraying King and Jonathan in late August with 1-1½-40 Burgundy mixture, and when the fruit is picked with 3-4-40 Bordeaux mixture; and spraying late varieties with 3-4-40 Bordeaux mixture in August.—B. T. Dickson

1273. WILLAMAN, J. J., AND W. M. SANDSTROM. *Biochemistry of plant diseases III. Effect of Sclerotinia cinerea on plums.* Bot. Gaz. 73: 287-307. Fig. 1-7. 1922.—This is the 3rd paper in a series dealing with the biochemistry of the brown rot organism of stone fruits. The 1st dealt with its vitamine requirement, the 2nd with its relations to pectic compounds, and the present one with the changes which it produces in certain varieties of plums during the process of rotting. Five varieties of plums were used, 3 of which showed marked resistance to brown rot and 2 of which were very susceptible. Samples were taken (1) of half grown plums, (2) of plums just beginning to ripen, and (3) of fully ripe ones. Each sample was divided into 3 portions, one of which was analyzed immediately, another placed in a moist chamber and inoculated by injecting spores into the tissues, and the last left uninoculated in a moist chamber. The susceptible varieties showed a greater amount of sporulation on the surface of the fruits than the resistant ones; also, the juices of the former had a lower specific gravity, a lesser H-ion concentration, a higher titrable acidity, and a slightly smaller oxalic acid content. During the process of rotting the fungus causes a decrease in specific gravity, in H-ion concentration, and in titrable acid, but an increase in oxalic acid content. In addition it converts non-protein nitrogen of the host into protein nitrogen in its own vegetative parts and prevents the production of tannin as occurs in green fruits after picking.—F. A. Wolf.

DISEASES CAUSED BY BACTERIA

1274. ANONYMOUS. *Melon canker.* Exp. and Res. Sta. Nursery and Market Garden Industries'—Development Soc. Ltd.,—Turner's Hill, Cheshunt, Herts Ann. Rept. 7: 40. 1921.—A bacillus which is capable of producing this disease of melons (*Cucumis*) has been isolated from the cankers which appear on the plants at the ground line about the time the first fruits are set. Control measures consist of dusting diseased parts and adjacent soil with 2 parts by weight of powdered copper sulphate, 2 parts flowers of sulphur, and 10 parts dry slaked lime. Watering with Cheshunt Compound is also beneficial.—W. H. Tisdale

1275. ANONYMOUS. *Soft rot of the Arum.* Exp. and Res. Sta. Nursery and Market Garden Industries'—Development Soc. Ltd.,—Turner's Hill, Cheshunt, Herts Ann. Rept., 7: 39-40. 1921.—The Arum or Calla Lily (*Richardia*) is subject to a severe disease which at one time threatened to exterminate the crop. The disease is of a bacterial nature and is chiefly the result of a soft rot-producing organism, *Bacillus aroideae*. The disease is controlled satisfactorily by removing the diseased tissues from the corms, washing them thoroughly and steeping in 2 per cent formaldehyde for 4 hours. Clean soil and clean water should be used.—W. H. Tisdale.

1276. BROWN, D. D. Treatment of tobacco seed against wildfire and angular spot in southern Rhodesia. Rhodesia Agric. Jour. 19: 205-208. 1922.—The treatment of tobacco seed with a solution made up of 29.5 cc. of 40 per cent formaldehyde and 473 cc. of water is found to minimize the damage done to the tobacco crop by wildfire and angular spot caused respectively by *Bacterium tabacum* and *Bacterium angulatum*.—L. J. Goldblatt.

1277. DUFRÉNOY, J. Tumeurs de Sequoia sempervirens. [Tumors of Sequoia sempervirens.] Bull. Soc. Path. Vég. France 9: 148-150. Fig. 1-3. 1922.—Tumors may develop on wounded twigs, probably through infection. Transverse sections show polystelic structure, several vascular strands being imbedded in the hyperplased cortex-parenchyma, many cells of which are giant, multinuclear cells. Bacteria were observed in the parenchymatous cells.—J. Dufrénoy.

1278. EATON, B. J. Chemical notes. Malay. Agric. Jour. 10: 18-19. 1922.—Pink spot caused by *Bacillus prodigiosus* appears on the scrap rubber from *Hevea brasiliensis* on the day after it is brought into the factory.—I. H. Burkill.

1279. FROMME, F. D., AND S. A. WINGARD. Blackfire and wildfire of tobacco and their control. Virginia Agric. Exp. Sta. Bull. 228. 19 p., 2 pl. (col.), 9 fig. 1922.—This is a non-technical presentation of data covering 5 years' research which is recorded in detail in Virginia Agric. Exp. Sta. Tech. Bull. 25. Blackfire (*Bacterium angulatum*), which is also known as angular-leafspot, is more prevalent in Virginia than wildfire (*Bacterium tabacum*); the former was found in 85 per cent of fields in 1920 and the latter in 17 per cent. Reduction in yield caused by the 2 diseases during this year is estimated at 22 million pounds of tobacco. Both diseases occur on the leaves of seedlings in the plant bed as well as on leaves and flower parts of plants in the field, and field losses are determined in a large degree by prevalence of infection in the plant bed. Production of disease-free seedlings is considered the most important factor in control. This may be effected by selection of disease-free seed, disinfection of seed in mercuric chloride solution, disinfection of plant bed cloth or the use of new cloth, isolation of the plant bed and avoidance of disease-bearing material such as tobacco refuse or manure containing it. Satisfactory results have been obtained by a majority of the farmers who have practiced these measures. They should be supplemented by field sanitation, fall plowing of land when tobacco is grown in successive years, or rotation and avoidance of disease-bearing material and transfer of infection from field to field in working the crop.—F. D. Fromme.

1280. GARDNER, MAX W., AND JAMES B. KENDRICK. Tomato bacterial spot and seed disinfection. Indiana [Purdue] Agric. Exp. Sta. Bull. 251: 15 p., 10 fig. 1921.—The chief economic importance of this disease is due to the blackened scab-like spots on the fruit which are very objectionable to canners and market gardeners. No varieties have proved resistant. The bacteria which cause this disease (described elsewhere as *Bacterium exitiosum*, and by Miss E. M. Doidge as *Bacterium vesicatorium*) infect the leaves through the stomata. These bacteria are very resistant to drying, live over winter on the surface of the seed, and cause cotyledon infection at the time of germination. The disease is controlled by seed disinfection in mercuric chloride, 1:3000, for 5 minutes.—Max W. Gardner.

1281. HEDGES, FLORENCE. Bacterial pustule of soy bean. Science 56: 111-112. 1922.—This disease is much like that produced by *Bacterium glycineum* Coerper but differs in early stages. The organism has been named *Bacterium Phaseoli* var. *sojense* n. var. It occurs south of Washington. D. C.—C. J. Lyon.

1282. KILLIAN. Zur Anatomie des Kartoffelschorfes. [On the anatomy of potato scab.] Landw. Jahrb. 54: 267-276. Fig. 58-69. 1919.—The production of superficial and deep scab pustules or their various modifications seems to depend on the ability of the organ to develop protective layers which will exclude the pathogen. The cause for this different behavior of the cells of the infected tuber appears to be vested in the parasite. It is well known that the different Actinomycetes vary in sensitivity to the chemical reaction of the culture media.

It is also evident that the pathological metabolism of infected cells may cause the production of substances which reduce the vitality of the pathogen and permit the formation of protective periderm layers on the part of the host. A slow host response results in the formation of deep scab pustules, while a quick reaction permits only a superficial penetration by the parasite and the consequent development of superficial scab.—*Ernst Artschwager*.

1283. MACINNIS, JEAN. The origin of so-called "mildew" injury to paper-maker's felt. *Paper Trade Jour.* 74¹⁴: 41-42. *Fig. 1-3.* 1922.—No true "mildew" was found but injury to felts was caused by a bacterium close to *Bacillus mesentericus*. The bacteria form spores resistant to drying and high temperatures. The spores are nearly always present in felts and result in injury when moisture and temperature are favorable. Felts stored in a dry place at moderate temperatures are not damaged.—*H. N. Lee*.

1284. McLARTY, H. R. Fire blight. *Ann. Rept. British Columbia Fruit Growers Assoc.* 32: 47-50. 1921.—This is a popular address on the nature and control of fire-blight.—*J. W. Eastham*.

1285. MIÈGE, M. Sur une maladie de la pomme de terre observée au Maroc. A disease of the Irish potato in Morocco.] *Bull. Soc. Path. Vég. France* 9: 109-112. 1922.—The leaflets of potato, blackened toward their tips, later become detached and fall. Black dots appear scattered over the tubers and finally the diseased parts become liquefied and exude a clear liquid. A bacterium, isolated from diseased stalks, has been cultivated in pure culture. The disease appears to be of bacterial nature but preliminary inoculation tests gave conflicting results, possibly due to the presence of numerous aphids on the experimental plants.—*J. Dufrénoy*.

1286. SMITH, ERWIN F. Fasciation and prolepsis due to crown gall. *Phytopathology* 12: 265-270. *Pl. 16-20.* 1922.—A detailed account is given of the development of a fasciated shoot from a previously dormant bud of *Tropaeolum majus* L. after inoculation with *Bacterium tumefaciens* Sm. & T. No tumor tissue was evident on the surface of the fasciated shoot; but when sectioned and stained, proliferated tumor tissue was found in the interior of its base. The rest of the shoot was free from bacterial invasion. These results together with the study of other artificially produced fasciations have led to the suggestion that fasciations in general are due to some disturbance in the embryonic tissue of the growing point pushing apart the elements which develop into more or less separated axes of growth. Therefore, in studying individual cases of fasciation, the parasite or cause of the deformity should be sought at the base of the abnormal portion. In a discussion of prolepsis induced by the development of crown gall tumors the similarity to conditions found in certain plant diseases of obscure origin, such as peach "yellows," is pointed out.—*B. B. Higgins*.

1287. SMITH, CLAYTON O. Pathogenicity of the olive knot organism on hosts related to the olive. *Phytopathology* 12: 271-278. *Pl. 21-22.* 1922.—In order to obtain more definite data on the host range of *Pseudomonas savastanoi* E. F. S., inoculations were made on olive (*Olea europea* L.), *Frazinus velutina* Torr., *F. floribunda*, *Adelia acuminata* Michx., *Ligustrum ovalifolium* Hassk., *Chionanthus virginica* L., *Osmanthus fragrans* Lour., *O. aquifolium* Sieb., *Thevetia nereifolia* Juss., *Nerium oleander* L., *Coprosma Baueri* Endl., *Carissa grandiflora* DC., *Chrysanthemum frutescens* L., *Elacagnus angustifolia* L., *Vinca*, lilac, jasmine (probably *Jasminum primulinum* Hensl.) and on several species of *Prunus*. Definite knots were produced on the olive, *Frazinus velutina*, *F. floribunda*, *Adelia acuminata*, and *Jasminum primulinum*. On *Osmanthus aquifolium* and on *Chionanthus virginica* some hypertrophied tissue developed, but it was in the form of definite cankerous lesions rather than knots similar to those produced on the olive. On all other species the results were either negative or doubtful. The infectiousness of the organism seems to be confined to plants closely related to the olive.—*B. B. Higgins*.

1288. WELLES, COLIN G. **Bacterial plant diseases in the Philippine Islands.** *Science* 56: 18. 1922.—Tobacco and other solanaceous and non-solanaceous plants are attacked by *Bacterium Solanacearum* E. F. S. "Citrus is attacked by the citrus canker organism, cabbage by *Pseudomonas campestris* (Pamm.) E. F. S., cotton by *P. Malvacearum* E. F. S., and parsley by an organism not previously described." With the exception of citrus canker, all have been introduced.—C. J. Lyon.

1289. WELLES, COLIN G. **Identification of bacteria pathogenic to plants previously reported from the Philippine Islands.** *Philippine Jour. Sci.* 20: 279-285. 1922.—*Bacterium Solanacearum* E. F. S. on tobacco, *Pseudomonas Phaseoli* E. F. S. on *Phaseolus vulgaris*, and *Bacterium Malvacearum* E. F. S. on cotton are isolated and identified, while *Bacillus nelliae*, the causal organism of parsley wilt in the Philippines, is described as a new species. In the latter disease the bundles are packed with bacteria as in the wilt caused by *Bacterium Solanacearum*, and the whole behavior of parasitized plants is also similar. However, the author's physiological studies showed the organism to be entirely different and its description and cultural characters on various media are briefly given.—E. D. Merrill.

DISEASES CAUSED BY ANIMAL PARASITES (INSECTS, NEMAS, PROTOZOANS, ETC.)

1290. KULKARNI, G. S. **The "murda" disease of chilli (Capsicum).** *Agric. Jour. India* 17: 51-54. Pl. 6-7. 1922.—The disease is caused by mites and is said to be the greatest enemy of the chilli plant in Bombay. Good results were obtained by use of lime-sulphur wash.—A. Howard.

1291. MCCLINTOCK, J. A. **The control of root-knot. A progress report.** [Abstract.] *Phytopathology* 12: 250. 1922.

1292. WATSON, J. R. **Bunch velvet beans to control root-knot.** *Florida Agric. Exp. Sta. Bull.* 163. p. 53-59, fig. 11-12. 1922.—The method of controlling nematodes has grown out of summer fallow experiments. By fallowing and not allowing a crust to form on the surface of the ground, root-knot nematodes were greatly reduced.—For use in nematode control the bunch velvet bean has 2 advantages over the running beans: it allows constant cultivation, and its growing season is shorter. It is also practically immune to nematodes, which is not true of cowpeas, though the varieties Iron, Brabham, and Victory are highly resistant. Velvet beans should be planted early, after the last spring truck crop. If possible this should take place in May, and never later than June. Truckers are advised to employ this method during summer on land infected with root-knot.—J. C. Th. Uphof.

1293. WOODWORTH, H. E. **Injury to citrus by scale insects in the Philippines.** *Philippine Agric. Rev.* 14: 435-439. 1921.—From observations made principally in the various plantations of the College of Agriculture at Los Baños, Laguna, it is stated that the degree of primary injury from scale insects is usually directly related to the condition of the plant. Scale insects are most numerous during the dry season (January-July), when they receive the minimum of natural check. Injury at this time is greatly enhanced by the poor resistance of the trees during the dry season. Fungi parasitic on scale insects are most effective from August to January and insect parasites, from July to November. The principal fungus parasites of the scale, *Coccus viridis* Green, are *Microcera coccophila* Desm., *Aschersonia sclerotoides* P. Henn., and *Septobasidium* spp. Its most important insect parasites are *Coccophagus* sp. and *Aneristis* sp.—Spraying or fumigation is a necessary supplement to these natural checks.—Frederick V. Rand.

INFECTIOUS CHLOROSES (MOSAIC AND PEACH YELLOWS GROUPS, ETC.)

1294. ANONYMOUS. **Mosaic disease.** *Exp. and Res. Sta. Nursery and Market Garden Industries'—Development Soc. Ltd.,—Turner's Hill, Cheshunt, Herts Ann. Rept.* 7: 41. 1921.—Mosaic of tomato (*Lycopersicum esculentum* Mill.) is becoming one of the most important

diseases of the crop. Symptoms of the disease are discussed, and its spread by man and insects. Little is known about the disease.—*W. H. Tisdale.*

1295. DICKSON, B. T. **Studies concerning mosaic diseases.** Macdonald Coll. Tech. Bull. 2. 103 p., 8 pl. 1922.—A list of plants suffering from mosaic disease, complete to date of writing, is given. This includes as new, mosaic of *Rubus strigosus*, *Pisum sativum*, *Trifolium hybridum*, *T. incarnatum*, and *Medicago lupulina*. One instance of mosaic of *Medicago sativa* is noted. Symptoms are given, including striping of tobacco stems, mottling of tomato fruit, and speckling of red-purple blooms of sweet pea. Modifications of symptoms due to the temperature, and to the amount and virulence of the inoculum are discussed. Mosaic causes a reduction in set of seed and in germinating power in *Vicia faba*, *Trifolium pratense*, and *Pisum sativum*. Seed inheritance of mosaic occurs in clovers and apparently in Leguminosae generally, but not in raspberry. Studies of the pathological histology in 16 mosaic diseases indicate hypoplasia in lighter green areas, reduction in intercellular spaces and chlorophyll content, and increase in number of trichomes. In darker areas there is hypertrophy,—in severe cases due to hyperplasia,—increase in intercellular space volume and in chlorophyll content, and a reduction in number of trichomes. Degenerate plastids and "feverish" movement of minute bodies in severely affected cells is noted. Theories of etiology are given. The author could not find amoeboid bodies such as described in corn, sugar-cane, and *Hippeastrum*. Minute bodies, apparently similar to those described by Ivanowski, were found in diseased *Nicotiana tabacum*. Experiments to determine the effect of colored light indicated that no remedial result occurs. Cross-inoculations were carried out among the clovers *Trifolium repens*, *T. hybridum*, *T. incarnatum*, and *Medicago lupulina*; and *Macrosiphum pisi* Kalt was found to be a carrier of the disease. The symptoms distinguishing raspberry mosaic from curl are given. A bibliography gives 153 references.—*B. T. Dickson.*

1296. DUGGAR, B. M., AND JOANNE L. KARRER. **The sizes of the infective particles in the mosaic disease of tobacco.** Ann. Missouri Bot. Gard. 8: 343-356. 1921.—Too frequently our knowledge of the infective agency causing mosaic has been chiefly the assertion "of the passage of infective particles through some bacteriological filter, * * * with no particular effort to effect a more precise standardization" of the filters "so as to permit a more definite measurement of the particles concerned." The technique of experimentation has been divided into 3 phases: "(1) filtration of diseased juice through various ultra filters, (2) inoculation of healthy plants with the filtrates obtained, and (3) the standardization of the filters by a determination of their capacity to permit or prevent the passage of colloidal particles of known, or approximately known, sizes."—Preliminary tests were carried out by inoculation with filtrates from diseased juices after they had passed through (1) a Livingston atmometer cup, (2) layers of agar, and (3) Schleicher and Shiill parchment shells. Then such ultra filters as the following were utilized and standardized for size of the particles allowed to pass: (1) the Mandler diatomaceous filter, (2) spherical and cylindrical atmometer cups, (3) atmometer cups infiltrated with $Al(OH)_3$, (4) and celloidin cups. It was found in the preliminary tests that the spherical atmometer cups and the parchment shells allowed the passage of the infective agent. A smaller number of infective particles passed through the cylindrical atmometer cup than through the spherical one used. The Mandler filter proved to be rather porous.—In order to standardize the filters as to porosity, organic sols were used. Dextrin solutions, casein in milk free of fat, haemoglobin prepared from ox blood, and gelatin solution were selected as representing a wide range of sizes of particles. The results show that the infective particles are comparable in size to particles of hemoglobin. Assuming that at most haemoglobin particles have an average diameter of $30\ \mu\mu$ and the average small diameter of bacterial plant pathogens is around $1000\ \mu\mu$, we have 30:1000 to express roughly the diameter relations of mosaic disease particles in comparison with bacterial plant pathogens.—*S. M. Zeller.*

1297. ELMER, O. H. **Mosaic cross-inoculation and insect transmission studies.** Science 56: 370-372. 1922.—The mosaic diseases of the Cucurbitaceae, Solanaceae, and Leguminaceae are found to be inter-transmissible. Inoculations were made by means of transfer of juice

and by transfer of aphids from mosaic to healthy plants. The mealy bug, *Dactylopus* sp., also proved to be a good carrier of mosaic.—*C. J. Lyon.*

1298. ESMARCH, F. Beiträge zur Anatomie der gesunden und kranken Kartoffelpflanze. I. Anatomie der vegetativen Organe. [Contribution to the anatomy of the normal and diseased potato plant.] Landw. Jahrb. 54: 161-266. Fig. 1-57. 1919.—In the study of the anatomy of "leafroll plants" carried on for a number of years under the direction of Schander, considerable data bearing on the normal anatomy of the potato plant has been accumulated; and since, notwithstanding the pioneer researches of Sorauer and de Vries, there existed many gaps in our knowledge of the potato plant, it was found desirable to publish the fruits of the investigations of the Bromberg Institute, thereby putting our knowledge of the anatomy of the potato plant on a broader and more exact scientific basis. In this work both anatomical structure and ontogenetic development of all the organs are taken into consideration, and since the structure of many of the tissues is involved numerous illustrations have been added to the text. The literature references are very complete and full credit is given to the work of earlier investigators. According to the writer, the phloem of mature plants always becomes necrotic, and consequently regards the phloem necrosis theory of leafroll as obsolete.—*Ernst Artschwager.*

1299. GARDNER, MAX W., AND JAMES B. KENDRICK. Tomato mosaic. Indiana [Purdue] Agric. Exp. Sta. Bull. 261. 24 p., 13 fig. 1922.—A brief review of the literature on tomato mosaic is followed by an account of the nature and outstanding characteristics of the disease, including illustrations of the symptoms. Attention is focused chiefly upon the mode of overwintering of the disease in the related perennial weeds *Physalis subglabrata*, *P. heterophylla*, and *Solanum carolinense*, of which illustrations are included. These weeds are very abundant in the Indiana tomato regions and mosaic occurs very commonly among the weeds wherever tomatoes have been grown. This perennial reservoir of mosaic in the weed flora is increasing annually as new fields are used for tomatoes. As a mosaic control measure the eradication of these weeds in and near greenhouses, plant beds, and tomato fields is recommended.—*Max W. Gardner.*

1300. KASAI, MIKIO. Observations and experiments on the leafroll disease of the Irish-potato in Japan. Ber. Ohara Inst. Landw. Forsch. 2: 47-77. 1921.—The author discovered the disease in Japan in 1919. So serious has it become that growers in some provinces are obliged to import all their seed. The disease, which appears to be spreading, is characterized by rolling, rigidity, and discoloration of the leaves, dwarfing of the plant, discoloration of the tuber, shortness of stolons, persistence of diseased mother tubers, and marked reduction in crop yields. It is transmitted by the seed-tubers rather than through the soil, and may be carried from plant to plant by insects and by transfers of the juices of diseased plants. A bibliography is appended.—*H. S. Reed.*

1301. LEE, H. ATHERTON, AND E. W. KOPKE. Mosaic disease of sugar cane in the Philippines. Philippine Agric. Rev. 14: 418-421. Pl. 12-1 (pl. 12 colored). 1921.—A history and description of the disease are given, together with a discussion of present knowledge regarding it, losses due to its presence, and methods of control. Careful selection of cane points or cuttings and the utilization of resistant varieties are recommended.—*E. D. Merrill.*

1302. MARRE, EUGENE. La dégénérescence de la pomme de terre. Mission d'études en Hollande. [Degeneration in potatoes.] 52 p., 1 fig. Imprimerie Carrère: Rodez. 1921.—A detailed and circumstantial account is given of a French mission to Holland undertaken at the invitation of H. M. Quanjer for a first-hand study of the degeneration diseases of potatoes and the methods of control practiced in that country.—As a result of this survey certain recommendations are drawn up for the development and maintenance of disease-free seed, including (1) a search for healthy plants among different varieties, (2) isolated culture of selected plants, (3) multiplication by culture *en masse*, and (4) multiplication of selected strains and distribution to the growers.—*Frederick V. Rand.*

1303. MATSUMOTO, TAKASHI. Some experiments with Azuki-bean mosaic. *Phytopathology* 12: 295-297. *Fig. 1-2*. 1922.—A typical mosaic disease is reported as occurring on Azuki beans (*Phaseolus radiatus* var. *aurea*) in Japan. The diseased plants are more or less dwarfed. Their leaves are mottled with dark green and lighter yellowish areas, and are often somewhat distorted. In the dark green areas the palisade cells are much longer and narrower than in the normal leaf, while in the yellowish areas the corresponding cells are abnormally short and crowded. Similar conditions are also found in the spongy parenchyma. In the dark areas also the chloroplasts are larger and more abundant than in the lighter areas; and starch is more abundant in the dark areas irrespective of the time of day. Field observations indicate that some varieties may be immune to the disease.—*B. B. Higgins*.

1304. NELSON, RAY. Transference of the bean mosaic virus by *Macrosiphum solanifolii*. *Science* 56: 342-344. 1922.—The spread of bean mosaic was observed during 1921 under conditions which strongly suggested transfer by insects. The sudden appearance of the disease in the aphid-infested water cultures of beans growing in the greenhouse indicated even more definitely the mode of dissemination. Definite proof of the transfer of the virus by *Macrosiphum solanifolii* was obtained under controlled conditions, both in the greenhouse and in the field.—*Author's summary*.

1305. OORTWIJN BOTJES, J. Het gebruik van onrijpe aardappelknollen als pootgoed. [The use of unripe potato tubers for seed.] *Cultura* 34: 173-185. 1922.—The author states that theoretically tubers from early harvested plants, which are supposedly healthy, will give a smaller proportion of diseased descendants than tubers from late harvested plants. This is due to the presence of greater numbers of leaf aphids and "cicadas" during late summer and fall, which increases the chances for infection; and to the fact that in case of infection the contagium will not have the time to spread to as large a number of tubers per plant.—A number of examples are cited which seem to prove this hypothesis. A few (1788-1810) are mentioned in which it was apparently proved that plant material from northern regions and high altitudes was free from "curl" on account of freezing of the foliage before ripening of the tubers. Hutchinson at Wye, England, showed in 1912-1913 that "leafcurl" and "blight" in potatoes were very much decreased by the use of early harvested (July-Aug.) seed tubers. The same information came from Australia and many other places. In nearly all cases the yield was greatly increased. The author shows, however, that the number of cases was too small in which accurate account was kept of the diseased condition of parents and descendants. More experiments will have to be made. The author does not claim that disease-free seed potatoes may be obtained in this manner, but he believes that the influence of the so-called "degeneration" diseases can be greatly lessened.—*Peter J. Klaphaak*.

1306. PALM, B. T. De mozaiekziekte van de tabak een chlamydozoonose? [Is the mosaic disease of tobacco a chlamydozoonose?] *Bull. Deli-proef Sta. Medan, Sumatra* 15. 10 p. 1922. [English translation by P. G. WILSON.]—High lights in the history of tobacco mosaic investigation are briefly outlined from the time of Mayer's work in 1886 down to the more recent studies of Allard, Quanjer, and others.—In the author's histological and cytological investigations use was made of Flemming's mixtures, hot sublimate-alcohol, and Zenker's fluid as fixatives, while Heidenhain's haematoxylin, eosin, and Loeffler's methylene blue were employed as stains.—Using Deli tobacco affected with mosaic, it is claimed that both stained and unstained material showed minute granules of varying size, and peculiarly shaped corpuscles which were not present in healthy tobacco. The larger foreign corpuscles lay either in intimate contact with the nucleus or in its vicinity. They were often amoebiform, less frequently round to spherical. The cell nucleus in such cells was frequently hypertrophied and often showed signs of degeneration.—These granules and corpuscles are described in some detail and compared to the so-called "chlamydozoon-strongyloplasmas" in certain human and animal diseases, such as variola, molluscum contagiosum, trachoma, and "Geflügelpocke."—It is the author's opinion that a *Strongyloplasma* species must be considered as the cause of tobacco mosaic although definite proof of such a causative connection is not yet forthcoming.

It is proposed that the organism first discovered by Ivanowski, apparently identical with the author's findings, should be called in honor of this investigator *Strongyloplasma Ivanowskii* n. sp. A more detailed exposition is reserved for a later paper.—*Frederick V. Rand.*

1307. QUANJER, H. M. Een proef over de beteekenis van ziekten en ziekteverspreiding bij de pootgoedverwisseling, genomen door het Instituut voor Phytopathologie in 1920 en 1921. [An experiment on the significance of disease and disease distribution relative to changing of seed potatoes, conducted by the Institute for Phytopathology in 1920-1921.] *Cultura* 34: 135-141. 1922.—The deterioration of potato varieties in one area more than in another is caused mainly by the increase of certain diseases. The variety Paul Krüger shows a tendency toward susceptibility to leaf-roll while the variety Eigenheimer shows a similar tendency toward mosaic. The former was tested in different sections of the Netherlands. In an experiment near Oostwold, potatoes were planted in a beet field; aphids were rare and healthy plants were in the majority. In the plot near Bennekom aphids were observed, and many plants showed signs of disease. Other similar examples are given.—In connection with these experiments various suggestions are given relative to: (1) the disease distributing insects; (2) the kind of inter-crops; and (3) the influence of soil and climate upon insects and plant diseases. These experiments are to be widely continued.—*J. C. Th. Uphof.*

1308. RANKIN, W. H., AND J. F. HOCKEY. Mosaic and leaf curl (yellows) of the cultivated red raspberry. *Phytopathology* 12: 253-264. 1922.—The symptoms of leaf curl are very characteristic and unmistakable. The mid-vein of each leaflet in all new growth develops unequal tensions which cause it to arch upward and the tip of the leaflet to curl downward. A similar tension in the lateral veins often causes the entire margin of the leaflet to roll downward. The intravascular tissue is often "puckered" or "gathered." Leaves formed previous to infection remain normal throughout the season. New canes formed the year after infection has occurred are stunted and show a distinct phloem necrosis. Fruit formed on infected plants is insipid and has very little pulp. In many respects raspberry leaf curl suggests potato leaf roll. The symptoms of mosaic are not so constant or characteristic. On plants that have been diseased 3-4 years the new canes are short and very slender and the leaves are small, yellowish, and more or less mottled. On plants more recently infected these symptoms are less marked. The fruit produced is similar to that produced on plants affected with leaf curl. Both diseases seem to be spread by an aphid (*Aphis rubiphila* Patch). In the climate of St. Catharines, Canada, the spread is rather slow, usually limited to 1-2 adjacent plants each year.—*B. B. Higgins.*

1313. TICE, C. Mosaic disease of potatoes. *Agric. Jour. British Columbia* 7: 77, 83. 1 fig. 1922.—This is a popular article for potato growers.—*J. W. Eastham.*

PARASITIC PHANEROGAMS

1314. FISCHER, C. E. C. Host plants of *Santalum album*. Indian Forest. 48: 113. 1922.—Ten plants not usually recorded are given as hosts.—E. N. Munns.

1315. LUTHRA, JAI CHAND. *Striga* as a root parasite of sugarcane. Agric. Jour. India 16: 519-523. Pl. 24-26. 1921.—Two species of *Striga* (*S. densiflora* Benth. and *S. euphrasioides* Benth.) were found as semi-parasites on sugar cane in the low-lying areas along the River Sutlej in the District of Ludhiana. The haustoria of this parasitic phanerogam are 1-3 mm. in diameter and attached to the roots of cane in large numbers. The haustoria develop suckers which rupture the endodermis and penetrate into the vascular tissue.—A. Howard.

NON-PARASITIC DISEASES

1316. LUTMAN, B. F. The relation of the water pores and stomata of the potato leaf to the early stages and advance of tipburn. Phytopathology 12: 305-333. Fig. 1-15. 1922.—The tipburn of potato discussed in this paper is distinct from the burn produced by the potato leafhopper. It is entirely physiological in its origin, being brought about by excessive loss of water and the action of sunlight during periods of dry weather and brilliant sunshine; it is most abundant in Vermont about Aug. 10 when but few leafhoppers are present. The potato leaflets are provided with hydathodes, especially numerous near the tip, which open directly into a comparatively large vein running near the margin of the leaflet. During hot dry weather the loss of water from these hydathodes is so rapid that the conducting system of the leaf can not replace it, and the cells of the underlying tissues are plasmolized beyond recovery. This occurs most frequently at the tip of the leaflet where the hydathodes are so abundant. The subsequent advance of tipburn is due partly to plasmolysis of the cells and partly to the destructive action of intense sunlight on the chlorophyll. The severity of tipburn is reduced by spraying the plants with Bordeaux mixture, doubtless because water pores and stomata become clogged by the gelatinous colloids of the spray, with consequent reduction in transpiration.—B. B. Higgins.

DISEASES OF UNKNOWN CAUSE

1317. LEE, H. ATHERTON, COLIN G. WELLES, AND MARIANO G. MEDALLA. Fiji disease of sugar cane in the Philippines. Philippine Agric. Rev. 14: 413-417. Pl. 9-11. 1921.—This paper gives a general history and description of the disease, losses due to it, and methods of reducing those losses. Careful selection of cane points or cuttings, and the use of resistant or partly resistant varieties are recommended.—E. D. Merrill.

1318. SANDERSON, A. R., AND H. SUTCLIFFE. Brown bast. An investigation into its causes and methods of treatment. 71 p., 26 pl. (3 colored), 8 fig. Rubber Growers' Assoc.: London, 1921.—This investigational report takes up in detail the symptoms of brown bast of rubber tree, the effects of tapping, the distribution of brown bast cortex in affected trees, the incidence of burr formation, and experiments and recommendations relative to treatment.—Among the points brought out are the following: No case of brown bast has been observed in an untapped tree. If the depth of tapping has to be increased in order to obtain latex this disease may be suspected. The constant characteristic of brown bast is the abnormal presence in the latex of meristematic tissue which is almost invariably in the vicinity of latex vessels. The latex in these vessels is usually coagulated. Tapping is considered the prime cause of the disease and any tree subjected to tapping is liable to, although it does not necessarily develop, the disease. An increase in the period between tapping operations tends to reduce the number of cases. Stripping is a cure for brown bast, prevents its spread, and enables the tapping operations to be kept near the base of the tree where the richest reserve of latex is obtained.—Except in cases of deep-seated origin, starch is usually nearly or quite absent in brown bast cortex. Oil globules are frequently present and sometimes in considerable numbers. A brown substance resembling tannin is abundant, sometimes entirely filling many

of the cortex cells. The newly formed tissue arising from abnormal meristematic cells of the cortex sometimes becomes liquefied.—“The time is rapidly approaching when Brown Bast treatment will become part of the ordinary routine work of the estate.”—*Frederick V. Rand.*

GENERAL AND MISCELLANEOUS PATHOLOGICAL LITERATURE

1319. ANONYMOUS. Plant pathology. The Lancet 203: 85-86. 1922.—A brief discussion is given of the relationship between plant and animal pathology, especially the technique used in these fields by investigators. Closer cooperation in the 2 fields is suggested.—*W. H. Tisdale.*

1320. APPEL. Die Organisation des Pflanzenschutzes im deutschen Reich. [The organization of plant protection in Germany.] Arbeit. Deutsch. Landw. Ges. 314. 119-136. Fig. 1-2. 1921.—The author divides the growth of this work into 3 periods, the present being the 3rd. The organization of the work with main stations, substations, etc., is described in detail. There are 2 figures, in 1 of which the organization is shown as a grape vine with stem representing the “Direktion” and leaves the outlying stations or lines of work. The other figure is a map of Germany showing the locations of the stations.—*A. J. Pieters.*

1321. APPEL. Die wirtschaftliche Bedeutung der Pflanzenkrankheiten und die Mittel zu ihrer Bekämpfung. [The economic significance of plant diseases and means for their control.] Arbeit. Deutsch. Landw. Ges. 314. 101-118. 1921.—The author quotes figures to illustrate the serious economic loss due to plant diseases and insects, and the methods of combating them.—*A. J. Pieters.*

1322. BALL, E. D. Insects as disseminators of plant diseases. II. Systematic relations of carriers. Phytopathology 12: 229-231. 1922.—A survey of previous work indicates that an insect carrying the infectious entity of a plant disease over winter is very likely to be one which passes the winter in the adult stage; and that, in case of specific transmission, it is likely to be a sucking insect and to have a long adult life period.—*B. B. Higgins.*

1324. BIRD, MAURICE. Concerning yield deterioration in the older sugar countries. Internat. Sugar Jour. 24: 406-407. 1922.—As consulting chemist in British Guiana, the writer has observed that in many of the old plantations the plant food in the soil is less than is required by the growing cane. The crop is diminished and subject to insect and fungous pests, in particular to root rot (*Marasmius*). Application of artificial manure which supplied the lacking plant food not only increased the crop but freed it from *Marasmius*.—*C. Rumbold.*

1325. BISBY, G. R., E. E. CLAYTON, W. H. MARTIN, J. T. ROSA, JR., and E. A. STOKDYK. The cooperative potato spraying project: Report for 1921. Phytopathology 12: 241-248. 1922.—The report includes data from potato spraying experiments conducted by pathologists in British Columbia, Manitoba, Eastern Canada, Ohio, New Jersey, Missouri, Kansas, Pennsylvania, West Virginia, Kentucky, Indiana, and Arizona. In the states of Kansas and Missouri the value of Bordeaux mixture is questionable. Comparisons of dusting and spraying were made during 1921 in New Jersey, Ohio, and Manitoba; the results indicate the inferiority of dusting.—*B. B. Higgins.*

1326. BLAIR, R. J. The cause and prevention of decay in structural timber. Paper Trade Jour. 73²⁵: 51-53. Fig. 1-6. 1921.—A description is given of the causes of decay, especially in mill roofs, and the type of construction necessary to prevent decay.—*H. N. Lee.*

1327. BROWN, J. G. Treatment of seed potatoes for scab and black scurf. Arizona Agric. Exp. Sta. Timely Hints for Farmers 136. 4 p., 1 fig. 1922.—Popular descriptions of the mercuric chloride and formaldehyde treatments are given.—*Herbert C. Hanson.*

1328. BUCHNER, PAUL. Tier und Pflanze in intrazellulärer Symbiose. [Animal and plant in intracellular symbiosis.] 462 p. 2 pl., 103 fig. Gebrüder Borntraeger: Berlin, 1921.—This rather exhaustive, largely zoological work is divided into 7 parts dealing with (1) symbiosis of protozoa, sponges, and coelenterates with green algae and yellow algae; (2) symbiosis in worms; (3) in bryozoa, echinoderms, mollusks, and tunicates; (4) intracellular symbiosis in insects; (5) light symbiosis; (6) the errors in symbiosis investigation; and (7) concluding observations.—Of special interest to pathologists are the sections dealing with the presence of bacteria in amoebae and in *Cyclostoma elegans*, the presence of fungi (Chytridiaceae) in certain ascidians, the errors in symbiosis investigation, and general considerations relative to infection relations and the intimacy of symbiosis.—Nineteen pages are devoted to a literature list.—Frederick V. Rand.

1329. BUTLER, O., AND T. O. SMITH. On the use of acetates of copper as fungicides. Phytopathology 12: 279-289. Fig. 1. 1922.—The adhesive power and the fungicidal value of neutral and of basic copper acetate have been studied. Decomposition, which increases the adhesiveness of solutions of these salts, is much more rapid with the basic than with the neutral salt. The adhesiveness of both solutions is increased markedly by the addition of gelatin; and it should always be added, especially to the neutral solution. No measurable difference in the toxicity of the 2 was found; therefore, when obtainable, the basic salt is recommended. Either neutral or basic copper acetate might well replace cupra-ammonia as a spray, being cheaper and less injurious to foliage. Directions for preparing the sprays are given.—B. B. Higgins.

1330. CAESAR, L. Insect[s] as disseminators of plant diseases. III. Control problems. Phytopathology 12: 231-233. 1922.—The need of further study on the life history of causal organisms and of more definite knowledge as to the host relationships is emphasized. In many cases, such as mosaic diseases, there are doubtless many wild hosts that carry the infection throughout the winter. Better methods of insect control are also needed.—B. B. Higgins.

1331. CORY, E. N. Report of dusting and spraying investigations. Rept. Maryland Agric. Soc. 5: 318-327. 1920 [1921].—This report summarizes the recent results of dusting and spraying, and presents the results of dusting peaches, strawberries, and truck crops in Maryland. Dusting with 60 per cent sulphur—40 per cent lime controlled the peach lecanium (*Lecanium nigrofasciatum* Perg.). Dusting of strawberries proved successful, and dusting of truck crops offers great promise.—A. Lee Schrader.

1332. DICKSON, B. T. Diseases of the potato. Sci. Agric. 2: 202-206. Fig. 10. 1922.—This paper (one of a series) deals with potato canker, leak, and late blight.—B. T. Dickson.

1333. DICKSON, B. T. Diseases of the potato. Sci. Agric. 2: 234-236. 1922.—Sclerotinia wilt of potato occurred in Restigouche County, New Brunswick, during 1921. This disease, and the dry stem-rot and black scurf caused by *Rhizoetonia*, are both briefly discussed.—B. T. Dickson.

1334. DICKSON, B. T. Diseases of the potato. Sci. Agric. 2: 310-312. 1922.—This paper deals with early blight, wilt or fusariose, common scab, and silver scurf.—B. T. Dickson.

1335. DICKSON, B. T. Diseases of the potato. Sci. Agric. 2: 325-327. Fig. 13-14. 1922.—Black dot disease, caused by *Vermicularia varians*, is described for the 1st time from America. The 1st symptom is a slight yellowing of the foliage beginning at the tips of the leaflets and gradually involving the whole leaves, which finally become brown and withered. Under moist conditions, minute black sclerotia develop on the surface of the leaves and both inside and outside the lower part of the stems.—Potato dry rots and net necrosis are also briefly described.—Frederick V. Rand.

1336. DICKSON, B. T. Diseases of the potato. *Sci. Agric.* 2: 417-419. 1922.—This concluding section of the series briefly discusses black heart, frost necrosis, net necrosis, internal brown spot, spindling sprout, hollow heart, and arsenical injury under the general heading, Physiological Diseases. The paper concludes with general considerations on potato disease control.—*Frederick V. Rand.*

1337. DICKSON, B. T. Diseases of the potato. *Quebec Soc. Protection Plants Ann. Rept.* 14: 67-105. *Fig. 1-12.* 1922.—This paper brings together in one place the series concluded in the preceding entry. Some 25 potato diseases are classified under 8 groups according to type of cause and the salient known facts concerning each are briefly discussed.—*Frederick V. Rand.*

1338. DICKSON, B. T. Plant diseases of 1921 in Quebec. *Quebec Soc. Protection Plants Ann. Rept.* 14: 52-58. *Fig. 1-8.* 1922.—A brief account is given of some 20 commonly occurring diseases. The year 1921 in Quebec was typically a year of *Fusarium* root-rots and of mosaics.—*B. T. Dickson.*

1339. FAULL, J. H. Forest pathology in relation to forest conservation. *Quebec Soc. Protection Plants Ann. Rept.* 14: 14-22. *Fig. 1-5.* 1922.—This is an account of an invitation address given before the Society. Needle blight of white pine, heart rot of birch, butt and heart rots of balsam, etc., are discussed.—*B. T. Dickson.*

1340. FISHER, D. F. Spoilage of apples after harvest. *Ann. Rept. British Columbia Fruit Growers Assoc.* 32: 51-56. 1921.—Blue mold rot due to *Penicillium expansum* is the most important storage rot. Control consists mainly in avoidance of mechanical injury and sanitation of the packing house. Cooling to 32°F. reduces infection but does not effectively check progress of the disease where infection has already taken place. Scald is largely due to abnormal respiratory conditions resulting from poor aeration. Immature apples are more susceptible than those picked at maturity. Constant air movement, especially during the earlier period of storage, prevents or reduces it. Although humidity and carbon dioxide are proved not to be the cause, probably some gaseous excretion is responsible. The use of a small quantity of certain mineral oils of the "liquid petrolatum" type on the wrapping paper promises the best means of control, some of these giving complete control under the most unfavorable storage conditions. The minimum quantity of oil effective, as well as the best kind, has still to be determined.—*J. W. Eastham.*

1341. GARDNER, MAX W. Insects as disseminators of plant diseases. IV. Urgent problems of the future. *Phytopathology* 12: 233-240. 1922.—From the standpoint of economic importance and scientific interest, the most important problems in relation to insect-disseminated diseases are connected with the so-called virus diseases of the mosaic type. Some of the problems enumerated are: the nature of the mosaic contagion, infective principle, or virus; the host range of each virus with special reference to wild carriers of infection; the physiology of infection; transmission by means other than insects; the development of disease-resistant varieties; a better understanding of the life history and longevity of insects known to transmit the disease; the method by which diseases are carried and transmitted by insects; and more exact knowledge as to the species of insects capable of disseminating diseases.—*B. B. Higgins.*

1342. GARDNER, WRIGHT A. Notes on the physiology of the sweet potato. [Abstract.] *Phytopathology* 12: 251. 1922.

1343. GREAT BRITAIN MINISTRY OF AGRICULTURE AND FISHERIES. Collected leaflets on fungus pests of fruit trees. Sectional Vol. I. 60p., 21 pl. London, 1921.—An introduction by A. D. COTTON discusses the nature of fungi and modes of attack, methods of control and of cultivation and use of resistant varieties. Then follow the "collected leaflets" which take up

in turn some of the leading facts regarding the following diseases and their control: apple canker (*Nectria galligena*); apple and pear scab (*Venturia inaequalis* and *V. pirina*); apple mildew (*Podosphaeria leucotricha* Salm.); brown rot of apples (*Monilia fructigena* Pers.); blossom wilt of apples (*Monilia cinerea* forma *Mali*); crown gall (*Bacterium tumefaciens*); silver leaf in fruit trees (*Stereum purpureum*); wither-tip and brown-rot of plums (*Monilia cinerea* forma *Pruni*); die-back of fruit trees (*Cytospora leucostoma*); peach leaf-curl (*Eoasacus deformans*); American gooseberry mildew (*Sphaerotheca mors-uvae* Berk.); European gooseberry mildew (*Microsphaera Grossulariae* Lév); coral spot (*Nectria cinnabarina*); die-back of gooseberries (*Botrytis cinerea*); powdery mildew of the vine (*Uncinula necator* Burr.); and "reversion" or "nettlehead" of black currants. To this is added a list of 23 diseases of fruits not here discussed.—*Frederick V. Rand.*

1344. GREAT BRITAIN MINISTRY OF AGRICULTURE AND FISHERIES. Collected leaflets on cultivation and diseases of potatoes. Sectional Vol. III. ii + 69 p., 15 pl. (2 colored), 8 fig. London, 1921.—An introduction briefly outlines the history of the potato and adds a general statement concerning the diseases of this crop. The first three sections deal with the growing of the crop, and with the selection, storage, and treatment of the seed tubers. The remainder of the booklet discusses in turn the salient points regarding specific diseases and their control. The following diseases are taken up in some detail: blight (*Phytophthora infestans*); wart (*Synchytrium endobioticum*); powdery scab (*Spongospora subterranea* Lagerh.); blackleg (*Bacillus atrosepticus*); leaf-curl or leaf-roll; mosaic; scab (*Actinomyces scabies*); dry rot (*Fusarium caeruleum*); and *Sclerotinia sclerotiorum* Bref.—Other diseases more briefly described include skin-spot (*Oospora pustulans*); sprain; *Botrytis cinerea*; black scurf (*Corticium Solani*); violet root rot (*Rhizoctonia violacea*); pink rot (*Phytophthora erythroseptica*); *Verticillium* wilt (*V. albo-atrum*); streak; silver scurf (*Spondylocladium atrovirens*); and pit rot.—*Frederick V. Rand.*

1345. HABERLANDT, G. Wundhormone als Erreger von Zellteilungen. [Wound hormones as the cause of cell-division.] (Sonderabdruck aus den Beiträgen zur Allgemeinen Botanik, herausgegeben von G. Haberlandt, Bd. II, Hft. 1.) 53 p., 12 fig. Gebrüder Borntraeger: Berlin, 1921.—In studying the action of wound hormones on cell-division, tubers, roots, and leaves were mechanically injured. The tubers were cut into thin slices a part of which were washed under a heavy stream of water for 5–20 minutes, another portion covered with a thin layer of potato tuber ground up in a mortar, while others were held as checks.—In the case of kohlrabi roots cell-division was very slight in the washed slices or at least less frequent than in the unwashed slices, whereas in sections covered with a thin layer of macerated tissue there was abundant cell division.—Examination of leaves showed that under the brown cut edges every cell of the outer layer had divided and typical wound cork formation had followed, while cells in the regions remaining green had not divided with the exception of mesophyll cells directly under the injured epidermis. It was found that macerated tissue often caused cell-division in other members of the same plant family whereas it had no effect at all or was injurious to members of other families.—Tests with plant-hairs, epidermal cells, and guard cells showed that injury to individual cells when not severe enough to kill them caused typical nuclear division.—*Lillian C. Cash.*

1346. HARA, KANESUKE. Sosai kwaki no byôki to sono yobôhō. [Diseases of vegetables and ornamental plants and their control.] 145 p., 17 fig. Yoshimi Shoten, Shidzuoka, 1920. [In Japanese.]—This is a popular account for the grower, dealing with the principal diseases of vegetables and ornamental plants in Japan and recommendations for their control. An appendix takes up insecticides and insects injurious to vegetables.—*Frederick V. Rand.*

1348. HASKELL, R. J. Relation of plant pathology to the newly organized Science Service. *Phytopathology* 12: 301–302. 1922.—Science Service with headquarters in Washington, D. C.,

has been organized for the purpose of gaining more rapid and accurate publicity for the results of scientific research by furnishing newspapers with accurate and well written articles. This outlet for popular articles on plant pathology presents an excellent opportunity to get information before the people in an easy, quick, and effective way.—*B. B. Higgins.*

1349. HOWARD, ALBERT. Disease in plants. *Agric. Jour. India* 16: 626-637. *Pl. 35-36, fig. 1-2.* 1921.—A popular account of a paper on the influence of soil factors on disease resistance, which appeared in *Ann. Appl. Biol.* 7: 373. 1921. [see *Bot. Absts.* 11, Entry 558.]—The discussion includes rust in wheat, green fly on fruit trees, red-rot in sugar-cane, and wilt diseases of several crop plants in Bihar.—*A. Howard.*

1350. LEE, H. ATHERTON. Observations on previously unreported or noteworthy plant diseases in the Philippines. *Philippine Agric. Rev.* 14: 422-434. *Pl. 17-24.* 1921.—Brief notes are given on 49 diseases of citrus fruits, banana, abaca (Manila hemp), maguey (Agave), pineapple, tobacco, coconut, and sugar-cane. Twenty-two of the diseases listed are recorded from the Philippines for the 1st time. A short general discussion concludes the paper.—*E. D. Merrill.*

1351. LEE, H. ATHERTON, AND MARIANO G. MEDALLA. The season's experiments on Fiji disease, mosaic disease, and smut of sugar cane. *Philippine Agric. Rev.* 14: 402-412. *Pl. 1-8.* 1921.—The season's experiments with Fiji disease of sugar cane show that germination of points from affected canes is much poorer than from healthy and that the occurrence of the disease is not directly connected with soil conditions but is transmitted by cane cuttings. The spread from diseased to adjacent healthy plants was surprisingly low throughout the season. The results show that the losses from this disease are largely due to the use of points or cuttings from diseased stools.—The results with mosaic of sugar-cane showed that the germination of points from affected stools is usually poorer than from healthy stools and that the disease may be produced at will on any soil irrespective of drought by using points from diseased stools. The experiments corroborate those in Java, Hawaii, and Porto Rico as showing that cuttings from diseased stools reproduce mosaic in a large percentage of cases, usually 100 per cent. An unexpected result was the very small amount of transmission from affected to healthy stools during the past season under Canlubang conditions. It is evident also that in the course of the season a small portion of plants may grow out of the disease to such an extent that leaf signs are no longer visible.—Experiments with cane smut showed that germination of points from smut-infected stools is reduced, that a large percentage of points or cuttings from such stools reproduce the disease, and that the cane yield in such cases is usually a total loss. In the 6 months under experiment the spread to healthy stools in the field was very small. Points from healthy stools soaked in the same receptable with cane from smutted stools showed 8.33 per cent of resulting canes affected.—Planters growing susceptible varieties should select "seed" only from healthy stools.—*Frederick V. Rand.*

1352. LEE, H. ATHERTON, AND GONZALO MERINO. The prevention of the importation of injurious insects and parasitic fungi on economic crops from foreign countries. *Philippine Agric. Rev.* 14: 389-401. 1921.—This is a brief discussion of the author's Philippine experiences, with copies of local regulations adopted and a list of fruits prohibited from entry into the Philippines.—*E. D. Merrill.*

1353. MARLATT, CHARLES LESTER. Protecting the United States from plant pests. *Nation. Geog. Mag.* 40: 205-218. *16 fig.* 1921.—Insect and fungous enemies of plant life are discussed and illustrated, emphasis being placed on the quarantine measures now protecting the country against their introduction.—*W. M. Atwood.*

1354. MOLL, FRIEDRICH. Untersuchungen über Gesetzmässigkeiten in der Holzkonservierung. Die Giftwirkung anorganischer Verbindungen (Salze) auf Pilze. [An investigation of the chemical laws underlying wood preservation. The toxic action of inorganic com-

pounds (salts) on fungi.] Dissertation, Berlin, 1920: 23 p. 1920. [Published also in Centralbl. Bakt. II Abt. 51: 257-279. 1920 (See Bot. Absts. 10, Entry 788).]—A brief introduction and review of previous studies on wood preservation is followed by an account of the present investigation from which the author concludes that the poisonous or antiseptic action of salts is an additive character of their ions. In the sequence of their antiseptic activity the ions are: mercury, silver, cadmium, cyar, copper, zinc, cobalt, chromium, and fluorine. Most acid ions and the ions of the alkaline metals, alkaline earths, and aluminium may be considered inactive. The antiseptic action, using *Penicillium glaucum* and *Merulius* sp. as indicators, depends on the solubility and ionization of the salts in water. The specific antiseptic action is dependent on a specific chemical reaction. Admixture of other salts to the active substances may either retard or accelerate the disinfectant action but the end result is unaltered. The activity of a given quantity of a soluble salt or salt mixture depends only on the quantity of active ingredients in the mixture and on their specific activity. The static activity is dependent on the stoichiometric laws of chemical reactions. In so far as the salt mixture does not yield insoluble precipitates or complex compounds the individual ions retain their specific activity, and the activity of the mixture may be conceived as the sum of the activities of the individual ions.—*Frederick V. Rand.*

1355. NAVEL, HENRI C. Les principaux ennemis du cacaoyer aux Iles de San-Thomé et de Principe. Rapport sur une mission d'étude agricole et phytopathologique. [The principal enemies of cacao in the Islands of Saint Thomas and Principe. Report of an agricultural and phytopathological survey.] 135 p., 32 pl. (4 colored), 3 fig., 2 maps. Émile Larose: Paris, 1921.—An introduction gives the situation, size, geography, geology, and climate of these islands, and a general discussion of cacao enemies.—The body of the work takes up in turn the non-parasitic troubles, animal parasites (principally insects), and cryptogamic diseases of this host.—Among the non-parasitic troubles some space is given to a discussion of wounds, lack of proper hygienic measures, suppression of shade, insufficient rainfall, faulty methods of planting, drainage troubles, opening of holes for planting and manuring, and sudden death of the trees.—The principal animal parasites discussed are: *Heliothrips rubrocinetus* Giard. (thrips), *Helopeltis* sp., *Nisotra Theobromae*, *Aspidiotus trilobitiformis* Green and other species of cochineal insects, *Lygidus varicolor* Berlioz, *Zeuzera Coffeae*, *Eulphonolotus myrmeleon* Feld, *Mallodon Downesi* Hope, *Apate Monachus* L. (the last 3, borers), *Neoterme gestri* F. Silv., *Microcerotermes parvus Theobromae* Dess., and *Mirotermes Amaralii* Seabra (the last 3, termites).—Among mammalian enemies, rats and monkeys are discussed and several other animal parasites are briefly noted.—The cryptogamic diseases taken up in detail are those caused by *Phytophthora Faberi* Maubl. (mildew and canker), *Lasiodiplodia Theobromae* (Pat.) Griff. & Maubl., drying of the ends of branches due to the combined effects of bad climatic and cultural conditions but accompanied by *Fusarium*, *Nectria*, and other apparently saprophytic fungi, and various forms of decay. Added notes are given relative to several other cryptogamic diseases of cacao.—A chapter on the general principles of culture and maintenance is followed by an appendix in which are discussed a disease of the palm-oil tree (*Elaeis guineensis*) caused by *Ganoderma applanatum* Pers.; injury to the cocoanut tree caused by the beetle *Oryctes latecavatus* Fairm.; and the preparation of fungicides and insecticides. A list of the principle publications on cacao concludes the work.—*Frederick V. Rand.*

1356. NOWELL, WM. Report on an investigation of frog hopper pest and diseases of sugar-cane in Trinidad. Bull. Dept. Agric. Trinidad and Tobago 18: 57-69. 1919.—This report is a discussion of the "root disease" of sugar cane in Trinidad and the relation of the frog hopper and species of *Marasmius* and *Odontia* to this disease. Remedial measures, such as sanitation, rotation, and manuring, are advised.—*Florence A. McCormick.*

1357. PEACOCK, N. D. The less common spray materials. [Abstract.] Phytopathology 12: 251-252. 1922.

1358. PEGLION, VITTORIO. Le malattie delle piante coltivate cagionate da parassiti vegetali o da agenti inanimati. [Diseases of cultivated plants due to vegetable parasites or

non-living agents.] 4th rev. and amplified ed., 663 p. Casale Monferrato: Ottavi, 1922.—The preliminary chapters deal with general subjects such as the economic significance of diseases with special reference to the crop, the scope of plant pathology, the classification of plant diseases, virulence, parasitism and resistance, fungicides and their application. The diseases of different crops are then treated in turn; in each case the causal organism, its effect on the host, and preventive treatment are considered.—*Lillian C. Cash.*

1359. RAMSAY, A. A. "Liquid sulphur." Agric. Gaz. New South Wales 33: 525. 1922.—Sodium sulphide has been recommended as a ground treatment under orchard trees. If there is virtue in the method there appears to be no reason why lime-sulphur should not be substituted.—*L. R. Waldron.*

1360. RAMSAY, A. A. Two investigations in relation to sprays. Agric. Gaz. New South Wales 33: 513-514. 1922.—With home-made tobacco infusions the end result relative to the degree of acidity is not essentially changed whether anhydrous sodium carbonate is or is not used. In the preparation of a triple-purpose spray consisting of Bordeaux mixture, tobacco extract, and lead arsenate the amount of soluble arsenic found in the filtrate after 2½ days was safely below the allowable minimum.—*L. R. Waldron.*

1361. RAND, FREDERICK V. Insects as disseminators of plant diseases. I. Results of past investigations. Phytopathology 12: 225-228. 1922.—In a brief discussion and summary of the results of previous work on the relation of insects to the dissemination of plant diseases, insect dissemination as a whole is divided, according to type, into 5 groups: (1) external dissemination and direct inoculation; (2) external dissemination without direct inoculation; (3) wound infection from sources other than the wounding agent; (4) internal mechanical (unchanged), and (5) internal biological dissemination (multiplying within the carrier).—By means of a table and brief discussion the author states that proof or strong evidence of insect dissemination has been published for 1 protozoan, 16 bacterial, and 41 fungous diseases; and for the filterable contagium group of diseases as affecting 66 hosts.—*B. B. Higgins.*

1362. SANDERS, T. W. Fruit foes. 106 p., 29 pl. (13 colored), 31 fig. W. H. & L. Collingridge: London, 1921.—This handbook deals with "the various insect, animal and fungal pests that attack fruit trees, with remedies for their prevention and eradication."—Under each of the following hosts, alphabetically arranged, is taken up its particular enemies: apple, apricot, blackberry, cherry, currant, fig, gooseberry, loganberry, nuts, peach and nectarine, pear, plum and damson, raspberry, strawberry, and the vine.—Parts II and III deal with sprayers and spraying, and with insecticides and fungicides.—*Frederick V. Rand.*

1363. STEVENS, H. E. Avocado diseases. Florida Agric. Exp. Sta. Bull. 161. 23 p., 6 fig. 1922.—All available information on avocado diseases in Florida is brought together.—Avocado scab (*Cladosporium Citri* Massee) as a disease of the foliage and fruit is most common on young plants in the nursery, where it is difficult to control. It is especially a foliage trouble on the varieties of the West Indian group but fruits of the varieties Trapp, Taylor, and Fuerta are also very susceptible. Infection takes place only on the tender young growth, plants becoming immune when the leaf tissue hardens. In the nursery badly infected old leaves should be sprayed with 4-4-50 Bordeaux mixture before new growth starts. After new growth begins spraying with ammoniacal copper carbonate solution should be repeated weekly until growth becomes hardened. A 3-3-50 Bordeaux mixture is sufficient to control scab on the fruit. On the lower East Coast of Florida black spot (*Colletotrichum* sp.) causes much loss in seedlings. These spots are round, brown to dark brown or black, $\frac{1}{8}$ – $\frac{1}{2}$ inch in diameter, and the dry, hard tissues penetrate the skin of the fruit to the flesh, less matured fruit sometimes becoming misshapen. Spots also appear on the bark of young shoots. Bordeaux mixture (4-4-50) gives some control here. A 2nd application should follow 3-4 weeks after the 1st. Avocado blotch (*Cercospora* sp.) which frequently occurs first, and black spot are often found together. Avocado blotch causes a surface spotting on seedling fruits, spots being $\frac{1}{8}$ – $\frac{1}{4}$ inch in

diameter. Its control is similar to that of black spot. Rusty blight (*Glæosporium* sp.) is troublesome in Hawaii and may be present in Florida. Other diseases mentioned are powdery mildew (*Oidium* sp.) of the foliage, though this is not likely to be troublesome; and russet fruit, which injures the fruit.—*J. C. Th. Uphof*.

1364. TICE, C. Seed potato inspection and certification in British Columbia. *Sci. Agric.* 2: 249-251. 1922.—The author presents a statement of the percentages of disease allowed.—*B. T. Dickson*.

1365. WENIGER, WANDA. Potato diseases and their control. (In: *Potato hand book*.) North Dakota Agric. Exp. Sta. Ext. Div. Circ. 50. 14-19, fig. 1-3. 1922.—Following a key to potato diseases, a brief popular discussion is given of disease control by rotation, seed treatment, selection, storage, and handling.—*Frederick V. Rand*.

PHARMACEUTICAL BOTANY AND PHARMACOGNOSY

H. W. YOUNGKEN, *Editor*

E. N. GATHERCOAL, *Assistant Editor*

(See also in this issue Entries 983, 1142, 1511, 1520)

1366. ANNETT, HAROLD E. Investigations of Indian opium. *Pharm. Jour.* 108: 192-193. 1922.—The investigation deals with the influence of environmental factors, such as manures, climate, season, and stage of development of the capsules on the quantity and quality of the opium produced. In 1 series 1,000 terminal capsules gave 31.4 gm. of dry opium containing 15.7 per cent of morphine, while 1,000 lateral capsules gave 12.8 gm. of dry opium, containing 8.2 per cent of morphine. The yield of morphine was greatest from opium collected about 8-16 days after flowering. Cattle manure, nitrates, phosphates, or seed cakes alone or in combination over 4 years had but slight influence on the morphine yield of opium but did increase the total yield of opium. Weather conditions have little effect on the morphine yield but a very notable effect on the opium yield. With pure seed and equally good methods of cultivation opium produced on the plains or in the hills of India runs as high in morphine content as Turkey opium.—Morphine is produced during the period of active growth at the same rate as the plant tissues; it accumulates in the capsule but is not used in the ripening of the seed; the theory that it is an end-product of metabolism, excretory in nature, seems to be borne out.—*E. N. Gathercoal*.

1367. BENNETT, C. T. Oil of Cade. *Pharm. Jour.* 107: 166. 1922.—Genuine Cade oil must be derived exclusively from the wood of *Juniperus oxycedrus* by dry distillation. It has always been somewhat variable in character, particularly as regards specific gravity. In the British Pharmacopoeia it is "about 0.990"; in the United States Pharmacopoeia the specific gravity is stated as "0.980 to 1.055 at 25°." During the last few years there has been difficulty in obtaining this oil with the specific gravity over 0.975. It is now produced commercially mostly in Spain, and genuine Spanish oil may run as low as 0.955.—The bushy shrub of Juniper grows abundantly in the chalky marl of Provence and adjacent provinces. The heartwood is richest in oil, increasing in its content towards the roots. The bark is removed and the wood chipped as small as possible. The dry or destructive distillation is performed in cast-iron boilers, filled with shavings or chips of the wood, with a delivery tube at the bottom and by means of a brisk fire of wood completely surrounding the boiler. The blackish viscid distillate upon standing for a considerable time separates into 3 layers, the oil of Cade being uppermost. Spanish Cade oil, though of low specific gravity, can be accepted as genuine; it contains a high proportion of cadinene.—*E. N. Gathercoal*.

1368. BURTT DAVY, JOSEPH. Utilization of maize flowers. Stalks and leaves 1. *South African Jour. Indust.* 5: 324-329. 1922.—This instalment deals with the medicinal uses and

properties of maize silk (*Stigmata Maydis*) and maize smut (*Ustilago Maydis*). It also contains a preliminary paragraph on the utilization of Maize stalks as a source of syrup, cane sugar, alcohol, etc.—*Sydney M. Stent*.

1369. COMPTON, R. H. Medicinal and aromatic plants in South Africa. Jour. Bot. Soc. South Africa 8: 9-11. 1922.—Aloes is the evaporated juice of the leaves of *Aloe ferox*. *Buchu folia* is the dried leaf of *Barosma betulina*, *B. crenulata*, and *B. serratifolia*. "Bitter blaar" (*Brachylaena elliptica*), "Kankerbos" (*Sutherlandia frutescens*), "Zandolien" (*Dodonea Thunbergiana*), and "Kruidje-roer-my-niet" (*Melianthus niger*) are highly esteemed home-made medicaments. The possibility of producing essential oils in South Africa is being studied at Kirstenbosch.—*E. P. Phillips*.

1370. COUCH, JAMES F. Note on the oil of *Agastache pallidiflora*. Amer. Jour. Pharm. 94: 341-343. 1922.—Having had his attention directed to this plant by the intense fragrant odor, the author subjected several lots of the flowering heads and leaves to distillation. The flowers yielded 0.184-0.316 per cent of oil and the leaves 0.083 per cent. The oils obtained from the flowers possessed a penetrating peppermint odor with a marked suggestion of thyme, while the oils from the leaves possessed a rank thyme odor. Physical constants for the oil from the flowers are: density at 20°, 0.91924; specific rotatory power at 25°, 8.60; index of refraction at 25°, 1.4865. No separation of crystalline material was obtained by cooling and the tests for phenols were negative.—*Anton Hogstad, Jr.*

1371. E[ATON], B. J. Ipecacuanha. Alkaloidal content of leaves and stems. Agric. Bull. Federated Malay States 9: 178. 1922.—In the roots the percentage of alkaloids was found to be 2-2.5, of which $\frac{1}{2}$ - $\frac{3}{4}$ was emetine; in the stems and leaves the amount of alkaloids was 1.5 per cent, of which 0.45 was emetine.—*I. H. Burkill*.

1372. EZENDAM, JOH. A. De kwantitatieve botanische analyse van veevoedermiddelen. [The quantitative botanical analysis of feeding cakes.] Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefsta. 25: 1-82. Pl. 1-6. 1921.—The author explains the advisability of a quantitative analysis of feeding cake, etc., to determine its purity. He mentions and discusses the most important methods of analyzing linseed cake and those used for analyzing other feeding cakes. The methods investigated and the author's comment on their general or specific practicability are as follows: (1) Method of Pesch,—impractical. (2) Method of Schaffnit,—impractical. (The author's modification of this method is too lengthy, and is practicable only for linseed cake investigation.) (3) Method of Grevillius,—too time consuming and practicable only for linseed cake. (4) Method of Schoute,—the same conclusion as in (3). (5) Netherlands or counting method,—useful only for linseed cake and rapeseed cake investigations. (6) Mechanical-optical analysis of van Weinzierl,—not sufficiently accurate and practical only for special cases. (7) Method of Kühn,—very good for quantitative analysis of those particles which have a much higher or lower specific weight than the feeding cake in which they are present; therefore useful only in special cases. (8) Method of Hintner,—may be used in some cases where the particles to be analyzed are coarse and may easily be recognized or made recognizable. (9) Method of Kole,—practical for determination of contents of cottonseed husks in cottonseed meal. (10) Method of Arthur Meijer, like the method of Huss, is practical when there are particles present which can be used for measurements. The author developed a method in which the principle was to find an element for measuring in those cases in which the amount of a certain constituent could not be found from a comparison by counting (Netherlands method), or from a comparison by measuring (method of Schoute), or when no measurable elements or particles were present, according to the method of Arthur Meijer. The author grinds a sample of the cake until it passes a screen with circular holes 1 mm. in diameter. A definite quantity (0.5-2 gm.) is boiled with acids and alkali and washed with hot water on muslin cloth (43 threads per cm., opening in wet cloth \approx 100 μ). The remaining substance is mixed with 10 cc. of a mixture of glycerine and water (1:1). This is spread on a special glass plate and measurements are made with a Nebelthau or similar micro-

scope, using objective 3 and net micrometer-ocular 3 of J. C. Schoute. After 15 minutes particles are measured in at least 3 strips and at least 300 fragments. Measuring is the determination of the number of squares each particle covers. Then the sum total of the squares covered by all particles is divided by the number of grams used, the total surface of the rows (each row is 1.2 square cm.), and by the normal number. The number obtained gives the percentage of the impurity or particles present.—The normal number is the number of squares covered by the fragments of impurities, or of a certain substance, present on 1 square cm. using 1 gm. of a 1 per cent mixture of impurity or substance. The normal number must be determined for each impurity or substance. The author states that the usefulness of this method depends mainly upon the exactness of the normal number. Plates give photographs and drawings of some of the impurities investigated. Investigations were made and normal numbers determined for the following impurities or admixtures: rice husks, barley husks, ground nut shells, coffee husks, cacao husks, soy bean, and impurities in linseed cake. [See also Bot. Absts. 11, Entry 647.]—*Peter J. Klaphaak.*

1373. FARWELL, O. A. Botanical source of the cola nut of commerce. Amer. Jour. Pharm. 94: 428. 1922.—Quoting I. H. Burkill in Notes on Cola Trees in the Economic Garden, Singapore [see Bot. Absts. 8, Entry 1540], the author states that the *Sterculia acuminata* Beauv. of Benin does not produce the Kola Nut of Sierre Leon, which is the Kola of commerce, but that the larger part is derived from *Sterculia nitida* Vent. He also points out that *Bichea* Stokes (Bot. Mat. Med. 2: 564. 1812) is the oldest generic name for these species and therefore *Sterculia nitida* Vent. Jard. Malm. sub. t. 91, 1804, should be *Bichea nitida* (Vent.) Farwell n. comb.—*Anton Hogstad, Jr.*

1374. FARWELL, O. A. *Osyris alba* substitute for *Scoparius*, N. F. Amer. Jour. Pharm. 94: 429. 1922.—Attention is called to the fact that *Osyris alba* is again making its appearance as a substitute for Broom Tops, to which it bears a close resemblance. It may however be detected by the following characters: (1) the stems are many-striate instead of 5-angled or winged; (2) the buds are at the apex of an angle, which forms a keel on the dorsal side of the bud, instead of in the channels between the angles; (3) the wood is white instead of yellowish.—*Anton Hogstad, Jr.*

1375. GARRIGUES, A. Les plantes en médecine: le seigle et l'ergot. [Medicinal plants: rye and ergot.] 254 p., 22 fig. Libr. Octave Doin: Paris, 1921.

1376. GATHERCOAL, E. N., and R. E. TERRY. What is aloes, U. S. P.? Jour. Amer. Pharm. Assoc. 11: 523-526. 1922.—In reviewing the characteristics of, and the various tests applied to aloes, the authors suggest that it is no longer worth while to differentiate between the 3 kinds of aloes, especially from a therapeutic standpoint, since no physician specifies the use of any particular kind of aloes or aloin. They suggest that, as the value of aloes is not entirely due to aloin, there is excellent opportunity for study of the therapeutic activity of aloes compared with aloin.—*Anton Hogstad, Jr.*

1377. GUNTON, J. A., and G. D. BEAL. A reinvestigation of the proximate composition of *Rhamnus frangula*. Jour. Amer. Pharm. Assoc. 11: 669-682. 1922.—In this investigation to determine whether the anthraquinone derivatives were present in the free form or principally in combination, possibly as a glucoside, the glucoside frangulin was found to agree in properties with that which has been previously described; M. P. 229°, and upon hydrolysis yielding emodin and rhamnose. Emodin, the principal hydroxyanthraquinone present, was found in both free and combined forms and agrees with the properties of that from *Cascara* and *Rumex crispus*; M. P. 253°. Chrysophanic acid was found free and associated with monomethyl ether; M. P. 190°. Various other constituents resulting from the analysis are discussed.—*Anton Hogstad, Jr.*

1378. HEYL, F. W. Some constituents of *Viburnum opulus*. Jour. Amer. Pharm. Assoc. 11: 329-336. 1922.—By extracting the drug with methyl alcohol and pouring the extract into water, a resin was obtained in which acetic, valerianic, caproic, caprylic, formic, oleic, linoleic, cerotic, and palmitic acids were found in the ligroin extract.—Anton Hogstad, Jr.

1379. HOLMES, E. M. Oregon balsam. Pharm. Jour. 108: 146-147. 1922.—The author reviews and compares the source, method of collection, and uses of Canada balsam and Oregon balsam. As the cost of Oregon fir balsam is about $\frac{1}{3}$ that of Canada balsam, it will probably replace the latter for many purposes, except in microscopic technique.—E. N. Gathercoal.

1380. HOPKINS, J. L. Crude drugs—their selection and milling. Jour. Amer. Pharm. Assoc. 11: 521-523. 1922.—The author remarks briefly on the great care exercised in collecting, milling, and examining crude drugs in order that the materials may represent the highest percentage of purity and potency.—Anton Hogstad, Jr.

1381. KABAYAO, D. S. The effect of heating *Cocculus indicus* in relation to chemical identification of picrotoxin. Amer. Jour. Pharm. 94: 425-428. 1922.—By heating the kernels in a nickel crucible over a free flame and then extracting by the modified Stass-Otto, method the extracted poison gave a negative reaction with Langley's reaction and also with Fehling's solution. The extracted poison, however produced the typical picrotoxin convulsions when injected into the dorsal lymph sac of the frog. In another experiment the kernels were heated in an oven at 104°C. and extracted as above. In this case the Langley and Fehling reactions, as well as the physiological reaction, were positive. By heating commercial picrotoxin above its melting point (203°C.) negative tests were obtained with Langley's and Fehling's solution. By these experiments the author has shown that the intramolecular rearrangement is due to heating at a high temperature and probably not to oxidation changes, as one heating experiment was carried on in a stream of hydrogen. The author states that the commonly recognized tests for the identification of picrotoxin cannot be depended upon when, as is the custom, the berries have been roasted over a free flame.—Anton Hogstad, Jr.

1382. KARSTEN, GEORGE, und WILHELM BENEKE. Lehrbuch der Pharmakognosie. [Text book of pharmacognosy.] 8 vo, 3rd ed., vi + 398 p., 544 fig. Gustav Fischer: Jena, 1920.

1383. LAVIALLE, P. Les plantes médicinales. [Medicinal plants.] Mulhouse, 1921.

1384. LLOYD, J. U. Vegetable drugs. The Caxton: Cincinnati, 1921.

1385. MACBETH, ALEXANDER KILLEN, and ROBERT ROBINSON. Cevadine. Part I. Jour. Chem. Soc. [London] 121: 1571-1577. 1922.—The paper deals with the optical activity, products of hydrolysis, and distillation compounds of cevadine, a crystalline alkaloid occurring in the mixture of bases termed "veratrine," first isolated from the seed of *Veratrum sabadilla*.—F. E. Denny.

1386. MUSZYNSKI, JAN. Investigations of Polish foxglove. Pharm. Jour. 107: 443. 1922.—There are 2 kinds of foxglove in Poland,—*Digitalis purpurea* L. and *D. ambigua* Murray,—though the former is very rare. The latter is abundant throughout almost every part of the country and is collected not only for local uses but also for export. An examination of the physiological action of the 2 plants cultivated at the state medicinal farm was made, the physiological method of Focke using *Rana esculenta* being employed. Strophanthinum Crystal, Merck, 1: 10,000, was always used as a check. About 200 experiments were carried out. The following conclusions were reached: (1) *D. ambigua* should be accepted by pharmacopoeias as the substitute of *D. purpurea*. (2) The garden foxglove (*D. purpurea* var. *gloxiniæflora*) produces a good drug. (3) The requirements of pharmacopoeias should permit the collection of flowers and leaves of the 1st year's growth. (4) A physiological assay of foxglove is necessary for its control.—E. N. Gathercoal.

1387. PARRY, E. J. **The chemistry of essential oils and artificial perfumes. I. Monographs on essential oils.** 4th ed., rev. and enlarged, viii + 549 p., 52 fig. Scott, Greenwood & Son: London; D. Van Nostrand Co.; New York, 1921.

1388. PRICE, E. A., and NOEL L. ALLPORT. **An improved method of preserving specimens for a herbarium.** Pharm. Jour. 108: 9-10. 1922.—The plant parts are placed between white blotting paper, 6 sheets above and 6 below, and pressed for 20 minutes with an ordinary 2-pound flat iron heated to about 110°C. There should not be sufficient heat to decompose the chlorophyll or other coloring matters. The plant parts become dry and rigid but otherwise retain their natural appearance and color. The specimen should be painted over with a 0.5 per cent solution of mercuric chloride in absolute alcohol and mounted on herbarium paper with mucilage of acacia. The leaves or flowers may be separated from the axis and the latter partially or wholly dissected. After the preservation treatment the parts are strong and inflexible and there is no difficulty in reassembling the parts. With the Compositae and Orchidaceae especially successful work has been done. A collection of plants preserved and mounted as described has retained the color of both flower and foliage for 8 years.—E. N. Gathercoal.

1389. SMALL, JAMES, and F. M. J. ADAMS. **Yohimbe bark: Its history and identification in commerce.** Pharm. Jour. 108: 282-285, 311-314. 12 fig. 1922.—Genuine yohimbe bark, derived from *Pausinystalia Yohimba*, usually occurs in channelled pieces, 4-10 mm. thick, with a varying tinge of red in the grey-brown or brown outer and inner surfaces; the outer surface is longitudinally furrowed, the edges of the furrows scarcely or not at all raised above the general level of the surface; numerous narrow transverse cracks occur on the outer surface at fairly regular intervals of 1-2 cm.; the cork adheres closely. Occasionally such bark is derived from very old tree trunks, and is then dark red on the inner and cut surfaces; 15-20 mm. thick; with a scaly outer bark showing few or no transverse cracks. Occasionally also this bark seems to be derived from the smaller branches rather than from the trunk of the tree, and is then much thinner, 2-3 mm. thick; while the transverse cracks are very narrow, shallow, and inconspicuous, but still evident on careful inspection. Transverse sections under the microscope show a characteristic "beaded" alternation of bast fibers with parenchymatous cells, and also show little or no "twinning" of the bast fibers, especially in the outer zone of the bast where the rows are fewer. A few scrapings from the inner surface of the secondary bast, when shaken with dilute caustic soda solution (10 drops of a solution of NaOH, sp. gr. 1.168 in 30 cc. of water) give a red color, varying in different samples from wine-red to distinctly reddish-brown. Treated in the same way with dilute ammonia (5 drops of 0.880 solution in 10 cc. of water) the same colors are developed; this ammonia test is usually more distinctive but the color may develop more slowly. False yohimbe bark, derived from *Pausinystalia macraceras*, usually occurs in channelled, or flattened and severely scraped pieces; 4-15 mm. thick; with little or no red tinge; usually with a dark brown outer surface, showing, when unscraped, characteristic longitudinal furrows, the edges of which are puckered so that they stand up as rounded ridges above the general level of the surface; transverse cracks when they occur are few and very irregularly spaced; the cork frequently exfoliates easily. Transverse sections under the microscope show little or no "beading" in the radial rows of bast fibers, but do show "twinning" of these fibers; this feature, when it extends to the outer bast, is a good diagnostic character. A few scrapings from the inner surface, treated with caustic soda or ammonia as described above, give a brown color, with a faint tinge of red. The barks of *Pausinystalia Talbotii* Wernh., *Corynanthe paniculata*, and *C. Lane-Poolei* were examined and compared with true yohimbe bark. The illustrations are valuable and a table of diagnostic characters of each of the barks is appended.—E. N. Gathercoal.

1390. SMODLAKA, N. **The history and therapeutic properties of valerian.** Pharm. Jour. 107: 402-405. 1922.—Valerianic acid is considered the active principle of valerian, occurring in the drug as the borneol ester. This salt of the acid prepared synthetically has been used for some 20 years, but is not considered as satisfactory as the drug itself and does not re-

place the drug for the treatment of hysteria, neurasthenia, nor affections of the heart. This confirms once more Tschirch's hypothesis that in a drug, in most cases at least, not one or the other active principle is the exclusive therapeutic agent, but that the physiological effect is a result of the complex of active principles. One of the best galenicals is the dialysate, prepared from the fresh root in which the enzyme has been destroyed by heating the root to 80°C. in acidulated water. This process is known as stabilization. The author found that he could stabilize valerian by keeping it in vacuo above boiling water for ten minutes at 100°C. Preparations made by extraction with alcohol and with ether gave extractions that were equally fit if not superior to the extract obtained by dialysis. In fact, it would appear that the therapeutic effect is due to the resin contained in the drug rather than to volatile oil. This hypothesis is borne out by pharmacodynamic experiments with frogs. Extract in aqueous or hydro-alcoholic solution cannot be kept in good condition; it deteriorates very quickly in contact with water. The ethereal tincture of the fresh stabilized drug is undoubtedly the best form in which to preserve the active principles.—*E. N. Gathercoal*.

1391. STENT, SYDNEY M. "Dubbeltje" (*Tribulus terrestris*) and Geeldikkop in sheep. Jour. Dept. Agric. Union South Africa 4: 548-551. 1 fig. 1922.—This weed belongs to the family Zygophyllaceae and bears fruit armed with sharp-pointed spines. In certain stages of growth under certain climatic conditions it is poisonous to sheep and goats, and it has been determined that when these animals grazed on dubbeltje veld during hot sunny days, succeeding a heavy fall of rain, when the plant is green and succulent and in the flowering stage, are certain to contract the disease "Geeldikkop" (*Tribulosis avium*). This disease is described and remedies prescribed.—*L. Goldblatt*.

1392. STENT, SYDNEY M. Poisonous properties of Sudan grass. Jour. Dept. Agric. Union South Africa 4: 446-447. 1922.—This grass, like the ordinary sorghum, sometimes causes poisoning in stock owing to the presence of a compound of prussic acid. Glucose, dextrose, and other sugars act as antidotes, while a teaspoonful of soda dissolved in a pint of diluted vinegar has been found an effective remedy. Feeding the animals on starchy food before turning them into the Sudan grass diminishes the danger of poisoning. When made into hay Sudan grass is very unlikely to be harmful.—*L. Goldblatt*.

1393. TANRET, GEORGES. Sur la composition chimique de l'ergot de diss et de l'ergot d'avoine. [On the chemical composition of the ergot of *Ampelodesmos* and of oats.] Compt. Rend. Acad. Sci. Paris 174: 827-830. 1922.—The ergot of *Ampelodesmos tenax*, a plant of northern Africa, and that of oats have the same medicinal principles as does the ergot of rye. The ergot of *Ampelodesmos* is low in crystallizable ergotine; while that of oats has a higher ergotine content than the ergot of rye.—*C. H. Farr*.

1394. VIEHOEVER, ARNO. Problems, we, as officials, have in common with the trade. Jour. Amer. Pharm. Assoc. 11: 592-595. 1922.—The author discusses some of the many problems confronting the honest dealer in crude drugs and the officials entrusted with the enforcement of the U. S. A. Foods and Drugs Act. Among the problems considered are methods of collection, drying, cleaning fresh drugs and spices, storing, and sampling. Reference is included to some of the tests applied during the course of examination of crude drugs.—*Anton Hogstad, Jr.*

1395. WHELAN, JULIA. Oil of *Bystropogon canus*. Jour. Amer. Pharm. Assoc. 11: 337-338. 1922.—Upon subjecting 28 pounds of herb to distillation, 25.5 gm. (= 0.2 per cent) of oil separated from the aqueous distillate and 13.7 gm. were obtained by 3 cohobations. Both oils were of greenish color, not unlike Bergamot oil. The original oil appeared to have more of the nature of fatty acid esters than of menthol. Tests, for pulegone, thymol, menthol, and carvacrol were negative. On account of the small amount of oil at hand no chemical examination was made. A few constants are included.—*Anton Hogstad, Jr.*

1396. YOUNGKEN, HEBER W., and C. H. LAWALL. *Anatomical and chemical studies of the sand spur (Cenchrus tribuloides L.)*. Amer. Jour. Pharm. 94: 567-583. Fig. 1-14. 1922.—In their endeavor to ascertain the cause for the inflammation, which is in many instances induced by the spines of the plant, the authors find that their tests tend to show that formates may be present in certain cells of the epidermis, sclerenchyma fibers, and barbs of the younger spines of the burs. Tests for alkaloids as well as for glucosides or other similar toxic principles were negative. Various extracts made from mature burrs with water, ether, petroleum, or alcohol lacked activity or irritating properties as indicated by taste or by inoculation with pin prick. The authors have also reviewed the previous literature and have presented detailed anatomical characters which are accompanied by many original figures.—*Anton Hogstad, Jr.*

GENERAL

1397. KAYSER, E. *Microbiología agrícola, aplicada a la fertilización del suelo*. [Agricultural microbiology with application to soil fertility.] [Translation from the 4th French ed.] 351 p., 49 fig. P. Salvat: Barcelona, 1921.—This volume is one of a series of works constituting an "Encyclopedia of Agriculture" and at the time of its appearance 29 had been published, and 5 others were in press or in preparation, all dealing with applied sciences or technical agriculture. In part 1 of the present volume 21 pages are devoted to a general discussion of microorganisms, and 36 pages to the influence of physical and chemical agents upon such organisms, including a discussion of culture methods and staining properties. In part 2 (269 p.) there are treated successively the distribution of microorganisms in the superficial layers of the soil, the formation of humus, nitrification, decomposition phenomena, denitrification, purification and use of sewage, fixation of nitrogen, and the cycle of sulphur and iron. In an appendix of 13 pages the importance of soil reaction and methods of determining H-ion concentration are succinctly presented.—*B. M. Duggar.*

DIFFUSION, PERMEABILITY, PHYSICO-CHEMICAL PHENOMENA

1401. CHURCHMAN, JOHN W. *The selective bacteriostatic activity of sulfanilic acid*. Proc. Soc. Exp. Biol. and Med. 19: 317-318. 1922.—The sulfonic acid groups in acid-fuchsin are responsible for its ability to kill gram-negative organisms while sparing gram-positive aerobes. This affords data for determining the cause of the difference between these 2 types of organisms.—*M. M. Brooks.*

1402. DAHLBLOM, TH. *Osmotiska Trycket i Vattenlösningar och dess Betydelse en Disso-ciation och Lösighet*. [Osmotic pressure in aqueous solutions and its importance to ionization and solubility.] 53 p. Nordisk Rotogravyr: Stockholm, 1921.

1403. DOERR, R. *Kolloidchemische Wirkungen der Salze seltener Erden und ihre Beziehungen zu den Flockungsreaktionen der Antikörper.* [Colloid chemical action of the salts of the rare earths and their relation to the flocculation of antibodies.] *Kolloid Zeitschr.* 27: 277-292. 1920.—Salts of the rare earths (Th, Ce, Pr, and La) agglutinate suspensions of red blood corpuscles, bacteria, and fungous spores, and precipitate protein solutions even when the salt is not in the colloidal condition nor hydrolytically dissociated in solution. This occurs even in very dilute solutions (1 part thorium sulphate in 5,000-10,000 parts of the reaction mixture). Although Th with a valence of 4 is more active than La, Ce, or Pr with 3, the flocculating power is not dependent alone upon the valence but varies with unknown properties of the rare earth and of the protein. These salts are toxic for all protoplasm, but the mechanism is not a simple protein precipitation, for the precipitation is reversible in an excess of protein, whereas the poisoning is not. Spores of bacteria and fungi are not affected because of their impermeable membranes, their agglutination thus appearing to be a surface phenomenon. Protein precipitation is inhibited by an excess of either reactant, there is a minimal salt concentration below which flocculation does not occur, and this varies with the rare earth employed, being lowest for Th. Flocculation depends upon a weak union of protein and salt, as in flocculation with the heavy metals, the complex formed being colloid chemically inactive, easily reversible, dissolves quickly and completely in an excess of either protein or salt and the solvent action is proportional to the precipitating action. An analysis of the flocculant with Lowe's interferometer shows that the amount necessarily depends not only on the relative concentrations but also on the cation of the salt and is 3 times as great with a unit weight of Th as with 20 times this weight of cerium chloride. In many ways immune precipitation resembles protein precipitation by Th and Ce. It shows the same dependence upon the concentration of the reaction components, is prevented by an excess of one component, and is characterized by reversibility of the reaction product. The interferometer shows that the precipitate contains all the material lost from the solution, whether the precipitation was immune precipitation or that produced by rare earths, and this renders the conception of fermentative processes of the protein antigen unnecessary to account for the immune precipitate.—*H. E. Pulling.*

MORAX. *Recherches expérimentales sur la perméabilité des tissus vivants aux ions.* [Experimental studies on the permeability of living tissues to ions.] *Compt. Rend. Soc. Biol.* 87: 69-72. 1922.—This paper deals entirely with theoretical considerations of the selective permeability of the cell wall to ions.—*S. Morgulis.*

1405. HOOKER, MARION O., und M. H. FISCHER. *Ueber die Quellung und "Lösung" von Aleuron.* [Concerning the swelling and "solution" of aleurone.] *Kolloid Zeitschr.* 26: 49-58. 1920.—The natural mixture of plant proteins known as aleurone behaves in swelling and solution phenomena like the proteins previously investigated,—gelatin, fibrin, blood serum, and gluten. The degree of swelling does not run parallel to the concentration of the H ion nor of the OH ion, although acids and alkalies induce aleurone to swell more than does pure water alone. Neutralization does not stop swelling although the addition of neutral salts does. Swelling and solution are not the same although they often occur together and operate in the same direction.—*H. E. Pulling.*

1406. MONTFORT, C. *Die aktive Wurzelsaugung aus Hochmoorwasser im Laboratorium und am Standort und die Frage seiner Giftwirkung.* Eine induktive ökologische Untersuchung. [Active root absorption from bog water in the laboratory and in the field, and the question of its toxicity. An inductive ecological investigation.] *Jahrb. Wiss. Bot.* 60: 184-255. 1921.—The main thesis of this paper is that although bog water used in the laboratory does have a toxic effect on roots, Schimper's hypothesis of "physiological drought" in bogs must be either abandoned or greatly modified. Attention is called to the fact that some hydrophytes do occur in bogs and experiments are described indicating that bog plants absorb water readily from the bog substratum. The author used guttation and bleeding phenomena as a

measure of water absorption by roots. The validity of this method has been tested and reported [Jahrb. Wiss. Bot. 59: 467-524. 1920]. Seedlings of *Zea Mays* were placed in "sphagnum water" and in "secondary peat water," also bog plants (Hochmoorpflanzen) were placed in bog water (Sphagnum-Wasser der Rhizosphäre) each being covered with a moist bell jar. *Zea Mays* absorbed water more readily from sphagnum water and secondary peat water than from a nutrient solution or from tap water, though the difference regarding tap water disappears with time. The initial increase is greater in secondary peat water than in sphagnum water. Experiments with distilled water show that this increase as compared with nutrient solutions and tap water cannot rest solely on low osmotic pressure in the bathing medium. This action is not specific for acid bog water, since it is found also in the pit water from lignite coal which is chemically similar to "Flachmoor" water. Guttation and bleeding continued for weeks in bog plants in the laboratory in sphagnum water. Water loss is possible only with a corresponding rate of intake of water through the roots. When this rate of intake is decreased osmotically the giving off of water ceases.—Bog plants in secondary peat water first show an increase in the rate of water intake. The second stage of toxicity, the decrease in the rate of water intake, in this medium is reached earlier in *Eriophorum vaginatum* (a bog plant) than in *Zea Mays*. Bleeding of bog plants is stopped after 7 days in strong peat extract, while in sphagnum water both guttation and bleeding still continue. When plants in peat water have stopped bleeding they can be caused to bleed again by adding distilled water. A strong extract of the peat water used in these experiments is unquestionably toxic, while field observations indicated that the natural soil water bathing the roots of *Eriophorum* is not.—In the field work typical bog plants of the 3 ecological classes (hydrophytes, mesophytes, and xerophytes) were investigated in bogs in various localities and at different elevations. In primary raised bogs guttation occurred in all of the plants investigated except *Andromeda*, *Scirpus*, and *Juncus*. These bled only when the leaves were cut. *Eriophorum*, *Scheuchzeria*, and *Juncus* also show that water loss is not slower in the field than in the laboratory, and that such loss is dependent merely on the rate of water intake.—In secondary bogs the physical properties of the soil exert on the plants an influence that may be called "physiological drought" comparable to high osmotic pressure of the soil solution, but really independent of the chemical character of the water. Here it is a complex of soil factors that is important.—Even relatively weak bog water has a serious toxic effect on the root system of *Zea Mays* and other non-bog plants, the injuries being diverse; but those changes do not necessarily go hand in hand with the second stage of toxicity—the decrease in water absorption. The absorbing cells were living even when the growing tip was dead.—The roots of bog plants develop normally in bog water. Root hairs are not formed on roots that penetrated deep into the sphagnetum; but where formed, they show little or no toxic effects and their absence cannot be regarded as a symptom of toxicity. Normal root hairs develop in the drained peat of secondary raised bogs. Far-reaching conclusions on the ecology of bog plants cannot be drawn from observations on non-bog plants.—The author agrees with many of the American workers (Livingston, Transeau, Dachnowski, Rigg) as to the toxic effect of bog water and soil on the growth of non-bog plants, but conclusions cannot be drawn from these as to the behavior of bog plants in bogs. In relation to the ecology of bog plants there is an essential distinction between the physiological-ecological and the physico-chemical investigations of the American workers. The former have been somewhat misleading, while the latter have contributed much to an understanding of the complex of soil factors in bogs.—G. B. Rigg.

1407. NEUSCHLOSS, S. M. Untersuchungen über antagonistische Wirkungen zwischen Ionen gleicher Ladung. [The antagonistic action of ions of equal electric charge.] Kolloid Zeitschr. 27: 292-306. 1920.—The chlorides of alkalis, alkaline earths, and aluminum increase the surface tension of lecithin hydrosols, and by continued addition of salt the surface tension reaches a maximum. The same salts retard the action of invertase on cane sugar, and the greater the concentration of the salt or the valence of the cation the greater is the effect. The influence of salt on fermentation is paralleled by its effect on the dispersion of the ferment solution. Both processes are well represented by the adsorption isotherm. This leads to the belief that inhibition of ferment action by neutral salts is produced by diminishing the active

surface of the ferment. In all processes mentioned above, mixtures of the salts plainly exhibit antagonism. The surface tension of lecithin solutions, the inhibition of ferment action, and the surface tension of the ferment solution are chiefly, if not entirely, dependent upon the relative concentration of the cations present and independent, within wide limits, of the absolute concentration. The physico-chemical basis of the ion-antagonism lies in the ability of cations to force each other from their adsorption complexes into the surface of the colloid particles. This antagonism alters slightly the coefficient K of the adsorption isotherm which reaches its maximal value with maximum antagonism. The relative amounts at which the salts are maximally antagonistic is uniquely dependent on the valence of the cation. With cations of equal valence the ratio is 1:1; with one twice that of the other the ratio is 1:20; three times, 1:100. The only exception is when sodium and potassium salts act on the surface tension of lecithin solutions; in such an experiment the maximal action occurs not with the ratio Na:K = 1:1 but 1:20. Another maximum is found when the concentrations are in the ratio K:Na = 1:20. For this no explanation has been found.—*H. E. Pulling.*

1408. NEWTON, ROBERT, and ROSS AIKEN GORTNER. A method for the estimation of the hydrophilic colloid content of expressed plant-tissue fluids. *Proc. Soc. Exp. Biol., and Med.* 19: 356. 1922.—This method is based primarily on freezing-point determinations.—*M. M. Brooks.*

1409. PRIESTLEY, J. H., and DOROTHY ARMSTEAD. Physiological studies in plant anatomy. II. The physiological relation of the surrounding tissue to the xylem and its contents. *New Phytol.* 21: 62-80. 1922.—“At any moment certain cells around the vascular strand and within the vascular cylinder have especially permeable protoplasts: in some cases these protoplasts would seem to be more readily permeable by acid or basic ions.” If in *Vicia Faba* weak solutions of acid dyes (acid green or light green F. S.) are drawn up the xylem vessel of the root, certain cells of the pericycle, especially those just opposite the protoxylem, will be stained. On the other hand, basic dyes (malachite green) will stain the protoplasts of cells immediately adjacent to the xylem.—Under suitable conditions exudation pressures can be exhibited by stems and leaves as well as by roots (*Helianthus*, *Syringa*, *Ribes*, and *Spiraea*). Failure to obtain evidence of exudation pressure in the leafy twigs of *Fuchsia* is due to leakage from the hydathodes at the ends of veins, since blocking these permits the development of the exudation pressure. “The solutes present in the xylem sap are both organic and inorganic. As the organic solutes fell off in quantity in the sap rising from a cut vine [*Vitis*], the exudation pressure began to fail whilst the supply of inorganic solutes still remained approximately constant. Organic solutes would thus seem to be more directly responsible for the osmotic pressure effective in causing the flow of sap.”—Hydathode water of *Colocasia antiquorum* (Schott) is practically free from solute, probably due both to physical adsorption and to physiological absorption during the upward passage of the sap. The author observed such change in concentration of a fluid after it had been drawn through the stem of *Platanus*, *Ulmus*, *Syringa*, *Aesculus*, and *Acer*.—“The conception is developed of an equilibrium concentration for a sugar solution which would neither lose nor gain sugar during its passage through the xylem. This equilibrium concentration would vary in the same plant at different seasons,” being highest when the leaf buds are bursting.—*I. F. Lewis*

1410. REICHEL, H. Zur Wasser- und Ionenverteilung im Organismus. [Water and ion distribution in the organism.] *Biochem. Zeitschr.* 127: 322-326. 1922.—This is a critique and discussion of the physico-chemical aspects of the subject, with an account of an experiment with horse serum, tending to show that the change in indicator color (methyl orange) in acid protein solutions effected by addition of neutral salts does not controvert the idea that the colloid phase of the cell contents is salt-free and poor in H_2O , but that proper interpretation supports that view.—*W. W. Bonns.*

1411. STILES, WALTER. Permeability. *New Phytol.* 20: 137-149, 185-194. *Fig. 8.* 1921; 21: 1-14, 49-57, 140-162. *Fig. 4-6.* 1922.—Among the matters treated in Chapter 4 are: the

laws of diffusion, with equations for determining diffusion coefficients; methods used; a brief table of coefficients of diffusion of electrolytes and non-electrolytes; their relation to electrical conductivity and to molecular size; the influence of concentration and of temperature; and diffusion in heterogeneous systems and through colloids.—Chapter 5 is devoted to the permeability of non-living membranes. Differential permeability is discussed in some detail, along with the theories to account for the facts.—Chapter 6 deals with osmotic pressure: its determination, relation to temperature and concentration and measured values in sucrose; electrolytes and colloids; theories of osmotic pressure; and negative osmosis and its explanation.—Chapter 7 deals with the structure and composition of the cell wall, and with semi-permeable cell walls.—Chapter 8 is devoted to the plasma membrane. The 5 lines of evidence for its existence are considered: the physical laws of surfaces, cytological observations, the water relations of the cell, selective permeability and allied phenomena, and electrical conductivity. The composition of the limiting protoplasmic layer and the thickness of the plasma membrane also receive attention. Other cell membranes are mentioned.—*I. F. Lewis.*

1412. VERZAR, F., und R. BECK. Die Änderung der Aussalzbareit von Bakterien der Typhusgruppe durch verschiedene Verhältnisse. [The salting out of bacteria of the typhus group as affected by various means.] *Biochem. Zeitschr.* 107: 81-97. 1920.—Cultivation of bacteria of the typhus and para-typhus groups in agglutinin-containing bouillon failed to induce a spontaneously agglutinating type or to increase the sensitivity to sodium chloride or ammonium sulphate. Only a decrease in agglutinability resulted from cultivation in immune serum, the decrease being less in concentrated than in dilute serum for typhus bacilli, but considerable in the case of para-typhus B bacilli grown in concentrated serum. A manifold difference was shown between salting out by ammonium sulphate and agglutination by specific agglutinins.—*H. D. Hooker, Jr.*

1417. MENDIOLA, N. B. Effect of different rates of transpiration on the dry weight and ash content of the tobacco plant. *Philippine Jour. Sci.* 20: 639-655. 1922.—The study of plants grown in water culture shows that there is no absolute correlation between the percentage of ash, the relative rates of transpiration, and the total dry matter.—*E. D. Merrill.*

MINERAL NUTRIENTS

1418. ARMSTRONG, GEORGE M. Studies in the physiology of the fungi. XIV. Sulphur nutrition: the use of thiosulphate as influenced by hydrogen-ion concentration. Ann. Missouri Bot. Gard. 8: 237-281. Fig. 1-21. 1921.—*Aspergillus niger*, *Penicillium glaucum*, and *Botrytis cinerea* have been shown to utilize the following chemicals as sources of sulphur; MgSO_4 , $\text{Na}_2\text{S}_2\text{O}_3$, MnSO_4 , KSH, KHSO_3 , $\text{K}_2\text{S}_2\text{O}_8$, KCNS, and NH_4CNS . Some growth was evidenced with K_2S . The production of H_2S , occurring except where MnSO_4 , MgSO_4 , and $\text{K}_2\text{S}_2\text{O}_8$ were used, seems not related directly to active acidity strength of the solution or relative degree of growth. The action of the fungi on $\text{Na}_2\text{S}_2\text{O}_3$ produces sulphates in the culture solution. Other forms of sulphur as end-products are H_2S , molecular sulphur, tetrathionate, and globules of sulphur sometimes found in the hyphae.—For cultures of *Aspergillus niger*, *Penicillium cyclopium*, and *Botrytis cinerea*, the ratio of thiosulphate decomposition to growth is not constant, although for some fungi this is true. Active acidity does not appear to influence the utilization of sulphur from thiosulphate.—In a modified Pfeffer's solution the reaction reverses for *Aspergillus niger* when the sugar disappears, while *Penicillium cyclopium* may cause a reversal of the reaction with sugar present in the solution. Since it has been established that reversal of the reaction may occur, it is clear that the true course of the changes which have occurred may not be obtained merely by a determination of the initial and final H-ion concentration of the fungous cultures.—S. M. Zeller.

1419. GARNER, W. W., J. E. McMURTREY, and E. C. MOSS. Sand drown, a chlorosis of tobacco and other plants resulting from magnesium deficiency. Science 56: 341-342. 1922.—This chlorosis attacks plants on sandy soil in wet seasons. Field and laboratory study has shown it to be due to lack of magnesium and it is aggravated by the presence of much sulphur. The leaf is blanched as a whole. Tests seem to show the importance of proper fertilizers but only 50 pounds of magnesium are actually needed per acre.—C. J. Lyon.

1420. GUILLAUMIN. Quelques expériences sur la fertilisation préalable des semences. [Some experiments on the preliminary fertilization of seeds.] Rev. Gén. Bot. 34: 257-263. 1922.—Experiments were made with barley and radish seed, dipping them for varying lengths of time in water and in solutions of ammonium nitrate and peptonate of gelatin. Dipping in water favored and hastened germination. The effect of dipping seed in fertilizing solutions differs with the plant used and the strength of solution employed. With 4 per cent solutions of nitrate of ammonia germination of radish seed was injured if the dip lasted 1 hour or longer. With 4 per cent peptonate of gelatin no appreciable effect was observed for the same durations of dipping.—With very weak solutions of nitrate of ammonia, germination was hastened and the yield of radishes was increased following short durations of dipping.—The peptonate of gelatin hastened the germination of barley noticeably, but it lowered the yield of radishes even with a very short interval of dipping, although increasing the production of chlorophyll.—J. C. Gilman.

1421. MAQUENNE, L., et E. DEMOUSSY. Influence des matières minérales sur la germination. [The influence of mineral materials on germination.] Ann. Sci. Agron. Française et Étrangère 38: 113-151. 1921.—Claiming that the distilled water and cultural media, such as paper, cotton, moss, ordinarily used by plant physiologists contain sufficient mineral matter to render invalid experiments as delicate as those herein reported, the authors describe their own technique. The water was twice distilled from Jena glass fitted with a quartz condenser, and kept in vessels of quartz or platinum; as media purified quartz sand and quartz tubes were used. The experiments were as follows: (1) The influence of 12 salts, used singly on germination of peas. These included the sulphates and chlorides of the alkali metals, the alkaline earth metals, also zinc, manganese, aluminum, lead, and copper. Calcium sulphate was most beneficial and copper sulphate most toxic. (2) The effect of different metals in the presence of calcium. The results show that the favorable action of calcium is considerably weakened by the presence of another salt. (3) The influence of acids on the germination of peas and wheat. Up to a concentration of 0.5 mgm. per 10 cc. the acids were favorable; be-

yond that, unfavorable. (4) The influence of salts of iron on germination. Ordinary ferrous sulphate or ferroso-ammonium sulphate was used as the ferrous, and ammonium iron alum as the ferric salt. In 1 experiment colloidal ferric oxide, prepared by dialysis of the chloride, was used. It was found that ferrous salts are much more toxic than either the ferric salts or colloidal ferric oxide, the latter giving slightly better growth than the ferric salt. Calcium sulphate was antitoxic to ferrous salts and, reciprocally, ferrous sulphate decreased the beneficial effect of calcium sulphate.—Extensive experiments with copper sulphate are reported. Employing a very sensitive colorimetric method, copper was found to be present in a great number of soil samples of diverse origin, arable soils containing ordinarily not more than 10 mgm. per kgm; soils from vineyards ran exceptionally high, some as much as 200–300 kgm. of metallic copper per hectare,—12–14 cm. deep,—these excessive amounts being due to long continued use of copper fungicides. Practical experience shows that this large amount is not toxic but, on the contrary, is probably antitoxic.—Copper was also found to be present in various parts of all of a number of species of plants examined; and since it prevails especially in parts of greatest growth activity it is considered indispensable to protoplasm.—With peas CaSO_4 is antitoxic for CuSO_4 and the latter antitoxic for iron salts. The last mentioned result is ascribed to the oxidative (catalytic) action of copper, since infinitesimal amounts sufficed to accelerate the oxidation of iron and render it insoluble or colloidal.—A. B. Beaumont.

1422. MEVIUS, WALTER. Beiträge zur Physiologie "kalkfeindlicher" Gewächse. [The physiology of calciphobous plants.] Jahrb. Wiss. Bot. 60: 147–183. 1921.—No harmful effects due directly to calcium were noted upon the growth of *Sphagnum rufescens*, *S. fimbriatum*, *S. imbricatum*, and *S. quinquefolium*. CaCO_3 caused injury and death of *Sphagnum* because of its alkaline reaction. When the free alkali is neutralized no such injury occurs. Phosphates caused injury, but their poisonous action could be corrected by KNO_3 and MgSO_4 . Calcium was found to be unquestionably necessary for the growth of *Pinus Pinaster* and *Sarothamnus scoparius*; the lack of calcium caused the roots of the latter to rot, and it resulted in shoot-tip injury to the former. The behavior of both these plants toward OH ions was similar to that of *Sphagnum*. In strong concentrations these ions caused a great decrease in growth and a destruction of roots in both plants. Weak concentrations caused chlorosis. The concentrations causing definite injury were different for each species.—A bibliography of 62 titles is appended.—Earl S. Johnston.

1423. MUENSCHER, WALTER C. The effect of transpiration on the absorption of salts by plants. Amer. Jour. Bot. 9: 311–329. 1922.—Previous work on this subject is outlined and the many contradictory results and conclusions noted. The author studied transpiration in a pure line of barley, grown in Knop's solution in a greenhouse, one series of experiments being conducted in the summer and another in the winter. Cultures were grown for 5 weeks, the solution being changed every 5th day. Green weight, dry weight, and ash weight for tops and roots were determined. In the summer series the rate of transpiration was modified by changing humidity and light, plants being grown under 4 conditions, namely, in a dry chamber, in a humid chamber, in the sunlight, and under a shade tent. In the winter series, transpiration was modified by shading and by changing the concentration of the solution, plants being grown under 3 conditions, as follows: in sunlight in dilute solution, under a shade tent in dilute solution, and in sunlight in concentrated solution. When transpiration was reduced to less than half by increasing humidity, total ash content of plants remained essentially the same. Shading reduced transpiration but reduced photosynthetic activity also, and therefore total ash content. Increased concentration of nutrient solution reduced transpiration markedly but ash content hardly at all. The ash content expressed in percentage of total dry weight of the whole plants varied but slightly, regardless of whether the plants were grown under conditions of high or of low transpiration and irrespective of how transpiration was reduced. These results show that there is little or no relation between transpiration and absorption of salts in barley and they do not support the theory that transpiration plays an important rôle in supplying the plant with nutrient salts. The amount of growth seems to be an important factor in determining the amount and rate of entrance of essential salts taken up.—E. W. Sinnott.

1424. TRUOG, E. The feeding power of plants. *Science* 56: 294-298. 1922.—It has been proved that roots do not make mineral nutrients available primarily by acid excretion nor by the acid condition of the root hairs in contact with the soil. If 2 soluble products are formed by the excreted carbonic acid, the utilization is dependent upon the removal of these products. Plants with a high calcium content utilize rock phosphate because they remove the phosphate and calcium bicarbonate. Similar explanations may be given for the use of calcium, potassium, and base-forming elements, such use being related to sap acidity.—C. J. Lyon.

1425. WESTER, D. H. Over het mangengehalte von bloemen. [The manganese content of flowers.] *Pharm. Weekblad* 59: 51-55. 1922.—The flowers of 34 species of plants were examined and it was found that the moisture of the petals varies between 75.6 per cent in *Senecio Jacobaea* and 94.5 per cent in *Clivia*; generally 80-90 per cent of moisture is present. The smallest amount of ash was found in the petals of *Rhododendron* and the highest in the petals of chervil. The ash usually amounts to 1 per cent in the petals of flowers. All the flowers contained manganese, from 0.92 mgm. in 100 gm. of dry petals in *Weigelia* to 14.5 mgm. in *Melampyrum*. Expressed in mgm. of Mn in 100 gm. of ash the lowest amount, 11.2 mgm., was found in *Lamium* and the highest, 222.1 mgm., in *Centaurea*.—H. Engelhardt.

1426. WINSLOW, C. E. A., and MARGARET HOTCHKISS. Studies on salt action. V. The influence of various salts upon bacterial growth. *Proc. Soc. Exp. Biol. and Med.* 19: 314-315. 1922.—The effects of the addition of various salts to peptone solution containing *Bact. communis* were studied. It was found that there is a definitely stimulating action exerted by concentrations of salts below the inhibitive level.—M. M. Brooks.

1427. WRANGELL, M. VON. Gesetzmässigkeiten bei der Phosphorsäureernährung der Pflanze. [The laws governing the phosphorus nutrition of plants.] *Landw. Jahrb.* 57: 1-78. 1922.—As a result of a detailed study of the influence of phosphatic fertilizers on plant growth the author comes to the following conclusions: (1) Different plants do not utilize alike the difficultly soluble calcium phosphates. (2) The calcium-loving plants are able to utilize phosphoric acid from difficultly soluble calcium phosphates (raw phosphate, tricalcium phosphate) even when the reaction is weakly alkaline. The presence of moderate quantities of alkaline or physiologically alkaline calcium salts prevents appreciably the high calcium consumption of these plants, but not the utilization of the calcium phosphate. Other plants, particularly cereals, utilize difficultly soluble calcium phosphates only in the presence of acid manures, or when the soil reaction is acid. With manures reacting alkaline, and in the presence of lime, the acidity of the soil is diminished and the utilization of calcium phosphates ceases completely. (3) The ratio $\text{CaO} : \text{P}_2\text{O}_5$ in the ash of these plant groups is distinctly different. In the cereals, the calcium-phosphoric acid factor (ratio of molecular $\text{CaO} : \text{molecular P}_2\text{O}_5$) is, on the average, 1 to 3; in the calcium-loving plants (Cruciferae, beets, flax, buckwheat), the ratio is much larger, on the average 15. This factor indicates the ability of various plants to utilize difficultly soluble calcium phosphates. (4) The greater the calcium consumption of plants, the longer is the absorption of phosphoric acid from calcium phosphate prevented by the presence of calcium salts. Cereals containing normally, in the ash, less calcium in relation to P_2O_5 than would correspond to the formula $\text{Ca}_3(\text{PO}_4)_2$, can utilize the latter only in the absence of other calcium salts. In the presence of 1 molecule of CaCO_3 for 1 molecule $\text{Ca}_3(\text{PO}_4)_2$, the yield of oats diminished to $\frac{1}{2}$; with 2 molecules CaCO_3 , to $\frac{1}{3}$; in the presence of 5 molecules of CaCO_3 , the $\text{Ca}_3(\text{PO}_4)_2$ was not utilized at all. This drop in the utilization of $\text{Ca}_3(\text{PO}_4)_2$ by increasing the amount of CaCO_3 , was much slower in the case of buckwheat. Only in the presence of 600 molecules of CaCO_3 had the calcium-phosphoric acid ratio reached a maximum, and the action of $\text{Ca}_3(\text{PO}_4)_2$ ceased completely. The ability of plants to assimilate calcium is in a way a measure of the calcium-phosphoric acid factor. (5) In the presence of pure $\text{Ca}_3(\text{PO}_4)_2$ in neutral, calcium-free sand, white mustard will suffer from lack of calcium, while corn will suffer from lack of phosphoric acid, as seen from the ash analyses. White mustard gives, under these conditions, a relatively high P_2O_5 content with a low calcium content (factor 7 instead of the normal factor 15). Corn shows a low P_2O_5 and a high Ca content (factor 16

in comparison with the normal 3). The calcium-phosphoric acid factor can serve as an index of the conditions under which plant nutrition takes place, giving information on the soil reaction, $\text{Ca}:\text{P}_2\text{O}_5$ ratio in the soil, degree of activity of these substances, etc. (6) Pot experiments as well as practical field conditions may in some cases show a lack in a certain nutrient, while the soil itself may actually not need this nutrient. This may be due to the other fertilizers used, soil reaction, and presence of an abundance of lime. (7) The sensitiveness of lupines towards calcium can be overcome by an excess of P_2O_5 fertilization. (8) In general an acid reaction in the soil favors an anion assimilation, while an alkaline reaction favors an assimilation of cations. (9) In the presence of soluble phosphates, particularly acid phosphates, there is abundant development of the green flagellated alga *Haematococcus pluvialis*, on the surface of the sand; in the absence of P_2O_5 , there is a development of the red palmella form of the same species; in the presence of difficultly soluble phosphates with reaction acid, or CaHPO_4 with reaction alkaline, both the red and green forms or mixed forms develop side by side. (10) The utilization of tertiary aluminum and iron phosphates by different plants is not dependent on the presence of calcium and its action. These phosphates are utilized relatively well, specially magnesium phosphate. (11) The question of the kind of base in phosphatic fertilizers is important. The utilization of the phosphates Ca, Al, Fe, and Mg depends on the preference of the individual plants for the corresponding base.—*Selman A. Waksman*.

PHOTOSYNTHESIS

1428. BALLY, E. C. C. Photosynthesis. *Nature* 109: 344-346. 1922.—All chemical reactions are considered to take place in 3 stages: (1) changing the molecules from an inactive state into the reactive condition, either by a catalyst or by absorption of radiant energy; (2) the actual atomic rearrangements by which the new compounds are formed; (3) the changing of the resulting molecules into the normal inactive state. The energy used in stage 1 may be greater than that evolved in 2 and 3 (endothermic reaction) or less (exothermic reaction). Highly endothermic reactions, such as the production of formaldehyde from carbon dioxide and water, require so much energy that as a practical laboratory method heat energy cannot be used, while ultra-violet light of 200 micromillimeters wave length can be. Basic dye stuffs, as malachite green, methyl orange, or *p*-nitrosodimethylaniline, in a solution of carbon dioxide will act in ordinary daylight as photocatalysts in producing formaldehyde; and chlorophyll in plants seems to act in this manner. The formaldehyde thus produced, being in a reactive condition, does not require added energy to activate it; and since it has been shown that formaldehyde in this condition will polymerise to a reducing sugar, it is believed that this accounts for sugar production in leaves and the lack of free formaldehyde. As for the oxygen, "it is in the highest degree probable that a molecule of chlorophyll *a* combines with a molecule of carbonic acid, and this complex on exposure to light gives a molecule of activated formaldehyde and a molecule of chlorophyll *b*, which by another mechanism in the leaf is changed back to the *a* form, thus releasing a molecule of oxygen. It is further suggested that carotin has the power of reducing chlorophyll *b* to chlorophyll *a*, being itself oxidized to xanthophyll," since the ratio of xanthophyll to carotin increases during photosynthesis. The 2 latter pigments may absorb sufficient energy to cause the evolution of oxygen. The sugars produced from activated formaldehyde are all hexoses which thus seem to be the starting point for the synthesis of other plant products. Further, activated formaldehyde will combine with potassium nitrate or nitrite in aqueous solution in ultra-violet light, and when in excess both sugars and the form-hydroxamic acid are formed independently. This is suggested as the condition in plants. Ammonia also combines readily with activated formaldehyde. "Finally, one very important deduction may be made. The sole photosynthetic process in the living plant would seem to be the production of activated formaldehyde from carbon dioxide and water" and all other processes are essentially polymerisations or chemical syntheses.—*Ernest Shaw Reynolds*.

1429. BALLY, E. C. C., I. M. HEILBRON, and D. P. HUDSON. Photocatalysis. Part II. The photosynthesis of nitrogen compounds from nitrates and carbon dioxide. *Jour. Chem. Soc. [London]* 121: 1078-1088. 1922.—This is a discussion of the formation of the complex nitrogen

derivatives in plants, based on experiments in which nitrogen compounds were synthesized in vitro from carbon dioxide and potassium nitrate. The activated formaldehyde, photo-catalytically formed in leaves from carbonic acid through the agency of chlorophyll, reacts with potassium nitrite to produce form-hydroxamic acid, the 1st step in the synthesis of nitrogen compounds in plant tissue. Form-hydroxamic acid reacts with additional activated formaldehyde producing more complex nitrogen-containing substances known to occur in plants, e.g., amino-acids, alkaloids, etc. Any excess of activated formaldehyde condenses to hexoses (but not to pentoses). In these various nitrogen reactions oxygen is evolved. It is believed that nitrogen synthesis takes place exclusively in leaves, and that the products are transported as soluble glucosides. These results explain the observations of Schimper [Bot. Zeitg. 46: 65. 1888] to the effect that nitrites are always present in the leaf in the dark and that they disappear when the leaf is exposed to light. The activated formaldehyde formed in the light reacts with the nitrites, forming other nitrogen compounds. It is suggested that catalase is involved in the reduction of nitrate to nitrite. Readiness of reaction in these syntheses is explained by the highly activated condition of the compounds. "The key to the problem is the enhanced reactivity of freshly synthesized molecules."—*F. E. Denny.*

1430. WARBURG, O. Über die Geschwindigkeit der photochemischen Kohlensäureversetzung in lebenden Zellen. II. [The velocity of the photochemical decomposition of carbon dioxide in living cells.] Biochem. Zeitschr. 103: 188-217. Fig. 1-3. 1920.—When a dark-adapted green cell was illuminated at low intensity, no photochemical induction was detected; when illuminated at high intensity, the velocity of carbon assimilation increased in a few minutes to a constant end value. When a light-adapted cell was darkened, assimilatory activity diminished gradually and dark equilibrium was reached in 5 minutes. Narcotics affected carbon assimilation at low concentrations of CO₂ in the same manner as at high concentrations. Hydrogen cyanide retarded the photochemical cleavage of oxygen from CO₂ but not from intermediary products of respiration. Assimilation is thought to consist of 3 photochemical processes. The primary reaction affects chlorophyll but does not lead to the formation of oxygen. Another is the formation of acceptors from carbon dioxide, an irreversible reaction retarded by small amounts of hydrogen cyanide. Finally, the products of the 1st reaction react with the acceptors, a reaction not affected by hydrogen cyanide. Experiments on the photochemical reduction of nitrate in the absence of CO₂ failed to show whether the nitric acid was reduced directly or whether it reacted with cell constituents and the oxygen was produced in the same manner as during assimilation.—*H. D. Hooker, Jr.*

METABOLISM (GENERAL)

1432. BELL, MARION, and LAFAYETTE B. MENDEL. The distribution of vitamin-B in the wheat kernel. Proc. Soc. Exp. Biol. and Med. 19: 395. 1922.—Various percentages of wheat and wheat derivatives were fed to mice. From 14 to 40 per cent of the entire wheat kernel as a source of vitamin-B was required to insure normal rate of growth. Various parts of the grain itself were analyzed for the presence of vitamin-B.—*M. M. Brooks.*

1433. CIAMICIAN, G., and A. GALEZZI. Sul contegno di alcune sostanze organiche nei vegetali. [Upon the behavior of some organic compounds in plants.] Gazz. Chim. Ital. 52: 3-20. 1922.—The paper is divided into 3 parts: I. The attack of uric, dimethyluric, salicylic, *m*-cresylic, tetra-hydrophthalic, carboxypyrrolic, di-methyl-pyrrol-di-carbonic, phthalic acids, methyl salicylate, α -naphthylamine, pyridine, quinoline, urea, guanidine, eugenol, vanylline of benzilic acid and alcohol by the pulp of *Spinacia oleracea* in oxygen and toluol. II. A study of the attack of glucosides by the leaves of the cherry laurel and *Spinacia*. The following substances were studied: amygdaline, salicine, saligenine, tannin, and pyrogallol.

III. A study of the effect of xanthine, theobromine, caffeine, compound esters (diethyl oxalate and succinate vs. the K salts), monovalent alcohols (methyl, ethyl, propyl, isopropyl, isobutyl, isoamyl) aldehydes (formic, acetic, and propionic), ketones, and oxyacids upon the growing plant of *Phaseolus*. The technique has been previously described. [See also Bot. Absts. 5, Entry 2240; 6, Entry 1317; 7, Entries 2133, 2134; 10, Entries 1341, 1342, 1361].—A. Bonazzi.

1434. COLIN, H. L'inuline dans les plantes greffées. La greffe soleil annuel-Topinambour. [Inulin in grafted plants. The sunflower-artichoke graft.] Rev. Gén. Bot. 34: 145-155, 202-213. 1922.—The graft of sunflower (*Helianthus annuus*) and artichoke (*Helianthus tuberosus*) was studied with particular regard to chemical characteristics of the sap of the grafted plants. The carbohydrates of the sunflower are saccharose and the reducing sugars, chiefly glucose; those of the artichoke are inulin and its derivatives. From chemical analyses of both autonomous plants and of grafts of sunflower on artichoke and vice-versa the author concludes that the different plants making up the graft maintain their individual identities and do not fuse either physiologically or morphologically.—J. C. Gilman.

1435. DEUSSEN, E. Die Gramsche Bakterienfärbung, ihr Wesen und ihre Bedeutung. [The nature and significance of Gram staining.] Biochem. Zeitschr. 103: 123-141. 1920.—The effect of various acids at different temperatures in rendering Gram-positive yeast Gram-negative was determined. This change, which was in proportion to the degree of dissociation of the acid, is attributed to an alteration of the cell contents. It is suggested that the tendency of acids and neutral salts to reduce and eventually to stop the fermentation of sugar by yeast may be attributed to protein precipitation within the cells. A similar effect is surmised to be produced in *Staphylococcus aureus*.—H. D. Hooker, Jr.

[The rôle of acids in carbohydrate metabolism. V. The action of acids and alkalis upon the carbohydrate metabolism of the yeast cell.] Biochem. Zeitschr. 127: 1-12. 1922.—As a means of interpreting previous experiments on glycogen formation in liver, the writers have studied the effect of acid and alkaline solutions on the content of this carbohydrate in yeast. Methods are briefly described. The quantitative sugar data were obtained after hydrolysis by the Bertrand method. Acid solutions showed no consistent effect upon glycogen content. In alkaline solution, however, a definite increase in glycogen content was correlated with increased solution concentration up to $\frac{N}{20}$ NaOH. At greater concentrations (up to $\frac{N}{5}$) there was increase in total glycogen, most of which was present in the surrounding solution. An increase in total carbohydrate content is ground for the conclusion, supported by nitrogen determinations ("Rest" N), that increase in glycogen does not result from conversion of existing sugars, but from the clearance products of proteolysis.—W. W. Bonns.

1440. MACDOUGAL, D. T. The probable action of lipoids in growth. *Proc. Amer. Phil. Soc.* 61: 33-52. *Fig. 1.* 1922.—Experiments performed are for the consideration of lipoids as a fundamental structure of protoplasm and the primary factor in all exchanges between the cell and the medium. Measurements of endosmose in artificial cells with a plasmatic lining including lipoids were made. The porosity of the clay walls was first determined in various ways and then the absorption capacity of lining layers of various mixtures of biocolloids measured when under the influence of salts, saponin, and soaps. Lecithin incorporated in the plasmatic jelly layer of the cell had little effect on the osmotic action, but when deposited as a layer between the plasmatic jelly and the outer wall it lessened the permeability and increased the osmotic effect. The use of saponin or solutions which liquefy or displace lecithin in the cell contents or external layer increased permeability by increasing hydration, and lessened osmotic action. The hydration reactions of living and dead cell masses in the solutions used in the osmotic tests showed a similar influence on the wall of the plant cell. Variations in thickness indicative of changes in turgidity of cell masses subjected to neutral salts and other solutions were registered by means of the auxograph.—*Wanda Weniger.*

1441. MOREAU, M. et MME. FERNAND. Étude des phénomènes sécrétoires dans les glandes à lupuline chez le houblon cultivé. [Study of the secretion of lupulin by the glands of cultivated hops.] *Rev. Gén. Bot.* 34: 193-201. *Pl. 9-10.* 1922.—During the development of the lupulin-glands, 3 groups of substances may be recognized in the cells: lipoids, tannoids, and the essences and resins. A special procedure was used in the case of the lipoids due to their solubility in alcohol, benzine, toluene, xylol, or other substances used in fixation and imbedding. During the growth of the gland the lipoids were observed in the cytoplasm in the form of granules and filaments, present from the beginning, becoming more and more abundant up to the time of the spreading of the disk and cup, then diminishing in quantity in the later stages. The tannoids on the other hand occur in the vacuoles. They are present in solution in the young stages, then appear as threads or a network, later becoming more voluminous, and they persist even in the older glands. The essences and resins were not found in the young glands, which were rich in lipoids but they became abundant in the later cup stage. These products are present in the cytoplasm between the vacuoles containing the tannoids or around the large tanniferous central vacuole, always as globules larger than the granular lipid bodies. Because of these associations the authors are inclined to consider that the essences and resins are elaborated from the lipoids or, if the relation is not so close as this, at least the lipoids react with the protoplasm to modify permeability so as to allow the passage of the essences and resins into the subcuticular cavity of the gland.—*J. C. Gilman.*

1442. NEUBERG, C. Weitere Erfahrungen über die Bildung und Bedeutung der Fructose-diphosphorsäure im Stoffwechsel der Hefe. [The formation and significance of fructose-diphosphoric acid in yeast metabolism.] *Biochem. Zeitschr.* 103: 320-335. 1920.—Since fresh bottom yeast in the presence of toluol contains no hexose diphosphate, while the same yeast when dried contains it, this compound appears, in a sense, as a pathological product of yeast metabolism. It is not considered essential to the process of fermentation, as sugar was decomposed without any indication of esterification.—*H. D. Hooker, Jr.*

1443. NORD, F. F. Phytochemische Reduktion von o-Nitrobenzaldehyd. [Phytochemical reduction of o-nitrobenzaldehyde.] *Biochem. Zeitschr.* 103: 315-319. 1920.—The action of yeast cells on ortho-nitrobenzaldehyde results in the recovery of only 10 per cent as ortho-nitro-benzylalcohol. Other reaction products are present. The phytochemical reduction of the aldehyde groups is evidently easier than that of the nitro group.—*H. D. Hooker, Jr.*

1445. ROSE, MARY SWARTZ, AND GRACE MACLEOD. The almond as a source of the A vitamin. *Proc. Soc. Exp. Biol. and Med.* 19: 391-393. 1922.—When 3 per cent almond mixture

was added to the basal diet of rats, their weight increased. This shows that almonds seem to be fairly rich in fat-soluble A vitamin. Larger quantities produce unfavorable effects on growth.—*M. M. Brooks.*

1446. SAHA, HARIDAS, AND KUMUD NATH CHOUDHURY. **Capsularin, a glucoside from jute leaf.** Jour. Chem. Soc. [London] 121: 1044-1046. 1922.—The glucoside capsularin was isolated from the leaves of the jute (*Corchorus capsularis*) and was found to differ from the glucoside corchorin present in the seed of the same plant. A purified, crystalline product was obtained. On hydrolysis *d*- and *l*-glucose were split off, but the identity of the second product of hydrolysis was not established.—*F. E. Denny.*

1447. WILLAMAN, J. J., AND R. M. WEST. **Correlations among the constituents of potato tubers.** Proc. Soc. Exp. Biol. and Med. 19: 360-362. 1922.—The protein and carbohydrate found in potato tubers are not correlated with the dry matter, but are correlated with each other negatively. The amount of ether extract found in tubers is insufficient to account for all the increase in dry matter. It is possible to improve the potato tuber as regards protein, provided the dry matter is increased, thereby maintaining the mealiness which is a desirable quality.—*M. M. Brooks.*

1448. WISLICENUS, H. **Die Kolloidchemie des Holzes, seiner Bestandteile und seiner Entstehung.** [The colloid chemistry of wood, its components and its formation.] Kolloid Zeitschr. 27: 209-223. 1920.—Ordinary chemistry, although showing the method by which even the large molecules of tannins, fats, and resins may be formed from the simpler photo-synthetic products, fails to explain lignification. Although cellulose is constant in composition, with the formula $(C_6H_{10}O_5)_x$ (x being large) lignin has a carbon content varying from less than 52.5 to over 65.0 per cent; hydrogen ranges from 5.3 to 4.8 per cent; while oxygen and nitrogen together range from 30.2 to 42.2 per cent. Klason's formula $(C_{40}H_{42}O_{11})$ really applies to an aromatic component of lignin. The stainable substances in lignified wood are not lignin. Lignin is the sum of all colloiddally dissolved hydrosols of high molecular weight that are deposited from the formative or cambial sap upon the surface of cellulose fibers. Anatomical variability of tissues and vessels of woody plants is not very great and depends upon differences in surface structure, i. e., upon the variability of lignin, and on it also depend the properties, density, etc., of wood.—The author's hypothesis involves many considerations, thus (1) an increasing complexity of sap compounds as the leaf activity proceeds, also the transportation and concentration of these in the older cells as oxidation and condensation products; (2) the ascending transpiration stream, laden with salts, etc., meeting the stream of assimilate and inducing coagulations and other colloid chemical effects; and (3) the indifferent hydrosols being coagulated by the multivalent ions, the acid substances with high molecular weight forming alkali salts and thus acquiring greater dispersion and dissemination.—The author then used cambial sap and spring root sap in testing for strongly dispersed, weakly adsorbing substances and for those that were but slightly dispersed and were strongly adsorbent. The inner bark was peeled off with glass or porcelain and put at once into distilled water to prevent discoloration through oxidation. This was filtered and quantitative studies on adsorption were undertaken. Spring bleeding sap contains but little colloid at the beginning and from March to the end of sap flow (near May 1) shows only a slight increase—to 4.5-8.5 per cent. The hornbeam, which forms especially heavily lignified wood, had 21 per cent by May. The cambial sap from the beginning of leaf activity was, however, very rich in colloids. In May, June, and July the percentage of colloids was from 30 to 40 per cent. About the beginning of August it drops to its low point, 6.5-8.0 per cent, or about the amount in bleeding sap. About this time secondary thickening ceases and the cortex dries. At the time of maximum wood formation the colloid content of the leaf sap is the highest. When wood formation is at its minimum, the colloid content is likewise.—The pure chemistry is not clear. The chief possibilities are: (1) normal polymerization and addition by main valences; (2) molecular complex formation by sub or latent valences; (3) ordinary condensation; (4) autooxidation with following condensation; (5) independent syntheses and transformations. Examples of these various

classes are discussed from the standpoint of the application to lignification. It is possible to form a cellulose hydrosol by grinding cellulose fibers in water for a long time; upon standing this sol stiffens to a jelly. The similarity of fibrous clay in structure and in adsorption behavior to animal and plant fibers is pointed out and illustrated by photomicrographs. After its deposition various adsorptive changes take place in lignin and these are followed by slow chemical transformations and greater concentration of molecules, especially of the carbinol groups of the saccharide polyalcohols. This leads to aging, and with drying, the mass becomes so resistant that few chemical reagents are able to affect it.—*H. E. Pulling.*

METABOLISM (NITROGEN RELATIONS)

1449. FODOR, A. Studien über den Kolloidzustand der Proteine im Hefeauszug. 1. Hefesaftprotein in alkalischer Lösung. Beziehungen zu biologischen Vorgängen. [The colloidal condition of the proteins in expressed sap of yeast. 1. Yeast-sap protein in alkaline solution. The relation to biological processes.] *Kolloid Zeitschr.* 27: 58-69. 1920.—Because the enzymatic action is best in weakly alkaline solution and because there is an adsorption compound between the colloidal enzyme and its substrate, this research was undertaken as a basis for a theory of enzyme action in yeast. The ionic theory cannot explain the facts either of ferment action or of adsorption in these solutions without the help of dispersoid chemistry. The enzyme is the adsorbent to which the substrate is bound. The optimum concentration is the result of 2 opposing reactions of which one is an increase in the degree of dispersion through accumulation of OH ions, while the opposing action is produced by hydration of the enzyme particles, which thus decreases its power to adsorb substrate. The biologically active parts of peptolytic and tryptolytic enzyme systems are colloids in the state of heteroions that bear OH groups in a potential condition and which are not injured by extensive hydration and decrease in adsorbing power. Apparently the organism regulates the hydration by suitable acidity of the medium.—*H. E. Pulling.*

1450. GLÄSSNER, K. Eine neue Pepsinbestimmungs Methode. [A new method of pepsin determination.] *Biochem. Zeitschr.* 127: 312-315. 1922.—The method is based on the precipitation by dilute ammonia of globin in solution acidified by HCl.—*W. W. Bonns.*

1451. KNOWLTON, H. E. A preliminary experiment in half tree fertilization. *Proc. Amer. Soc. Hort. Sci.* 18: 148-149. 1921 [1922].—In an effort to obviate the factor of tree individuality an experiment was conducted whereby the root systems on one side of each of 25 Rome Beauty apple trees were fertilized with 5 pounds of nitrate of soda several weeks before blooming time and the other side of each left as control. At intervals after the application, samples of buds and leaves were taken from both sides of the tree. On the 5th and 8th days no noticeable differences were evident between the nitrogen content of the opening fruit buds on the 2 sides of the tree. On the 12th day the buds on the fertilized side showed 43.5 mgm. of nitrogen and on the unfertilized side 30.9 per gm. of dry weight. On the 21st day the corresponding analyses of leaves were 17.4 and 12.9 mgm. respectively. Analyses made in the fall showed no significant differences between the 2 sides. A study of terminal growths showed that limbs on the fertilized side received more nitrogen than did the unfertilized side.—*W. E. Whitehouse.*

1452. RAYNER, M. CHEVELEY. Nitrogen fixation in Ericaceae. *Bot. Gaz.* 73: 226-235. *Fig. 1-4.* 1922.—The author summarizes the investigations which furnish "cumulative evidence that the endophyte of Ericaceae can utilize atmospheric nitrogen in greater or less degree." Experimental evidence is given which supports the conclusions of Ternetz that the *Calluna-Phoma* symbiosis is an obligate one. The ericaceous plant in this instance to a significant degree obtains its nitrogen from the nitrogen-fixing fungus. This accounts for the "proved ability of a species such as *Calluna* and *Vaccinium* to thrive in soils deficient in nitrates."—*B. W. Wells.*

METABOLISM (ENZYMES, FERMENTATION)

1453. BIEDERMANN, W. Über die Wirkung von Pepsin und Trypsin auf Diastase. [The effect of pepsin and trypsin on diastase.] Biochem. Zeitschr. 127: 38-46. 1922.—These are experiments dealing with animal diastase (salivary excretions) showing that pepsin inhibits diastatic activity while trypsin does not.—W. W. Bonns.

1454. BOAS, F. Über die Abhängigkeit von Hefewachstum und Hefengärung von physikalisch-chemischen Erscheinungen. [The dependence of yeast growth and fermentation on physico-chemical processes.] Biochem. Zeitschr. 105: 193-198. 1920.—The fermenting ability of bottom yeast in 15 per cent glucose solution to which ammonium sulphate was added varied with the concentration of the latter, there being 1 maximum and 2 minimum zones, and the rate of growth showed 2 maxima and 1 minimum. Analogous results were obtained when racemic leucine, asparagin, and peptone were used as sources of nitrogen, the details varying with the strain of yeast used, but with natural leucine the carbon dioxide evolved was proportional to the concentration. The phenomena are attributed to physico-chemical changes in the plasma membrane.—H. D. Hooker, Jr.

1455. BOAS, F., H. LANGKAMMERER, und H. LEBERLE. Untersuchungen über Säurebildung bei Pilzen und Hefen. IV. [Acid formation by molds and yeasts.] Biochem. Zeitschr. 105: 199-219. 1920.—Acid formation by yeast was favored by the sugars maltose, glucose, fructose, and sucrose in increasing intensity, or inversely as they favored growth and fermentation, acid development being zero with many yeasts in maltose and very great in sucrose. The specific action of the sugar may be altered somewhat by adaptation, by the concentration of nitrogen, or by the reaction of the solution. Sucrose was inverted, but only slowly fermented. The nature of the nitrogen supply was immaterial, though with maltose ammonium chloride stimulated growth and fermentation more than asparagin. The maximum acidity attained during fermentation of sucrose was pH 2.44. In whortleberry juice with sucrose and ammonium chloride added, a pH of 1.85 was reached during vigorous fermentation, without injury to the yeast.—H. D. Hooker, Jr.

1456. HÄGGLUND, E. Schweflige Säure und Hefegärung. [Sulfurous acid and yeast fermentation.] Biochem. Zeitschr. 103: 299-305. Fig. 1-2. 1920.—The toxic action of sulfurous acid on yeast fermentation is ascribed to the undissociated molecule. Sodium sulphite also retards fermentation while potassium sulphate stimulates it, increasing it 25 per cent in a 0.2N solution.—H. D. Hooker, Jr.

1457. HEPBURN, J. S., E. Q. ST. JOHN, F. M. JONES, and W. F. BOKER. Studies of the North American Sarraceniaceae. Jour. Biol. Chem. 50: Proc. XLVI. 1922.—Liquor from closed pitchers of *Darlingtonia californica* contained diastase. Protease, maltase, emulsin, invertase, and urease were absent. Liquor from closed pitchers of *Sarracenia flava* contained invertase and lipase. Maltase, emulsin, diastase, urease, and esterase were absent. The liquor had a surface tension of 66.4 dynes per cm. Protease occurred in the fluid from closed pitchers of the Sarraceniaceae. Liquor from closed pitchers was bacterially sterile, that from open pitchers contained proteolytic bacteria. The pitchers absorbed nutrient compounds from their cavities. The pitcher liquor from the Sarraceniaceae produced permanent cessation of motion of ants and caused more of them to sink, and more promptly than in water. The rhizomes of the Sarraceniaceae did not contain protease.—G. B. Rigg.

Zeitschr. 106: 236-238. 1920.—The presence of methyl alcohol in fermented fruit juices is attributed to the hydrolysis of pectin, a methyl ester of pectic acid, and not to any process of fermentation.—H. D. Hooker, Jr.

1459. MERL, TH., und J. DAIMER. Studien über Mehlkatalase. [Studies of the catalases of flour.] Zeitschr. Untersuch. Nahrungs- u. Genussmittel 42: 273-290. 1921.—The behavior

of flour-catalase with trypsin is less conclusive in establishing that the former is of albuminous nature than is the case with animal catalases. A dried preparation of grain embryos (14 per cent of their original weight) possesses 5 times the catalytic power of the original material. The gas volumetric apparatus of Tillmans and Henblein was used for estimation of catalytic power. The optimum hydrogen-ion concentration extends from pH 6.2 to an alkaline reaction. The inhibitive action of acetic and lactic acids is weak. The optimum temperature is between 30 and 40°C., and the temperature coefficient of rapidity of decomposition is about 1.5. Relatively great resistance to dry heat, characteristically high susceptibility to moist heat, and a low resistance to high temperature in moist surroundings were demonstrated. In a comparison of inhibition by alcohol, benzol, chloroform, hydrocyanic acid, and toluol the last appeared least harmful.—*E. E. Stanford.*

1460. MORGULIS, S. The heat of enzyme reaction. A study of the heat produced in the catalase reaction. *Jour. Biol. Chem.* 50: Proc. XLII-XLIII. 1922.—The catalase reaction is exothermic and is accompanied by a definite heat production.—*G. B. Rigg.*

1461. NEMEC, ANTOINE, ET FRANÇOIS DUCHON. Sur la vitalité des graines et leur activité diastasique. [The vitality of seeds and their diastatic activity.] *Ann. Sci. Agron. Française et Étrangère* 38: 320-329. 1921.—Previously, it has been shown by the authors that diastatic activity diminishes with natural aging. In the researches here reported studies have been made of the activity of glycerophosphatase, lipodiatase, urease, amylase, catalase, and phytoprotease of various seeds compared with their more or less conserved vitality. The data submitted show that with some enzymes at least, the diastatic activity diminishes with increasing age of the seed. However, there are seeds which have lost their germinating capacity that still show a greatly lessened activity of certain enzymes; the activity of catalase seems to disappear almost entirely. From this the conclusion is drawn that it is the activity of catalase that represents the vitality of the seed. This relationship offers some practical possibilities for rapid detection of vitality of seeds, to be reported later by the authors.—*A. B. Beaumont.*

1463. NEUBERG, C., und MARTA EHRLICH. Über die Beziehung der phytochemisch reduzierbaren Substanzen zum Vorgange der alkoholischen Gärung und über die Natur der Aktivatorwirkung. [The effect of phytochemical reducing substances on alcoholic fermentation and the nature of the activation.] *Biochem. Zeitschr.* 101: 276-318. 1920.—Alcoholic fermentation of glucose is accelerated by naturally occurring ketones, diketones, and disulphides, as well as by aldehydes, but to a smaller degree. Phytochemical reduction seems to be correlated with the ability to stimulate alcoholic fermentation. The stimulating effect is accompanied by a reduction of the reducing group in the activator. The presence of acetaldehyde during ordinary yeast fermentation is thought to have biochemical significance.—*H. D. Hooker, Jr.*

1464. NEUBERG, C., und MARTA EHRLICH. Weiteres über die Beziehung der Aldehyde zur alkoholischen Gärung. [The effect of aldehyde on alcoholic fermentation.] *Biochem. Zeitschr.* 101: 239-275. 1920.—Experiments with 71 aldehydes show that alcoholic fermentation of glucose and mannose is furthered by the aldehyde group, the nature of the radical attached thereto having no appreciable influence. This acceleration occurs equally in fermentation by living yeast cells and in fermentation by enzyme preparations. It is shown by all manner of aldose sugars, whether they be fermentable or not.—*H. D. Hooker, Jr.*

1465. NEUBERG, C., und H. OHLE. Zur Kenntnis der Carboligase. III Mitteilung, Der Bau der biosynthetisch verknüpften mehrgliedrigen Kohlenstoffketten. [Carboligase. III contribution. The structure of the biosynthetic connected, multibranched hydrocarbon

chains.] *Biochem. Zeitschr.* 127: 327-339. 1922.—A report is made of further work with carboligase, an enzyme of yeast, in converting sugar or pyroracemic acid to phenylpyroracemic alcohol in the presence of benzaldehyde. Further treatment with organic reagents and with dilute H_2SO_4 results in a "biosynthesis" to 1-phenyl-acetyl-carbinol.—*W. W. Bonns.*

1466. NEUBERG, C., und E. REINFURTH. Ein neues Abfangverfahren und seine Anwendung auf die alkoholische Gärung. [A new procedure and its application to alcoholic fermentation.] *Biochem. Zeitschr.* 106: 281-291. 1920.—The intermediary production of acetaldehyde in alcoholic fermentation was demonstrated by the addition of dimethylcyclohexan-dione, 2 molecules of which condense with 1 of aldehyde with the elimination of 1 molecule of water. Sugars and ketones do not give the reaction. The same compound was obtained after fermentation with macerated yeast sap as with living yeast cells. Certain advantages of this procedure over the sulphite addition reaction are considered.—*H. D. Hooker, Jr.*

1467. NEUBERG, C., J. HIRSH, und E. REINFURTH. Die drei Vergärungsformen des Zuckers, ihre Zusammenhänge und Bilanz. [The three types of sugar fermentation.] *Biochem. Zeitschr.* 105: 307-336. 1920.—The 1st type of hexose fermentation yields alcohol and carbon dioxide; the 2nd acetaldehyde, carbon dioxide, and glycerol; the 3rd, acetic acid, alcohol, carbon dioxide, and glycerol. The 2nd type is considered primary, the carbon dioxide and acetaldehyde being derived from pyruvic acid. It is characterized by the amount of aldehyde fixed by sulphites as the bisulphite derivative. The 1st type is characterized by the amount of alcohol formed by reduction of acetaldehyde. In the 3rd type acetic acid and alcohol are formed from aldehyde by Cannizzaro's reaction, and the amount of acid or glycerol formed is characteristic. A quantitative cleavage of sugar to alcohol and carbon dioxide never occurs. When the 1st and 2nd types occur together the alcohol formed can be calculated as $46/90 (Z-180/92G)$ or $46/90 (180/44K-Z)$ where Z is transformed sugar; G , glycerol; and K , the total carbon dioxide produced. When the 1st and 3rd types occur together the amount of sugar fermented is: $(180A + 135G)/92$; or $180/92A + 135/30E$; or $90(K/44 + G/92)$ or $90(K/44 + E/130)$, where A is the total alcohol produced and E , acetic acid.—*H. D. Hooker, Jr.*

1468. OSTWALD, W. Zur physikalisch-chemischen Betrachtung der Gärungsvorgänge. [Physico-chemical consideration of fermentation.] *Biochem. Zeitschr.* 105: 305. 1920.—This is a reply to C. Neuberg [see Bot. Absts. 12, Entry 801].—*H. D. Hooker, Jr.*

METABOLISM (RESPIRATION, AERATION)

1469. FITCH, C. P. The cultivation of *Bact. abortus* Bang. *Proc. Soc. Exp. Biol. and Med.* 19: 414-415. 1922.—*Bact. abortus* was cultivated in the presence of 10 per cent hydrogen to show that diminished oxygen tension rather than any specific effect of CO_2 was responsible for the luxuriant growth of the organism.—*M. M. Brooks.*

1470. IRWIN, MARIAN, and MARGARET WEINSTEIN. Comparative studies on respiration XXI. Acid formation and decreased production of CO_2 due to ethyl alcohol. *Amer. Jour. Bot.* 9: 277-282. 2 fig. 1922.—By use of a previously described apparatus [see Bot. Absts. 10, Entry 291], the authors found that in radish seedlings ethyl alcohol decreases the production of CO_2 . At the same time, organic acids are produced, perhaps through the effect of the alcohol in accelerating the decomposition of certain substances and thus forming an excess of intermediate products in the form of acids. The fact that *Salvia* when treated with ether reacts in exactly the opposite manner, emphasizes the extreme complexity of the problems of respiration.—*E. W. Sinnott.*

1471. LANGWORTHY, C. F., and H. G. BAROTT. Heat elimination and gaseous exchange in grapefruit during storage. *Jour. Biol. Chem.* 50: Proc. XXXI. 1922.

1472. SMITH, EDITH PHILIP. Comparative studies on respiration XXII. The effect of lactic acid on the respiration of wheat. *Amer. Jour. Bot.* 9: 307-310. 2 fig. 1922.—In very

dilute solutions lactic acid first accelerates and then depresses the rate of production of CO_2 by wheat seedlings in water culture. As the concentration of the acid increases, this preliminary rise becomes less marked till a concentration is reached where the rate begins to fall at once. On removal to distilled water recovery is in time complete. Sulphuric acid and dextrose have practically no effect on rate of respiration and the observed results are therefore probably not due to osmotic pressure or H-ion concentration but to some specific action of lactic acid. It is concluded that since this acid does not cause a permanent increase in the rate of production of CO_2 , it is not an important intermediate substance in the metabolism of wheat.—*E. W. Sinnott.*

ORGANISM AS A WHOLE

1473. ABESAMIS, AMBROSIO P. Effect of time of planting on growth and yield of a lowland rice in Penaranda, Nueva Ecija, and on the college farm. *Philippine Agric.* 10: 381-392. 1922.—Time of transplanting and the amount of rainfall appeared to be very important factors in determining rice yield, high yields being correlated with large amounts of rainfall. Best cultures, which received about 1000 mm. of rainfall, gave a yield about 6 times as great as those which received less rainfall. Later maturity was also found to be correlated with greater amount of rainfall.—*Sam F. Trelease.*

1474. ARLOING, FERNAND, et LUCIEN THÉVENOT. Essais sur l'anaphylaxie chez les bactéries. Modifications produites par passages brusques dans les milieux de cultures bouillon-sérum à des taux différents. [Contributions to the study of anaphylaxis in bacteria. Modifications produced by abrupt changes in concentration of the bouillon-serum culture medium.] *Compt. Rend. Soc. Biol.* 87: 12-14. 1922.—Bacteria are very susceptible to sudden changes in composition of the medium and in consequence undergo modifications in their general biological characters. These changes are interpreted as being anaphylactic in nature, and involve the power of growth, virulence, and pigment formation of the bacteria.—*S. Morgulis.*

1475. CASELLA, DOMENICO. Studio sul polline delle piante da frutta. [The pollen of fruit trees.] *Staz. Sper. Agrarie Ital.* 54: 474-496. 1921.—The subjects studied are pollination; fruit formation; structure, form, color, and size of pollen grains of almond, peach, apricot, persimmon, pear, apple, grape, and mulberry; likewise the cultivation of the pollen in nutritive solutions, optimum sugar content of the germinating solution, types of germination, temperature relations, percentages of germination, and viability. The influence of germicidal substances on pollen germination and on fruiting are studied, as are also various teratological pollen forms. The conclusions are here summarized as follows: Pollination in the grape and mulberry is brought about by wind, whereas in the other plants studied (Rosaceae) it is brought about by insects. Rain, strong wind, and low temperature have a strongly deleterious influence on the process of pollination, whereas absence of rain and of fog, abundance of sunlight, moderate temperature, and a mild wind are advantageous. The form and size of pollen grains differ in the various species, varieties and even in individuals. The color varies in different genera. Saccharose in a concentration of 10-20 per cent is the best sugar for the germination of pollen. The pollen of grape is characterized by the formation of a small persistent bubble at the base of the pollen tube. Low temperatures interfere with germination and elongation of the pollen tube, whereas high temperatures accelerate the process. The optimum temperature is constant for each species and variety, as is also the percentage of germination. Pollen from diseased plants or branches has a lower percentage germination, while this power is slowly lost at a different rate in various varieties. With loss in germination capacity, not only a smaller percentage germinates, but the length of the germ tube is not as great as in normal pollen. Most germicidal substances (including sulphur) are deleterious to germination, even when applied directly to the plants during the flowering period. The same may be said for fruit inception. Abnormal types of germination are often observed.—*A. Bonazzi.*

1476. GERICKE, W. F. Certain relations between root development and tillering in wheat: Significance in the production of high-protein wheat. *Amer. Jour. Bot.* 9: 366-369. 1922.—More abundant tillering and culm production in wheat was obtained by the author in cultures

which received nitrogen comparatively late in the growing period than in those which received it at seeding, and he suggests that this may be due to differences in extent of root development at the time nitrogen was applied. He planted wheat seedlings, a few days old, in tap water where in 25 days they developed a large root system (presumably because of deficiency of nitrogen) but little new top growth. These seedlings were then placed in nutrient solutions, as was another set only a few days old, in which the tops were almost as large as in the first set but the roots only about $\frac{1}{4}$ as large. The set with the large root system developed more than 4 times as many tillers per plant as the one with the small system, presumably because of the larger absorbing area. Plants grown in nitrogen-poor soil similarly develop a large root system and when nitrogen is then added, absorb much more of this nutrient that is needed for normal growth, and abundant tillering results.—*E. W. Sinnott.*

1477. KNUDSON, LEWIS. Nonsymbiotic germination of orchid seeds. *Bot. Gaz.* 73: 1-25. 1922.—An account of earlier attempts to germinate orchid seed is given. The author employed agar slants on which were sown seed of *Cattleya* and *Laelia*. The nutritive medium was Pfeffer's solution and a modification thereof plus sugars. Fructose proved more favorable for growth of embryos than glucose. A plant extract (yeast, wheat) used with glucose, however, induced satisfactory germination. No gain in germination was obtained beyond 0.08 per cent concentration of the glucose. Introduction of *Bacillus radiculicola* proved definitely favorable. *Azotobacter* sp. retarded growth. Transplantation from tubes to Erlenmeyer flasks, thence to proper soil, was practiced. This method is believed to be commercially valuable. Regarding fungus relations the author suggests that "germination is induced not by any action of the fungus within the embryo but by products produced externally on digestion or secreted by the fungus." A final statement is made, however, that at this time the "validity of the fungus hypothesis cannot be proved or disproved."—*B. W. Wells.*

1479. WANSER, H. M. Photoperiodism of wheat; a determining factor in acclimatization. *Science* 56: 313-315. 1922.—From a study of the data for the behavior of winter and spring wheats as regards jointing and heading, it is concluded that there exists a critical stimulus for jointing and that it is a critical photoperiod with a maximum limit. Winter wheat also requires a separate and distinct photoperiod for heading but spring wheat can joint and head in the same season.—*C. J. Lyon.*

GROWTH, DEVELOPMENT, REPRODUCTION

1480. CLARK, N. A. The rate of formation and the yield of yeast in wort. *Jour. Phys. Chem.* 26: 42-60. 1922.—The rate of reproduction of "normal," actively budding yeast (*Saccharomyces cerevisiae*, race F) follows the "logarithmic formula," $\log C/C_0 = 0.160 t$, from the moment of seeding until the concentration is 100 million cells per cc. (regardless of whether seeding was 5 cells or 8 million cells or more per cc.) if the culture is properly shaken and aerated. In this equation C_0 signifies the initial number of yeast cells per cc. and C the number at any time, t . The solution with 100 million cells per cc. contains 1.8 gm. of alcohol per 100 cc. Above this alcohol content the number 0.160 in the equation must be replaced by a quantity that is a function of the percentage of alcohol if the percentage be below 5. The maximum number of cells is about 325 million per cc. although if the wort were heavily inoculated (up to 400 per cc.) the crop might reach 675 million because of the lower alcohol content. If the culture is diluted but contains 10 per cent or more of wort, the rate and the maximum are the same as if pure wort had been used. If less wort is used the rate is the same but the maximum is low because there is too little bios (perhaps the "water-soluble vitamine"). Quantitative measurements of the crop may be used to determine quantitatively the amount of bios; the maximum is reached in about 24 hours. Washed yeast cake rapidly absorbs bios from wort and if enough yeast is used the removal is practically complete and the cells do not bud.—*H. E. Pulling.*

1481. KÖHLER, E. Über rhythmische Erscheinungen bei Wachstum und Gärung der Hefe. [Periodicity in yeast growth and fermentation.] *Biochem. Zeitschr.* 106: 194-206. 1920.—Yeast fermentation and growth during alcoholic fermentation showed periodicity caused by changes in the sugar and alcohol content of the nutrient medium. The rate of growth is determined by the sugar concentration but the growth curve was irregular at high concentrations.—*H. D. Hooker, Jr.*

1482. REED, H. S. A method for obtaining constants for formulas of organic growth. *Proc. Nation. Acad. Sci. [U. S. A.]* 7: 311-316. 3 fig. 1921.—The equation of autocatalysis, $\log \frac{x}{A-x} = K(t-t_1)$ sometimes gives values for x which are somewhat too large in the early life of an organism. The author describes a simple graphic method which may be used to overcome the difficulty. Assuming that the true state of affairs is represented by the equation: $\log \frac{x}{A-x} = K(t-t_1)^c$, we may write: $\log (\log \frac{x}{A-x}) = \log K + c \log (t-t_1)$. This is the equation of a straight line if $\log (\log \frac{x}{A-x})$ be used as ordinate and $\log (t-t_1)$ as abscissa. The intercept of this line on the y -axis will be $\log K$ and the slope of the line, c . Examples of the use of the method are given showing the computed values of x obtained for the growth of shoots on several trees.—*H. S. Reed.*

1483. SCHAFFNER, J. H. Progression of sexual evolution in the plant kingdom. *Ohio Jour. Sci.* 22: 101-113. 1922.—The main factor in the evolution of sexual dimorphism is said to be the shifting of the time when sexual states arise from the neutral state, ranging from a late stage of gametogenesis in the lowest forms backward through ontogenetic history until the sexual state of both sporophyte and gametophyte is established when the egg is fertilized or even before. On this basis plants are classified in 4 main groups: (1) those having no sexual stage; (2) a series with reduction of chromosomes in the zygote or at the end of the sexual generation just before gametogenesis; (3) a homosporous series with antithetic alternation of generations; and (4) a similar heterosporous series with the gametophytes unisexual and the sporophytes bisporangiate or monosporangiate. Since the sexual state is usually determined in somatic cells when neither segregation nor association of chromosomes is taking place, it is concluded that sex cannot be associated primarily with special chromosomes and that fundamental sexual phenomena are caused by properties entirely apart from Mendelian units.—*H. D. Hooker, Jr.*

1484. SPEK, J. Beiträge zur Kolloidchemie der Zellteilung. [The colloid chemistry of cell division.] *Kolloidchem. Beih.* 12: 1-91. 1920.—Many observations during the author's 3-year study support O. Bütschli's hypothesis that changes in surface tension induce cell division, but questions concerning the physical chemistry of the process were untouched by Bütschli. Of these the chief are: Is a definite water content necessary for cell divisions? Does increase in water content lead to division? Recent researches of others establish an increased permeability of the cells just before division and this the author thinks must be due to either increased swelling of membrane and plasma colloids or to a decrease in the precipitating power of the outer medium. Since the latter does not take place the former must occur, either by increased hydration or plasma alteration in the direction: gel to sol; or both. If by any means the permeability is increased, water will be absorbed unless the plasma is saturated, so that increase in water content might not induce cell division but only accompany it. If increase in water content is causative, treating the cell with reagents that increase imbibition (previous researches indicated that the ions affect it in the following order: $\text{SCN} > \text{I} > \text{BR} > \text{NO}_3 > \text{ClO}_3 > \text{Cl} > \text{acetate} > \text{SO}_4$; $\text{Li} > \text{K} > \text{Na} > \text{alkaline earths}$; fatty acids and narcotics also increase imbibition) should induce cell division. This is known to be true, especially from work on artificial parthenogenesis. The author also tested this, using *Paramoecium* in salt-solution-hay-infusion cultures. In all experiments decidedly more abundant cell division occurred in the medium than in the controls, frequently 10 times as much. Salts that do not penetrate the

protoplasm withdraw water by osmosis and decrease the rate of growth and the rate of division, whereas the effective salts increase the volume of the cell. Concerning the action of the salts the author suggests that before division the cell becomes more liquid at the expense of those protoplasmic structures that maintain the form of the cell. This increase in fluidity permits hydrodynamic effects and the cell becomes more nearly spherical and stains less vividly. This is also characteristic of those pathological (embryonal) conditions that are characterized by rapid cell division. There are now 2 possibilities: (1) gas exchange is easier when the plasma is more fluid and respiration is more rapid. This should be experimentally investigated. (2) There is an acceleration of those processes in which water directly plays a part. At the beginning of cell division there is formation of nucleoproteins and this is supposed to be at the expense of bodies that contain lecithin and phosphoric acid. But since lecithin is thereby hydrolyzed, the importance of water in the first steps of the chemical degradation of cell materials is indicated. At the outset the process proceeds with the normal amount of water and oxygen, but during nuclein formation probably a base (cholin) is liberated which increases imbibition by the colloids, increases the amount of water that is held, facilitates gas exchange, and so increases the formation of nucleoproteins. The author discusses the mechanism of parthenogenesis and reviews the literature of cell division, the experimental evidence of which, he believes, supports his conceptions.—*H. E. Pulling.*

MOVEMENTS OF GROWTH AND TURGOR CHANGES

1485. BREMEKAMP, C. E. B. Über den Einfluss des Lichtes auf die geotropische Reaktion. [The influence of light on the geotropic reaction.] *Recueil Trav. Bot. Néerland.* 18: 373-438. 3 pl., 9 fig. 1921.—In these experiments there were used coleoptiles of a pure-line *Avena*. As an average geotropic reaction was desired the plants were kept in a horizontal position for 5, 15, 20, 30, or 45 minutes (usually 20 minutes), but when the centrifugal apparatus was used the time of induction was considerably shortened. The strongest light source was a Philips $\frac{1}{2}$ Watt lamp op + 300 H. K., the heat rays of which were absorbed by a cooling apparatus. The light was examined at intervals by a Weber photometer.—When illuminated seedlings are in a horizontal position, the normal geotropic curvature is followed by an antitrope curvature. If, before illumination, seedlings are placed directly in a horizontal position, the antitropous curvature is at first noticed at the apex, extending later toward the base. Plants remaining erect for a time after illumination do not show antitropous curvature at the top; but in regions progressively further from the apex, more time elapses between illumination and orientation in a horizontal position.—The amount of photogenic antigeotropic curvature depends upon time and intensity of illumination.—A one-sided illumination when strong enough is as important as a several-sided illumination in causing an antigeotropic curvature in plants which remain for some time in the horizontal position, though too much time should not elapse between the illumination interval and the horizontal arrangement.—*J. C. Th. Uphof.*

1486. MERL, EDMUND M. Biologische Studien über die Utriculariablase. [Biological studies of the Utricularia bladder.] *Flora* 115: 59-74. 3 fig. 1922.—Repetitions and original experiments led to the following conclusions: the engulfing of small animals is not due to their activity but to the action of the bladder; contracted bladders are in an irritable condition and a touch upon the bristles or the lip near the bristles causes the lip to contract, forming an opening, and the walls of the bladder to expand so that the suction created draws in whatever may be in the vicinity of the opening; after a resting period the bladder is again irritable; when bladders are removed from water partial drying causes a difference in tension which brings about the reaction; puncture causes permanent expansion. The reaction is bound up with the turgescence of the plant but is difficult to explain. No effect is produced by ammonia, glycerine, alcohol, mercuric chloride, ether, chloroform, an electric current, or lowered atmospheric pressure. Irritability could not be eliminated by cold, heat, or narcotics until there was serious injury to the bladder. A stimulus does not appear to change the size of the intercellular air spaces, as in *Mimosa*, although this is difficult to determine under the high power necessary for observation. The position, shape, and action of the bristles suggest the stimula-

tion theory. Another explanation suggested is that the elastic lip and side walls are in equilibrium; the slightest motion disturbs this and the lip and walls spring back; the inner hairs absorb water and restore equilibrium. The 2 difficulties confronting this theory are: (1) the bladders act the same whether filled with air or water; (2) the extreme slowness of water movement in plant plants. Methylene blue quickly stains the inner hairs, but there is no movement in the vessels.—*L. M. Snow.*

1487. SIERP, HERMANN. Über den Einfluss geringer Lichtmengen auf die Zuwachsbe-
wegungen der Koleoptile von *Avena sativa*. [The influence of small quantities of light on the
growth movement of the coleoptile of *Avena sativa*.] Ber. Deutsch. Bot. Ges. 37: 123-128.
1919.—The author's measurements of the change in growth rate of oat coleoptiles after expo-
sure to relatively weak light stimulation were prompted by Vogt's statement (Zeitschr.
Bot. 7: 1915) that illumination of 2880 meter-candle-seconds (M.C.S.) (16 meter-candles [M.C.]
for 3 minutes) or less produced no distinct change in the growth rate of the coleoptiles, and by
Blaauw's reference of [Zeitschr. Bot. 6: and 7:] the phototropic curvatures (which he secured
with illumination intensities as low as 10-20 M.C.S.) to the influence of light upon the growth
rate of the illuminated side of the coleoptile. Sierp found changes in the growth rate follow-
ing such weak stimulation as 10 M.C.S. (10 M.C. for 1 second). His tables and curves show
the changes in growth rate for a period of 4 hours after exposure to illumination of 10, 100,
and 2000 M. C. S.—*R. M. Holman.*

1488. WEEVERS, TH. Concerning the influence of light and gravitation on *Pellia epiphylla*
(Corda). Proc. Roy. Acad. Sci. Amsterdam [translated from Verslag K. Akad. Wetenschappen
Amsterdam] 24: 2-11. 1921.—Experiments are presented on the phototropic, photogrowth,
and geotropic reactions of the growing sporogonium stalks of *Pellia*. The entire stalk is per-
ceptive of the stimulus and any stimulated part may respond. In phototropic experiments,
stalks 15-25 mm. in length were used. Exposed unilaterally to sunlight, distinct curvature
appears in 5 minutes. The minimum stimulus effecting a response was light energy equiva-
lent to 400 meter-candle-seconds (M. C. S.); reaction time was 150 minutes. The shortest reac-
tion time was effected by 15,000,000 M. C. S. This is contrasted with the shortest reaction time
for *Avena*, which is about 100 M. C. S. No pronounced negative reaction was observed.—
The blue rays are shown to be the effective rays.—Using light of 75 M. C. with an energy value
of 22,500-45,000 M. C. S., a distinct photogrowth reaction was produced on the sporogonium
stalks of plants that had been kept in the dark. The mean retardation in growth of 6 observa-
tions was 35 per cent.—Stems are negatively geotropic. The minimum exposure period result-
ing in a reaction was 10 minutes and the reaction time was 150 minutes. The author suggests
that turgor changes have nothing to do with curvature of the stalk and that an explanation
must take into consideration the colloidal chemistry of protoplasm and cell wall.—*L. Knudson.*

GERMINATION, RENEWAL OF ACTIVITY

1489. BAINES, A. E. Germination in its electrical aspect. 185 p., 130 fig. George
Rutledge & Sons: London; E. P. Dutton & Co.: New York, 1921.—The author contends that
plants possess electrical systems and that such organs as fruits, seeds, and stems are electrical
cells incapable of being polarized. For example, the edible portion of the apple, charged
positively by the air which enters at the open calyx end, continuously induces a negative
charge in the core, from which it is separated by a non-conductive tissue. Such processes
as cell division, growth, seed germination, and life itself, inexplicable on the basis of chemical
reactions alone, are dependent on stimuli which are electrical in nature. "The fundamental
principle governing the nature of a seed is this: the seed substance must receive a continuous
charge of electricity; this charge must be induced or the seed would rot, and no such charge
can be imparted until the seed becomes in effect a Leyden jar." Plants grown in electrified
soil exceed controls and in electrified soil less moisture is required to produce a given amount
of growth. An attempt is made to explain hearing, sleep, and allied phenomena, even cancer,
on the basis of electrical stimuli, though few practical data are presented. [See also Bot. Absts.
10, Entry 1976; 11, Entry 816].—*S. G. Lehman.*

1490. FRYER, J. R. Influence of light and fluctuating temperature on the germination of *Poa compressa*. Sci. Agric. 2: 225-230. 1922.—Sunlight was believed to be somewhat beneficial in germinating *Poa compressa*. Daily fluctuations in temperature between 16 and 35°C. were most suitable and better than a steady temperature.—B. T. Dickson.

1491. McHARGUE, J. S. Some points of interest concerning the cocklebur and its seeds. Ecology 2: 110-119. 1 fig. 1921.—The writer lists the native species of *Xanthium* as *X. canadense*, *X. commune*, *X. speciosum*, and *X. echinatum*; while those native of the old world are, *X. spinosum* and *X. strumarium*. Possibilities of the use of the seed for oil and a consideration of the plant as a pest to the agriculturist and wool-growers are given. The morphology of the paired seed in the bur is described and the delayed germination of the smaller one discussed. The older work of Arthur, Masterman, and Crocker which furnished the theory that the delay in germination of the smaller seed until the 2nd spring is due to differences in the enzyme content of the embryo or to differences in the character of the seed-coats is reviewed. With selected-seed of *X. commune* the writer found equal amounts of oxidases and peroxidases, indicating equal viabilities in large and small seed. Germination tests of seed removed from the burs showed that 100 per cent of the larger seed and 86 per cent of the smaller germinated in a given time with a tardiness of 24 hours as a mean for the smaller. There is no marked dormancy of such seed and no inherent property for delayed germination in embryos or seed-coats. Another series of tests showed that the conditions in the bur were the cause of the delay in *X. commune*. The septum of the bur which protects the smaller seed is thicker and shorter than that of the larger seed and this prevents the absorption of oxygen or moisture as readily as in the larger. By the 2nd spring this septum has disintegrated enough to allow germination of the smaller seed. Occasionally simultaneous germinations do occur. Differences in vigor of the 2 seedlings are due to the larger amount of food in the large seed; other tests showed the presence of a glucoside in larger amounts in the large seed. Sugars are formed from fats or cellulose as these seed contain no starch. The presence of oxidases, peroxidases, catalase, proteolytic and lipoclastic enzymes was demonstrated. Histological examinations showed that the cells of large and small seed are identical.—H. H. M. Bowman.

1492. WEBB, ROBERT W. Studies in the physiology of the fungi. XV. Germination of the spores of certain fungi in relation to hydrogen-ion concentration. Ann. Missouri Bot. Gard. 8: 283-341. Fig. 1-39. 1921.—In continuation of work previously reported [see Bot. Absts. 4, Entry 1575] Webb has broadened his experiments on the effects of active H- and OH-ions upon germination by the use of solutions other than mannite, such as Czapek's solution, peptone, beet decoction, water, and mannite + beet decoction. The spores of the following fungi were utilized: acid forms, *Botrytis cinerea*, *Aspergillus niger*, *Penicillium cyclopium*, *P. italicum*, *Puccinia graminis*, and *Lenzites saepiaria*; acid and alkaline form, *Fusarium* sp.; alkaline form, *Colletotrichum Gossypii*. Experiments show that under favorable nutritive conditions the active H-ions are favorable to germination while the OH-ions are relatively detrimental. The optimum active acidity for a majority of the fungi seems to range between pH 4.0 and 3.0. The limits on the acid side are comparatively narrow, inhibition being reached near pH 2.5-1.5. The limits on the alkaline side are very diverse, varying with the organism and medium. The various nutritive solutions used gave different ranges, and percentages, of germination. From visual observations the mycelial growth is inhibited by virtually the same H- and OH- ion concentrations as those which have inhibitive action on germination. In equal concentrations of the 2, the OH- ions are relatively more toxic to spores than the H-ions. The composition of the medium seems to influence the activity of the OH-ions in this respect more than the H-ions may be antagonized. The range of shifting of reaction depends on the organism and composition and original reaction of the medium. Under conditions of active alkalinity the range of germination in beet decoction is noticeably expanded. Germination here may be stimulated by some special substance or condition (possibly buffer effect?), which may be wanting in synthetic media.—Increasing the incubation period does not change the relation of germination to H-ion concentration. "The curves of germination for any organism are practically identical, whether incubated at a temperature representing a pro-

visional optimum, or at 4-5°C. above or below such an optimum. Germination often occurs feebly in cultures possessing a H-ion concentration closely approaching that of inhibition" and differences manifest within favorable ranges tend "to occur over the widest range at the optimum temperature." The data developed in this paper are of fundamental importance in the future study of acid or alkaline fungicides or spray mixtures which may be applied to control the germination of fungous spores.—S. M. Zeller.

1493. YOUNGMAN, W. The influence of atmospheric conditions upon the germination of Indian barley. Mem. Dept. Agric. India Bot. Ser. 11: 145-151. 1921.—Experiments on the influence of humidity on the germination of Indian barley are described. A vapor pressure of 0.87 inches (0.0213 gm. water vapor per l. of air) may be taken as the safest maximum to which Indian barley, intended for export for malting purposes, may be exposed. Exposure for 14 weeks to this degree of humidity has no deleterious effect. Exposure to greater amounts of humidity than this is serious. A vapor pressure of 0.89 inches (0.0216 gm. water vapor per l.) after 14 weeks or less reduces the germination by some 25 per cent, and higher humidity totally destroys germinating power in 14 weeks or less.—A. Howard.

TEMPERATURE RELATIONS

1494. EVANS, CLYTEE R. Effect of temperature on germination of *Amaranthus retroflexus*. Bot. Gaz. 73: 213-225. Fig. 1-4. 1922.—A summary of the literature dealing with the temperature factor is given. The author finds that the behavior of *Amaranthus* seed parallels the data of Leitch (pea seedlings), Lebenbaur (corn seedlings), and Ball (sore shin fungus) with regard to coefficients relating rate of germination to temperature. For methods of seed treatment (abrasion, acid) the general trend of the coefficients was the same. The restricting effect of the coats is shown particularly in the case of after-ripened seed at low (8-11.6°C.) and at high (42-46.1°C.) temperatures. These effects can be lessened by treating the coats with sulphuric acid or abrading them with sand.—B. W. Wells.

1495. SIGALAS, R., et H. MARNEFFE. A propos de la résistance de quelques graines à de hautes températures. [The resistance of certain grains to high temperatures.] Compt. Rend. Soc. Biol. 87: 193-195. 1922.—Experiments confirm Gain's discovery that the seed of *Helianthus annuus* L. may be exposed to heat up to about 150°C. without losing the power to germinate.—S. Morgulis.

1496. STEVENS, NEIL E. Environmental temperatures of fungi in nature. Amer. Jour. Bot. 9: 385-390. 1 fig. 1922.—Plant parts when exposed to the sun often show a temperature which is markedly above that of the air and which may fluctuate more rapidly and extremely than does the air temperature in the shade. The temperature environment of the fungi which grow on these plant parts must therefore differ widely from that which is usually supplied them when growing in pure culture in heated laboratories.—E. W. Sinnott.

RADIANT ENERGY RELATIONS

1497. HARVEY, R. B. Growth of plants in artificial light from seed to seed. Science 56: 366-367. 1922.—By the use of continuous artificial light, crops of wheat, oats, barley, rye, potatoes, buckwheat, lettuce, beans, peas, radishes, etc., were grown and produced viable seed in seasons much shorter than by daylight. No such fixed period of illumination, as found essential by Garner and Allard, seemed necessary except for cabbage. Plant breeders can use this method to produce more generations.—C. J. Lyon.

TOXIC AGENTS

1498. CLOWES, G. H. A., and H. W. SMITH. Carbon dioxide as an inhibitor of cell growth. Jour. Biol. Chem. 50: Proc. IV. 1922.—Carbon dioxide has an inhibitory effect in cell growth, bearing no relation to H-ion concentration.—G. B. Rigg.

1499. COOK, F. C. Changes in the composition of the Irish potato tuber during growth with particular reference to the influence of copper sprays. *Jour. Biol. Chem.* 50: Proc. XIII. 1922. —Copper sprays have a beneficial effect on the growth and development of potato tubers. This was true in northern Maine in 1921 when no *Phytophthora infestans* was present.—G. B. Rigg.

1500. DOERR, R. Zur Oligodynamie des Silbers. [Oligodynamics of silver.] *Biochem. Zeitschr.* 106: 110–133. 1920.—Water long in contact with metallic silver becomes bactericidal (oligodynamic). The disinfectant property was quantitatively decreased by dilution with distilled water and quantitatively increased upon concentration by distillation. Sodium chloride was antagonistic, weakening and delaying the bactericidal effect. Horse serum destroyed it. Some bacteria were more susceptible than others to metallic silver. Solutions of silver salts had all the properties of the bactericidal water, which was thought to owe its oligodynamic property to silver oxide in solution.—H. D. Hooker, Jr.

1502. GUÉRIN, P. L'action du chlore et de certaines vapeurs sur les plantes supérieures. [The action of chlorine and certain vapors upon the higher plants.] *Ann. Sci. Agron. Française et Étrangère* 38: 10–19. 1921.—The literature is briefly reviewed and the results of a series of experiments on many genera and species of higher plants with chlorine, methyl mono-chlor chloroformate, bromacetone, ethyl di-chlor sulphide (mustard gas), chloroform, ether, ethyl chloride, several alcohols, phenols, and aldehydes are reported. Chlorine gas was most severe in its action, causing the plants to lose their leaves. In other cases the effects varied from a slight bleaching to a blackening of the leaves. The effect of the treatments is a plasmolysis, which was proved by microscopic examination of affected tissue and by the reddening of sodium picrate papers suspended in vessels above treated plants. It is claimed that in the plasmolytic action hydrocyanic acid liberated by the action of emulsin on a glucoside acts on the paper. Certain odors emanated by some plants during treatment are noted as further evidence of plasmolysis.—A. B. Beaumont.

1503. MÜLLER, ALFR. Die Resistenz der Milzbrandsporen gegen Chlor, Pickelflüssigkeit, Formaldehyd und Sublimat. [The resistance of anthrax spores to chlorine, pus, formaldehyde, and sublimate.] *Dissertation.* 12 p. München, 1920.

1504. NEMEC, A., und F. STRANAK. Beitrag zur Kenntnis des toxischen Einflusses der Terpene auf die höheren Pflanzen. [The toxicity of terpenes to the higher plants.] *Biochem. Zeitschr.* 104: 200–213. Pl. 1–7. 1920.—Characteristic alterations in histological structure arose from subjecting plants to terpene vapors. The xylem tracheae and epidermis became brown in sprouted beans, corn, yellow lupines, and peas, and black in etiolated specimens of these plants. The discoloration is attributed to oxidation of tannins to so-called humins by peroxidases, the terpenes playing the role of peroxides.—H. D. Hooker, Jr.

1505. WINDISCH, W., W. HENNEBERG, und W. DIETRICH. Über die Einwirkung oberflächenaktiver Nonylsäure und einiger oberflächenaktiver höherer Homologe der Alkoholreihe (Amylalkohol und Octylalkohol) auf die Hefezelle und die Gärung. [The influence of nonylic acid, amyl alcohol, and octyl alcohol on yeast and fermentation.] *Biochem. Zeitschr.* 107: 172–190. 1920.—Nonylic acid in concentrations ranging from 0.005 to 0.02 per cent and octyl alcohol in concentrations from 0.017 to 0.04 per cent retarded and finally stopped fermentation, inducing pathologic conditions and eventually death of the yeast cells. Alteration of cell shape and fat formation occurred at the same time. These phenomena are attributed to "surface activity" and not to chemical properties. This influence is thought to have practical significance as the same or similar "surface active" compounds arise during fermentation.—H. D. Hooker, Jr.

ELECTRICITY AND MECHANICAL FORCES

1506. STERN, KURT. Über polare elektronastische Erscheinungen, 3 Mitteilung. [On polar electronastic phenomena. Third communication.] Ber. Deutsch. Bot. Ges. 40: 43-51. Fig. 1-2. 1922.—The question which the author seeks to answer is: How do the polar reactions of *Mimosa pulvini* behave with different stimulus intensities, (a) of direct current, (b) of condenser discharge, and (c) of induction shock? Attention is called to 3 important sources of error which are related (1) to the effect of different current intensities, (2) to the formation of parallel currents or branching currents, and (3) to the stimulus-conducting processes. Although the applied potential in volts is often used (by Bose, the present author, and many others) as an approximate measure of an electrical stimulation, the electrical potential as such does not act as a stimulus. This is shown by the fact that when a *Mimosa* plant standing upon a paraffin plate is brought into contact with the pole of an electrical conductor charged to 240 volts, no visible reaction ensues, although the plant is thus charged to this high potential. However, when the pot is grounded an intense reaction follows, the result not of the mere charge but of the passage of a current from the 240-volt pole to the earth. It is the strength of this current and not the potential applied which, other things being equal, determines the stimulus. Since the resistance offered by the plant to the passage of the current influences the strength of the current, the voltage applied can be used as a measure of the stimulus intensity only when the current passes through the same portions of the plant or through portions of the same or different plants offering equal resistance. Experimentally, the resistance is not proportional to the length of the region of the plant through which the current passes, due probably to differences in diameter of the water-conducting elements in different parts of the plant (e.g., stem and petiole). Leaflets of the same leaf differ greatly in resistance, and old leaves offer much greater resistance than corresponding portions of younger leaves, presumably on account of the presence of more air in the vessels of the older leaves. Strength of current and also the dimensions of the cross section of the organ stimulated must be taken into account in determining the intensity of the stimulus. Errors may arise as the result of the sudden movement of the whole shoot (a movement which often interrupts the current by destroying the contact of one of the electrodes) when the circuit is closed.—*R. M. Holman.*

MISCELLANEOUS

1507. HARRISON, ARTHUR P. A simple gas generator for laboratory use. Science 56: 287-288. 1922.—This paper explains the construction and operation of a generator suitable for gases used in the laboratory in comparatively small quantities. It can be made of materials found in all laboratory equipment and but 1 generator is needed for the several gases.—A wide mouth bottle contains the acid, the stopper of which has a small stopcock opening and a larger hole for the insertion of a large test tube. Into this tube is set (through a rubber stopper) a smaller test tube containing the solid reagents. Contact between reagents is effected by small holes in the bottoms of the tubes, and the gas pressure controls the entrance of the acid.—*C. J. Lyon.*

(See also in this issue Entries 1645, 1652, 1759, 1777, 1782, 1801, 1811, 1836, 1873, 1887, 2039, 2080, 2132, 2133, 2160, 2162)

1532. ANONYMOUS. A classification and detailed description of some of the wheats of Australia. Commonwealth of Australia Inst. Sci. and Indust. Bull. 18. 48 p., 5 pl. (1 colored). 1920.—Classification is based upon 8 botanical and 4 agricultural characters, each of which is described in some detail. There are described 43 varieties of *Triticum sativum*, included in 22 "types," and 3 varieties of 3 types of *T. durum*. The history of each variety is indicated.—*L. R. Waldron*.

1533. ANONYMOUS. Det kgl. danske Landhusholdningsselskabs Generalforsamling. [The Royal Danish Agricultural Society's annual general meeting.] Tidsskr. Landokonomi 1922: 125-142. 1922.—This article gives the society's recommendations for a better system of regulating the importation of grain and cattle feed into Denmark.—*Albert A. Hansen*.

1534. ANONYMOUS. Die Feststellung des Düngerbedürfnisses der Böden durch einfache Düngungsversuche. [Determining the fertilizer requirement of soils by simple fertilizer experiments.] Mitteil. Deutsch. Landw. Ges. 37: Flugblatt 62. 1922.—Popular.—*A. J. Pieters*.

1535. ANONYMOUS. Tobacco growing in Ireland. The experiments in 1921. Jour. Dept. Agric. Ireland 22: 26-30. 1922.—Various difficulties in growing and marketing are detailed.—*Donald Folsom*.

1536. BAKER, O. E., C. F. BROOKS, J. R. COVERT, and R. G. HAINSWORTH. Seedtime and harvest. A graphic study of seasonal work on farm crops. U. S. Dept. Agric. Dept. Circ. 183. 53 p. 1922.—This is a presentation of maps showing dates when planting, harvesting, and other operations are performed in the culture of staple crops in different parts of the U. S. A.—*L. R. Hesler*.

1537. BARTLETT, H. Western wheat growing competition. An analysis of the scale of points. Agric. Gaz. New South Wales 33: 714-718. 1922.—The following points are discussed: trueness to type, freedom from disease, evenness, cleanliness, condition and appearance, and apparent yield.—*L. R. Waldron*.

1538. BECKETT, EDWIN. *Potatoes, with a chapter on the artichoke.* 31 p. Country Life: London; Charles Scribner's Sons: New York, 1922.—A brief consideration of the subject in 10 chapters, covering history and general notes; the most suitable soils and their preparation; time and methods of planting, harvesting, and storing; raising in hot beds and cold frames; exhibition work; seed selection for new varieties; insect and fungous diseases; and a classification of a few varieties as to season, outdoor, bed and frame, and exhibition purposes. A final chapter is devoted to the artichoke, covering briefly its history, planting, harvesting, varieties, and preparation for the table.—*P. L. Ricker.*

1539. BEVERIDGE, WM. *Weather and harvest cycles.* *Economic Jour.* 31: 429-452. 1921.—Detailed harmonic analysis of data on the price of wheat in Western Europe during the 300 year period 1500-1869 discloses about 20 distinct cyclic periods varying in length from 2.2 to 68 years. When 11 of the most pronounced of these cycles are combined into a single "synthetic" curve and this curve projected through the years since 1850 it is found that this hypothetical projection synchronizes very closely with a similar curve for rainfall during that period. Especial significance is attached to the fact that the depressions in the price curve are followed by periods of lack of rain, lack of rain being generally beneficial to wheat in the area under discussion. The investigator believes that periodicity in weather exists, although he does not consider prognostication possible without more elaborate investigation.—*L. W. Kephart.*

1540. BOLLEY, H. L. *Potatoes, varieties for North Dakota.* [In: *Potato hand book.*] North Dakota Agric. Exp. Sta. Ext. Div. Circ. 50. 2-7, 3 fig. 1922.—Points in selecting varieties and the best varieties for the state are considered, followed by notes on the merits of other varieties.—*P. L. Ricker.*

1541. BREAKWELL, E., and G. G. ST. CLAIR POTTS. *Sudan grass.* New South Wales Dept. Agric. Farmers' Bull. 126. 17 p., 4 fig. 1919.—Sudan grass was introduced into New South Wales in 1913. It is adapted to all localities below 3000 feet elevation but thrives best along the coast and under irrigation. At Nyngan it has matured seed and attained a height of 5 feet on less than 4 inches of rain. Sudan grass has generally greatly outclassed millets in yield. It responds very readily to fertilizers. Perennial strains of Sudan grass have been reported from 2 localities. Cultural notes are given.—*L. R. Waldron.*

1542. BURGESS, J. L. *Limestone in relation to agriculture.* Part 1. *Limestone and soil fertility.* Part 2. *Future of the agricultural lime industry.* Bull. North Carolina Dept. Agric. 1922: 1-24. Sept. 1922.—This is a revision of Bull. 9 (whole number 265) 1919, and contains no new material. It is published also in *Rock Products* 22: Nov. 1919.—*F. A. Wolf.*

1543. BURSE, W. *Möglichkeiten und Ziele für den deutschen Tabakbau.* [Possibilities and aims for German tobacco culture.] *Mitteil. Deutsch. Landw. Ges.* 37: 602-605, 616-618. 1922.—The author points out that the most important matter is improvement in the quality of German-grown tobacco. Some of the problems of selection, breeding, soils, and fertilizers are discussed.—*A. J. Pieters.*

1544. BUSS. *Ein Beitrag zur Futterpflanzenzüchtung.* [A contribution to the breeding of forage plants.] *Mitteil. Deutsch. Landw. Ges.* 37: 443-445. 1922.—A general statement of methods and of difficulties is presented. Isolation of selections in the field has proved more satisfactory than caging. Vegetative reproduction where possible is an effective method of preliminary increase.—*A. J. Pieters.*

1545. CALVINO, M. *El cultivo herbáceas de una planta arbórea para producir abono verde.* [Cultivation of an arboreal plant to produce green manure.] *Mem. Soc. Cubana Hist. Nat.* "Felipe Poey" 4: 32-43. Pl. 1. 1922.—The author discusses the value of *Cassia siamese*, Lamk. as a source of green manure and recommends its use for reforestation. He also calls attention to *Albizia lebbek*, Benth. and *Prosopis juliflora* (Sw., E. DC.) for similar purposes.—*J. A. Faris.*

1546. CHAMBLISS, C. E. Wild rice. U. S. Dept. Agric. Dept. Circ. 229. 16 p., 2 fig. 1922.—Wild rice (*Zizania aquatica* L. and *Z. palustris* L.), which is distantly related to cultivated rice, is the principal food of wild ducks and other waterfowl and is used to a limited extent by man. A discussion of the growing of wild rice is given.—*L. R. Hesler*.

1547. CHEEL, E. The weeds of civilization. Australian Nat. 5: 25-28. 1922.—The author tells how the weeds were introduced and gives the names of some of the more common ones. *Leucaena glauca* Benth. causes horses to lose the hair of the mane and tail, and causes pigs to lose all hair.—*T. C. Frye*.

1548. CHOMLEY, F. G., and F. A. CHAFFEY. Producing lucerne hay under irrigation. Methods and experiences at Yanco experiment farm. New South Wales Dept. Agric. Farmers' Bull. 143. 22 p., 19 fig. 1921. [See Bot. Absts. 11, Entry 19.]

1549. CHRISTENSEN, ANTON. Intryk fra Islands Landbrug. [The agriculture of Iceland.] Tidsskr. Landokonomi 1922: 261-293. 1922.—The island appears to have little future as an agricultural country since grass crops are not produced to any extent because of the rigorous climate. Iceland is better adapted to raising cattle and sheep, as the climate is well suited to the production of hay. Potatoes, cabbage, and turnips make good growth.—*Albert A. Hansen*.

1550. CONNER, A. B., and R. E. KARPER. Shelling percentage in grain sorghum. Texas Agric. Exp. Sta. Bull. 294. 2 p. 1922.—Sixty million bushels of grain sorghum are produced annually in Texas. The data extend over a period of 6 years. The grain content of the heads varies from 69.53 to 75.23 per cent, or from 1390 to 1504 pounds to the ton of heads. Individual strains show considerable variation.—*L. Pace*.

1551. COPLAND, D. B. Wheat production in New Zealand. Chapter on Improvement in wheat by selection in New Zealand by F. W. HILGENDORF. Introduction by JAMES HIGHT. xx + 311 p. Whitcombe & Tombe, Ltd.: Auckland and London, 1921 (?).—This is mainly an economic treatise published "in the hope that it may help to form a sound public opinion on an industry which has for the last few years been thrust unpleasantly into public notice through the shortage of home-grown supplies of wheat, difficulties of importation, high prices, and the inconveniences of government regulation." Consumption, production, quality improvement and prices of wheat, general conditions, history, periods, cost of production, and other related topics are considered. In the chapter on improvement the methods of developing and introducing pure strains of wheat are outlined. "College Hunter's," a pure line of Hunter's (one of the important wheats of New Zealand) has been introduced. Preliminary trials indicate that it yields 4 bushels per acre more than the commercial seed. Promising strains of this and other varieties are still under trial.—*C. E. Leighty*.

1552. COUEY, WORTH G. The potato seed plot. [In: Potato hand book.] North Dakota Agric. Exp. Sta. Ext. Div. Circ. 50. 19-21. 1922.—Preparation of the seed plot, planting, and inspection for diseases are discussed.—*P. L. Ricker*.

1553. DAVIDSON, W. D. Profitable potato growing. Jour. Dept. Agric. Ireland 22: 140-149. 2 fig. 1922.—Recommendations are detailed for improving the current Irish methods.—*Donald Folsom*.

1554. DIETRICH, F. O. Zur Phosphorsäurefrage. [The phosphoric acid question.] Mitteil. Deutsch. Landw. Ges. 37: 600-602. 1922.—In this general statement regarding the necessity of phosphates, the author refers to some of the important papers but adds no new data.—*A. J. Pieters*.

1555. DOBRESCU, I. M. Le climat et la blé roumain. (Das Klima und der rumanische Weizen.) [Climate and Roumanian wheat.] Bull. Soc. Științe Cluj 1: 171-176. 1921.—The

Roumanian soils as well as the climate are well suited to the culture of wheat. The author inquires in how far the climate influences wheat yields. He establishes the fact that the quantity of the crop depends on the intensity of assimilation before blooming time, which means for Wallachia before the end of May and for Moldavia by the middle of June. This assimilation is again dependent on the water content of the soil and consequently on the rainfall. The quality of the crop on the other hand is controlled by the light and temperature relations during the formation of the kernels, thus favored by dry, warm weather from blooming to maturity. According to the writer, these favorable conditions obtain all over Roumania, but especially in the neighborhood of Cluj and Botoşani.—*M. Tiesenhausen.*

1556. EASTERBY, H. T. Sugar experiment bureau. Summary of 21 years' work. (Continued.) Part IV. Australian Sugar Jour. 14: 408-412. 1922.—A résumé is given of results of experiments started in 1905 at Mackay to determine the most suitable distances between the plants in the row and the width between the cane rows. Plants only 6 inches apart in the row yielded over 11 tons of cane more per acre than when grown 36 inches apart. Cane from rows planted 4 feet apart gave 20 tons per acre more than when rows were 7 feet apart. Also the yield of sugar per acre was greater for the thicker planting. The variation in distance between the rows had a much more definite bearing upon the crop results than the variation of distance between the plants. Soils and climatic conditions have an influence on these results.—*C. Rumbold.*

1557. EASTERBY, H. T. Sugar experiment bureau. Summary of 21 years' work. (Continued.) Part V. Australian Sugar Jour. 14: 479-483. 1922.—There has been a constant introduction and testing of cane varieties at the Mackay Sugar Experiment Station since 1895. They are tested by cropping and chemical analyses. Two of these introduced canes; New Guinea 15 or Badila and N. G. 24 or Goru, are very valuable. The results of the tests in yield of cane and of sugar for these 2 and other canes are given in tables.—*C. Rumbold.*

1558. EASTGATE, J. E. How I grow potatoes in eastern North Dakota. [In: Potato hand book.] North Dakota Agric. Exp. Sta. Ext. Div. Circ. 50. 8-10, 2 fig. 1922.—Time and method of preparing the soil, treatment and planting of seed potatoes, cultivation, harvesting, and loading for the market are discussed.—*P. L. Ricker.*

1559. FINKE, H. L. Potato culture in northwest North Dakota. [In: Potato hand book. North Dakota Agric. Exp. Sta. Ext. Div. Circ. 50. 10-11. 1922.—Details are given of soil preparation, cultivation, and spraying.—*P. L. Ricker.*

1560. FISCHER, HERMANN. Über den Einfluss der Humussäuren auf unsere Kulturpflanzen. [Concerning the effect of humus acids on our cultivated plants.] Mitteil. Deutsch. Landw. Ges. 37: 559. 1922.—The author describes certain effects of humus acids such as the wrinkled, brown spotted leaves of beans and the pale green color of oats, barley, peas, and vetches. Pear leaves become folded and leaves of apple become brown spotted and dry from the margin toward the middle. These effects are said to be due to physiological drying, the plants producing few root hairs and absorbing little of the acid solution.—*A. J. Pieters.*

1561. FRANCK, W. J. Algemeene gezichtspunten betreffende unificatie van de methoden van zaadenderzoek in het belang van den handel, meer speciaal met betrekking tot de zuiverheid van het zaad. [General views on unification of methods in seed testing as to its importance for the trade, and especially with relation to the purity of seed.] Cultura 34: 270-280. 1922.—In recent years much stress has been laid by the seed trade upon uniformity in methods of seed control. In the Netherlands at first the Irish, later the continental system, was used. In the seed trade of the Netherlands the following formula has been much in use: $\text{usefulness} = \frac{\text{purity} \times \text{germinating power}}{100} - 3 \times \text{harmful impurity}$. The writer suggests that in accordance

with his predecessor, F. F. Bruijning, a uniform international technique and system for seed testing should be adopted, and the term grade should be used, since this word is practically the same in all languages.—*J. C. Th. Uphof.*

1562. GASSER, G. W. Report of work at Rampart station. Rept. Alaska Agric. Exp. Sta. 1920: 20-36. Pl. 2-3. 1922.—The report shows that late spring and cool summer nearly resulted in crop failure. Alaska peas were grown both for hay and seed. Oats were also used for hay. *Medicago falcata* is the only hardy alfalfa. *Vicia cracca* and *Trifolium lupinaster* are hardy. Reports are made on spring wheats, oats, and barley, including well known types and many hybrids originated at the station. Hemp and buckwheat ripened 25 per cent of seed while flax ripened only 2 per cent. Turnips, rutabagas, cabbage, and peas ripened seed, but carrots and sugar beets did not. Potatoes in variety were grown, also the following vegetables; pe-tsai lettuce, Swiss chard, carrots, beets, sugar beets, parsnips, spinach, beans, peas, tomatoes, cabbage, cauliflower, turnips, and celery. One head of Copenhagen Market cabbage weighed 27 pounds. Pepper, egg plant, cucumber, and muskmelon were started in the greenhouse and grown in cold frames. Hybrid strawberries from Sitka station produced fruit. Notes on flowering plants are given.—J. P. Anderson.

1563. GERLACH und KÜNTZEL. Über die Aufbewahrung der grünen, wasserreichen Futterpflanzen und der wasserhaltigen Abfallprodukte landwirtschaftlicher Nebengewebe. [Concerning the preservation of green succulent fodder plants and of the succulent waste products of agricultural industry.] Mitteil. Deutsch. Landw. Ges. 37: 630-637. 1922.—The authors describe the various forms of containers in which plant material is preserved. The common unwallled pit is not satisfactory nor is the walled pit as good as the other types, 5 of which are described in some detail, namely, fermentation chambers, German feed tower, peasants silo (Bauernsilo), American feed tower, and electro-feed container. Reference is made to firms dealing in these various types. The authors also discuss under 7 heads the essentials to be observed in the construction of such containers. A bibliography is appended.—A. J. Pieters.

1564. GRAHAM, I. D., and T. D. HAMMATT. Some factors in agricultural cost production. Trans. Kansas Acad. Sci. 30: 225-232. 1919/1921 [1922].—The purpose of this paper is to give in detail the facts which are absolutely necessary in the determination of any reliable statistics concerning 'a] farm crop, including particularly land and buildings, use of machinery, seed, seed bed preparation, harvesting, threshing, hauling to market, insurance, fertilizer, interest on seed and seed bed, crop risk, rent, management, and credit by straw and pasture.—F. C. Gates.

1565. HANSEN, K. Planteavlten 1920. [The harvest, 1920.] Tidsskr. Landokonomi 1921: 421-443. 1921.—An estimate is made of the acreage of the staple crops in Denmark during 1920. A large acreage was seeded to peas for cattle feed and the majority of the root crops were grown for cattle feeding. Potatoes were exported to a limited extent, but the freight rates were too high to permit extensive exportation. During the world war the production of seed crops was highly developed but the production of seed dropped considerably after the war. The 1920 harvest is discussed and statistics presented.—Albert A. Hansen.

1566. HARLAN, H. V., M. N. POPE, and L. C. AICHER. Trebi barley, a superior variety for irrigated land. U. S. Dept. Agric. Dept. Circ. 208. 8 p. 1922.—Trebi barley, a 6-rowed, bearded variety, is a pure line descended from selection of a single plant. Introduced from Asiatic Turkey it is being distributed to American farmers. It is especially adapted to irrigated land in southern Idaho and is recommended for irrigated lands where the summer season is similar to that of southern Idaho. It is not recommended for non-irrigated lands.—L. R. Hesler.

1567. HAUTEN, A. VAN. Einwirkung verschiedener Düngemittel auf Vietsbohnen. [Action of different fertilizers upon the kidney bean.] Jour. Landw. 70: 1-7. 1921.—The effects of the fertilizer combinations, K, N, P_2O_5 , $K + P_2O_5 + N$, $K + N$, $K + P_2O_5$, and $P_2O_5 + N$ upon the growth and yield of the kidney bean are described. Chemical analyses of the ash and the dry substance show that the plants required little N and P_2O_5 , while the need for K was very great. Plots fertilized with K gave the greatest yields, as well as high starch, fat, and ash content.—F. M. Schertz.

1568. HAYWOOD, A. H. The culture of sugar cane in New South Wales. New South Wales Dept. Agric. Farmers' Bull. 139. 36 p., 12 fig. 1921. [See Bot. Absts. 9, Entry 612.]

1569. HOFFMAN, M., und O. NOLTE. Düngungsversuche mit Stickstoffdüngern. [Fertilizer experiments with nitrogenous fertilizers.] Mitteil. Deutsch. Landw. Ges. 37: 540. 1922.—The authors report on a test of nitrogenous fertilizers carried on by cooperating farmers. A tabulated statement of returns from the use of sodium nitrate, ammonium sulphate, ammonium chloride, ammonium sulphate-nitrate (ammoniumsulphat salpeter), and ammonium-potassium nitrate on rye, winter wheat, oats, and potatoes shows that the various fertilizers had practically equal value.—A. J. Pieters.

1570. HOFFMAN, und O. NOLTE. Düngungsversuche mit verschiedenen Kali-Salzen zu Kartoffeln im Jahre 1921. [Fertilizer investigations with various potash salts on potatoes in the year 1921.] Mitteil. Deutsch. Landw. Ges. 37: 497-498. 1922.—Potassium magnesium sulphate, potassium sulphate, and 40 per cent potassium nitrate were tested. In general the yields were greater after using the first.—A. J. Pieters.

1571. HOFFMAN, M., und O. NOLTE. Vergleichende Phosphorsäuredüngungsversuche. [Comparative fertilizer experiments with phosphoric acid.] Mitteil. Deutsch. Landw. Ges. 37: 442-443. 1922.—A comparison of Thomas meal containing 15 per cent citric acid-soluble phosphoric acid and Rhenaniaphosphate containing 11 per cent on rye, barley, oats, and sugar beets showed that the 2 forms were of equal value.—A. J. Pieters.

1572. HOYER, JAMES. Det kgl. danske Landhusholdningsselskabs Kontrol med Korn og Foderstoffer i Kobenhavns Frihavn i Aaret 1921. [The Royal Danish Agricultural Society's control of importing grain and feed into Copenhagen's Free Harbor during the year 1921.] Tidsskr. Landøkonomi 1922: 191-198. 1922.—The author presents numerous tables and discusses the relationship of this society to the importation of grain and feed into Denmark during 1921.—Albert A. Hansen.

1573. JONES, J. M., R. A. BREWER, and R. E. DICKSON. Grain sorghums versus corn for fattening baby bees. Texas Agric. Exp. Sta. Bull. 296. 25 p. 1922.—The test continued 165 days. Details of feeding, preparation of the different foods, care of the stock, climate, and other data are given. The steers fed on grain sorghums, made more economical gains than did those fed on corn.—L. Pace.

1574. KARPEN, R. E. Varieties of cotton in northwest Texas. Texas Agric. Exp. Sta. Bull. 299. 26 p. 1922.—The author reports experiments from 1912 to 1921 at Substation 8, near Lubbock, Texas, about the center of the south Plains region.—Cotton production in the counties wholly or partly in the Plains increased from 9,240 bales in 1909 to 132,489 in 1919. This is due to the selection of varieties better suited for general culture in this locality, to the arrival of cotton growers from the eastern southern states, to freedom from boll weevil, and to the greater amount of land available for cultivation. Cotton has proved one of the most drought-resistant crops for this section. A table shows the precipitation for the period with a minimum of 8.73 inches in 1917 and a maximum of 31.88 in 1915. In 2 other years there was a precipitation of over 31 inches, but all others had less than 20, which, however, was fairly well distributed in spring and summer.—L. Pace.

1575. KIESSLING. Einige Gegenwartsfragen der Pflanzenzüchtung und des Saatbaues. [Some present questions of plant breeding and seed growing.] Mitteil. Deutsch. Landw. Ges. 37: 454-458. 1922.—In this address the author discusses the selection of pure strains out of mixed populations, selection of mutations, and crossing. Most of the improvement work thus far has been by the 1st method though the author believes that crossing holds great possibilities. Special mention was made of the need for breeding, among others, forage crops, clovers, grasses, and vetches. The establishment of gardens for preserving all old varieties

was urged since such varieties may prove useful in breeding. Potato selection was discussed at length and requirements proposed to be met before new varieties might be registered. Suggestions were made regarding the distribution of improved seed.—*A. J. Pieters.*

1576. MATENAERS, F. F. *Neuere Erfahrungen mit der Sonnenblumensilage.* [New experiences with sunflower silage.] *Mitteil. Deutsch. Landw. Ges.* 37: 499-500. 1922.—The author briefly reviews recent work on sunflower silage in the U. S. A., and especially in Montana.—*A. J. Pieters.*

1577. MOODIE, A. W. S. *Field experiments with maize. Grafton experiment farm, 1921-22.* *Agric. Gaz. New South Wales* 33: 709-713. 1922.—Work was done with the Icaming variety. Data upon residual fertilizer effect showed that superphosphate applied Nov. 1919, resulted in a net gain of \$4.25 per acre over no fertilizer and superphosphate applied each year gave a net gain of \$5.40 per acre over no manure, for the crop of 1922.—Time of plowing trials showed a net gain of \$8.65 per acre for the early (winter) plowing over the late (spring) plowing.—Cultivation carried on to tasseling time showed a net gain of \$3.50 per acre in comparison with only 1 cultivation after hilling.—In a comparison of hilling with flat cultivation the average net loss for hilling was \$3.72 per acre.—In a desuckering trial, maize plants were grown individually 12 inches apart in rows 4 feet apart. The maize was planted Oct. 26 and was desuckered Jan. 11. The amount of suckering was heavy. The net loss to the crop from desuckering was \$6.68 per acre; allowance was made for the forage value of the suckers.—*L. R. Waldron.*

1578. MUNTEANU, ANASTASE V. C. *Contribuțiuni la Ameliorarea grâului românesc.* (Teze). [Contribution to the improvement of Roumanian grains. (Thesis)] 94 p., 8 pl. *Cartea Românească*: Cluj, 1922.—The author first discusses the present condition of wheat breeding, then methods used in his work. He started with the commonly esteemed domestic variety "Grâul bălan românesc" of *Triticum vulgare erythrospermum*, of which the botanical and biological characters are given. After 6 years' selection the author secured a type which, besides being highly resistant to rust and lodging, yields 18 per cent more than the parent type. In order to further improve the plants studied, hybridization as well as selection was used. Crossing Line No. 148 with Strubes square head and with Mettes square head, the author secured 6 crosses, all of which exceeded the pure line No. 148 in real value. One of these crosses was grown on 2 hectares with gratifying results. Many tables are included.—*M. Tiesenhausen.*

1579. NEWTON, W. *Forage crops for the Lower Fraser Valley.* *Agric. Jour. [British Columbia]* 7: 36-37. 1922.—In this address varieties of clover are discussed and white Dutch advocated for burned over pasture lands. The use of silage, particularly clover silage, is recommended and the trench silo described. A mixture of orchard grass, tall oats, and meadow fescue is recommended as desirable and timothy declared particularly valuable on the poorly drained delta soils. Intertillage crops and root crops are included in the discussion and mangels designated as the leading root crop for the dairymen of the region under consideration.—*Mary R. Burr.*

1580. NOBLE, E. G. *The work of the Yuma reclamation project experiment farm in 1919 and 1920.* U. S. Dept. Agric. Dept. Circ. 221. 37 p., 10 fig. 1922.—This reports crop experiments on cotton, alfalfa, sorghums, wheat, flax, legumes, orchard fruits, and vegetables.—*L. R. Hesler.*

1581. OBERSTEIN. *Farbmutationen der Kartoffelschalenfarbe.* [Color mutations of potato skin color.] *Mitteil. Deutsch. Landw. Ges.* 37: 666. 1922.—The author describes a tuber mutation in which the color of the tubers was piebald, the boundaries of the white and red color being sharply defined and differing in arrangement in different tubers.—*A. J. Pieters.*

1582. PARK, J. B., C. J. WILLARD, and H. L. BORST. Growing soybeans in corn. Ohio Agric. Exp. Sta. Monthly Bull. 7: 75-78. 1922.—This is a report of 3 years' experience in growing corn and soy beans in combination. It has been found practical to drill the corn and soy beans in the same row and at the same time. The test suggests that the poorer the soil in organic matter and nitrogen the more likely the combination is to out-yield the corn alone, while on rich soil the reverse is true. Suggestions are given regarding the time of planting, also rate and distance of planting. The Peking, Virginia, and Wilson varieties proved especially useful for this practice.—*R. C. Thomas.*

1583. PETERSEN, K. DOLPH. Beretning fra Statsfrokontrollen fra 1 Juli 1920 til 30 June 1921. [Report of state seed control from July 1, 1920, to June 30, 1921.] Tidsskr. Planteavl 28: 129-175. 1922.—Of the 26,922 samples of seed tested, 15,928 were for dealers, 10,271 for growers, and 753 for the state. Samples were received from all parts of Europe and from the U. S. A. The principal kinds were grains, grasses, peas, and beets. The samples were tested for weed seeds, diseases, germination, weight, and water content. Dealers are required to make certain guarantees regarding purity and germination; if the seed does not meet the guarantee an indemnity must be paid, the amount of which is determined by the Board of Seed Control.—*Albert A. Hansen.*

1584. PITT, J. M. Last season's maize yielding contests. The lower north coast. Agric. Gaz. New South Wales 33: 695-702. 1922.—Yields are given for various varieties at different localities.—*L. R. Waldron.*

1585. RADER, F. E. Report of work at Matanuska station. Rept. Alaska Agric. Exp. Sta. 1920: 48-58. Pl. 6-8. 1922.—Rye wintered perfectly. Of spring grains, several varieties each of barley, wheat, and oats were grown. Some varieties of each ripened and produced well, but others were only partly ripe when frosted Sept. 23. Sunflowers for silage did not do well. Smooth brome grass, Kentucky blue grass, timothy, and meadow fescue wintered well; but orchard grass, reedtop, Italian rye grass, English rye grass, and crested dogs-tail mostly winter-killed. About 40 per cent of Grimm alfalfa survived the winter, but common and Turkestan alfalfas were killed. A few red clover plants and not over 50 per cent of white clover survived the winter. Canada field peas ripened very little seed. Of 40 varieties of potato grown 7 are recommended. The highest yield approached 425 bushels per acre. Seedling potatoes from the Sitka station were also tested. Sugar beets and other root crops gave fair results. All apple trees planted in 1918 had died. Red and black currants produced good crops, but gooseberries and red raspberries froze back considerably. A strawberry bed was killed by ice cap due to lack of drainage. Tartarian honeysuckle and *Rosa rugosa* are recommended. Small fruit plants are being grown for distribution among settlers of the region. The usual hardy vegetables were grown.—*J. P. Anderson.*

1586. RATCLIFFE, GEORGE T. The work of the San Antonio experiment farm in 1919 and 1920. U. S. Dept. Agric. Circ. 209. 39 p. 1922.—The author reports on rotation, tillage, and similar practices; on crops, including cotton, corn, sorghums, small grains, field peas, flax, Rhodes grass, peaches, plums, jujube (the Chinese date, *Zizyphus* sp.), Japanese persimmons, apricot, pecan, citrus, etc., and on cotton root-rot.—*L. R. Hesler.*

1587. REICHELT. Ergebnis eines dreijährigen Anbauversuchs mit zwei Spätkarottensorten. [Results of a 3-year culture test with late carrots.] Mitteil. Deutsch. Landw. Ges. 37: 471. 1922.—The results of tests of 2 late varieties of carrots made at various stations are reported, Long Red Sudenburger giving best yields.—*A. J. Pieters.*

1588. REYNOLDS, MARK H. Farmers' experiment plots. Maize experiments 1921-22. North-western district. Agric. Gaz. New South Wales 33: 703-707. 1 fig. 1921.—Experiments were conducted upon 11 private farms, 20 varieties being used. Minnesota 23 grown at Guyra gave the maximum yield of 61.3 bushels per acre. A limited number of manurial trials were carried out.—*L. R. Waldron.*

1589. REYNOLDS, MARK H. Farmers' experiment plots. Potato experiments, 1921-22. New England district. Agric. Gaz. New South Wales 33: 729-731. 1922.—The experiments were conducted cooperatively with 9 farmers. The variety Factor yielded highest at 8 points. The greatest fertilizer returns were obtained from plots comprising land recently broken from pasture or from land not recently cropped to potatoes. Plots continuously cropped to potatoes without fertilizer did not respond profitably to fertilizer application.—*L. R. Waldron.*

1590. REYNOLDS, MARK H. Fodder crops for dairy farmers. Northern tablelands. Agric. Gaz. New South Wales 33: 725-726. 1922.—The article discusses best fodder crops for the various zones in this district.—*L. R. Waldron.*

1591. RICHTHOFEN, VON. Bodengare unter Berücksichtigung der Stallmistdüngung. [Manuring with stable manure.] Mitteil. Deutsch. Landw. Ges. 37: 670-674. 1922.—The author advocates spreading manure in winter on fall-plowed land. The number of soil bacteria is said to have been increased and the yield of potatoes to have been much improved by this method.—*A. J. Pieters.*

1592. ROSSEM, C. VAN. Bemestings-, nawerkings- en vruchtwisselingsproeven op Java en ter Oostkust van Sumatra. Verslag over den Westmoesson 1918-1919. [Fertilizer, fertilizer after-effect, and crop-rotation tests in Java and the East Coast of Sumatra. Report for the west monsoon 1918-1919.] Dept. Landb. Nijv. en Handel [Nederland.-Indië] Alg. Proefsta. Landb. Mededeel. 5. 109 p. 1920.—Pages 9-16 summarize the results of these tests. The remainder of the publication is devoted to a detailed description of the same tests.—*Carl Hartley.*

1593. ROSSEM, C. VAN. Bemestings-, nawerkings- en vruchtwisselingsproeven op Java en Sumatra. Verslag over den Westmoesson 1919-1920. [Fertilizer, fertilizer after-effect, and rotation tests in Java and Sumatra. Report for 1919-1920.] Dept. Landb. Nijv. en Handel [Nederland.-Indië] Alg. Proefsta. Landb. Mededeel. 10. 119 p. 1921.—This article gives tests of commercial fertilizers, stable manure, and green manures on rice. In addition 6 fertilizer tests with potatoes and 1 with corn are reported; also 5 rotation experiments. A general survey of the results is given in pages 9-16.—*Carl Hartley.*

1594. ROSSEM, C. VAN. Bemestingsproeven in den proeftuin. Verslag over het jaar 1918, tevens samenvatting van de resultaten met die der voorafgaande jaren. [Fertilizer experiments and report for 1918 together with a summary of the results of previous years.] Dept. Landb. Nijv. en Handel [Nederland.-Indië] Alg. Proefsta. Landb. Mededeel. 2. 41 p. 1919.—Extensive comparisons are made of various artificial manures with regard to their effect on the production of rice. In 6 tests calcium nitrate had about the same effect as ammonium sulphate while both were more favorable than Chili saltpeter. Sulphuric acid appeared to have no influence on rice production. Calcium carbonate increased the yield. Chili saltpeter and ammonium sulphate were compared in production of cassava and the results showed that the former used singly or in combination with superphosphate gave the highest yields.—*R. D. Rands.*

1595. ROSSEM C. VAN. Bemestingsproeven in den proeftuin. Verslag over het jaar 1919. [Fertilizer tests in the experimental grounds. Report for the year 1919.] Dept. Landb. Nijv. en Handel [Nederland.-Indië] Alg. Proefsta. Landb. Mededeel. 6. 31 p. 1921.—Experiments at Buitenzorg are reported. The addition of sulphuric acid 5 successive times on the same field, in quantities equivalent to 270, 540, and 740 pounds of ammonium sulphate per acre, has failed to show any definite effects on rice production. With superphosphate 3 or 4 applications, and with ammonium sulphate 4 applications, were more advantageous than the same amounts of these fertilizers added in a smaller number of applications. Calcium carbonate increased rice production. Three years' tests indicate that for cassava, Chili nitrate, either alone or with phosphates, is more valuable than ammonium sulphate used in the same way.—*Carl Hartley.*

1596. RUSSELL, G. A. Peppermint on muck soil. Jour. Amer. Peat Soc. 15⁴: 15-22. 1922.—Peppermint is successfully grown on muck soils in Indiana and Michigan.—G. B. Rigg.

1597. SCHEUERMANN, R. Zur Frage der Ringelkletten in deutschen Wollen. [On the question of bur clovers in German wool.] Mitteil. Deutsch. Landw. Ges. 37: 572-573. 1922.—The author points out that introduced plants do not establish themselves in Germany. *Xanthium spinosum* is said to have entirely disappeared from the vicinity of Döhren during the war when the supply of foreign wool was cut off. The author suggests that pollinating agents are wanting because fertile seed are seldom found on the weeds introduced with wool. Several species of *Medicago*, especially *M. minima*, are mentioned as having been found near wool-cleaning factories. The distribution of this species in Germany is given and it is concluded that there is no danger of this plant becoming a serious pest.—A. J. Pieters.

1598. SCHULTZE, ERNST. Die Zerrüttung der Weltwirtschaft. [The break down of world trade.] 370 p. W. Kohlhammer; Stuttgart, 1922.—Agricultural interests are barely touched upon in the discussion of raw materials. The author is most interested in exchange, railway and steamboat matters, coal, petroleum, industry in general, and trade balances.—A. J. Pieters.

1599. SNELL, K. Die Gruppierung unserer Kartoffelsorten nach bestimmten Typen. [The grouping of our potato varieties according to certain types.] Mitteil. Deutsch. Landw. Ges. 37: 445-446. 1922.—The grouping of varieties by stem and foliage characters is very difficult; a few examples are given. A grouping by tubers has been carried out under the auspices of the Deutsche Landwirtschafts Gesellschaft. In 1914, Schifftan in his "Almanac" made such a grouping, and the present writer in Heft 5 of Arbeit. Forschungsinst. Kartoffelbau has grouped the newer varieties, utilizing the following characters: (1) color of skin (white or colored); (2) color of flesh (white or yellow); (3) form of tuber (round or long); (4) color of light sprout (green, red, or blue violet); (5) color of flower (white, red, or blue violet).—A. J. Pieters.

1600. SNODGRASS, M. D. Report of work at Fairbanks station. Rept. Alaska Agric. Exp. Sta. 1920: 36-48. Pl. 4-5. 1922.—A drought following the dry season of 1919 was severely felt. Romanow and Chogot wheats grown on land that produced 30 and 27 bushels per acre in 1919 produced 6 and 4 bushels respectively. Five other varieties of wheat were grown in test plots. Average yield of wheat on farms in the vicinity was about 15 bushels. Report is made on tests of oat and barley varieties. Buckwheat was a success. Peas were grown for seed, grain for hay. Fourteen varieties of potatoes averaged 82 bushels per acre. Yield of root crops was light. Alfalfa and red clover wintered well being protected by a heavy snowfall. Except red currants, native fruits were abundant. Red raspberries and hybrid strawberries were grown. More than 15 tons of seed grain were distributed among the farmers, mostly by sale or agreement. Cooperative work was carried on.—J. P. Anderson.

1601. STAPLEDON, R. G., R. D. WILLIAMS, KATHLEEN SAMPSON, and T. J. JENKINS. Preliminary investigations with herbage plants. Rept. Welsh Plant Breeding Sta. Univ. Coll. of Wales Aberystwyth 97 p. 1922.—This report covers the results of 3 years' trials with alfalfa, clovers, vetches, and various grasses; growth being discussed under the periods awakening, zenith, gradually waning, rapidly waning, and death. For each species the authors discuss the factors, such as previous cutting, that influence the amount of growth during each period. From a study of flowering in the fall of the seeding year, the authors conclude "that of the species capable of producing heavy Autumn Bites, it is those strains which develop numerous flowering shoots in the seeding year that are most to be desired." Under the heading "Potentiality and Nationality" are reported the success or failure of many species of exotic grasses and legumes, especially clovers, with notes on their probable usefulness in Wales. Notes on fungus diseases are given under each group. Species already more or less widely used in Britain are discussed at greater length, with notes on parasites. The species subject to more exhaustive investigations at Aberystwyth are cocksfoot (*Dactylis glomerata*), Italian and peren-

nial rye grass, a hybrid called "perenital" (*Lolium perenne* \times *L. italicum*), timothy, and tall oat grass. The discussion of the "cocksfoot" and of the rye grasses is especially full, covering the behavior of various strains and nationalities. The author finds that plants of cocksfoot fall into 4 fairly natural growth groups: "dense," "open," "pasture," and "hay." Under clovers, white and red clovers are extensively discussed. The behavior of varieties such as wild white and red clover of various nationalities is reported. In both early and late groups the English red clover gave highest yields, with Chilean 2nd and Canadian 4th. Italian clover proved the most susceptible to anthracnose (*Gloeosporium caulivorum*). There is further a discussion of cyanophoric tests with seedlings and plants of white clover, with reference to the literature. Seed production tests of cocksfoot, perennial rye grass, and timothy are reported. Studies were made and results reported of cross and self-pollination in meadow foxtail, sweet vernal, fine leaved fescues, timothy, rough stalked meadow grass, perennial rye grass, and cocksfoot.—*A. J. Pieters.*

1602. STIEGER. Unsere Pflicht in der Brotversorgung. [Our duty regarding the bread supply.] Mitteil. Deutsch. Landw. Ges. 37: 556-557. 1922.—The author points out that 80-90 per cent of the food value of grains fed to cattle is lost and advocates a more complete use of food grains for direct human consumption.—*A. J. Pieters.*

1603. THATCHER, L. E. Corn and soybeans for silage. Ohio Agric. Exp. Sta. Monthly Bull. 7: 79-81. 1922.—In tabular form accompanied by brief explanation yields of silage from corn alone and from the combination of corn and soy beans in the same hill are given; also drilling and checking methods are compared. Suggestions are made regarding the most advantageous time and method of planting.—*R. C. Thomas.*

1604. THATCHER, L. E. Sunflowers for silage in Ohio. Ohio Agric. Exp. Sta. Monthly Bull. 7: 43-49. 1922.—From the data presented conclusions are not warranted; yet there are indications that in Ohio sunflowers cannot compete with corn for silage. In tabular form are given a comparison of sunflowers and Blue Ridge corn for ensilage, of sunflowers versus corn in drills and hills, a comparison in pounds per acre of dry matter based on a 3-year average yield, also an analysis of fresh cut sunflowers, sunflower silage, and corn silage at the Ohio Experiment Station. The article also includes estimates by a number of farmers who have cooperated in determining the relative value of the 3 forms of ensilage.—*R. C. Thomas.*

1605. THATCHER, L. E. Wheat, cultural notes. Ohio Agric. Exp. Sta. Monthly Bull. 7: 139-143. 1922.—The author discusses important cultural features, such as rate of seeding, date of seeding, and preparation of seed bed. The discussion is supported by tables showing the result of experimental work.—*R. C. Thomas.*

1606. THOMAS, GEORGE. The development of institutions under irrigation; with special reference to early Utah conditions. xi+293 p. Macmillan Co.: New York and London, 1920.—The author discusses the development of irrigation institutions in Utah and undertakes to show how the Mormons coped with the institutional problems of irrigation. Of the first canals the smaller were individual or partnership affairs but the larger were community or cooperative undertakings, which when completed were controlled by a watermaster elected by the people. Soon after the settlement of the territory the legal control of the canal was given to the county courts and later to the county selectmen. Numerous cases tried before the county courts, district courts, and supreme court are cited and discussions given. Various legislative features bearing on irrigation such as the Carey Act and the Reclamation Act are discussed in detail. Considerable attention is given to the development of some of the larger projects within the state.—*H. L. Westover.*

1607. THOMPSON, G. E., and C. J. WOOD. Growing cotton in Arizona. Arizona Agric. Exp. Sta. Bull. 90. 265-275. 1919.—This general discussion refers primarily to American Egyptian cotton.—*Herbert C. Hanson.*

1608. THORN, C. E. Fertilizing the wheat crop in Ohio. Ohio Agric. Exp. Sta. Monthly Bull. 7: 112-121. 1922.—The experiments reported cover all the principal Ohio soil types, and several of the trials have been continued sufficiently long to cover a full cycle of climatic change. On every soil in Ohio where wheat is grown in a rotation of clover, profitable returns will doubtless be realized from a moderate dressing of acid phosphate. On the average soil, muriate of potash will give more than sufficient increase to cover its cost, although there are exceptions, and on a few soils nitrate of soda may be used at a profit provided the demand of the soil for phosphorus has been supplied.—*R. C. Thomas.*

1609. TORNAU, OTTO. Ein Versuch über den Einfluss der Kornschwere des Saatgutes auf den Ertrag bei Hafer. [An experiment on the influence of the weight of seed upon the yield in oats.] Jour. Landw. 69: 205-213. 1921.—The results show that yields were about the same whether large or small grains were planted. On the other hand, the large grains showed superiority in development of the growing plant.—*F. M. Schertz.*

1610. WEBER, HERMANN. Die praktische Kartoffelzüchtung in Kovarce und Udvarnok (Slowakei). [Practical potato breeding in Czechoslovakia.] Oesterr. Zeitschr. Kartoffelbau 2: 21-24. 1922.—The production of new strains and varieties by selection and by hybridization is discussed, and an outline of the author's procedure in producing cross bred seed and care of seedlings and the selection and testing of the latter is given. By transplanting seedlings twice before setting in the field they develop larger root systems. It is stated that by this treatment 1-year seedlings attain size and yield comparable to those of plants grown from tubers.—*F. Weiss.*

1611. WENHOLZ, W. Soil improvement for maize. Part I. Manures and fertilizers. New South Wales Dept. Agric. Farmers' Bull. 134. 36 p. 1920. [See Bot. Absts. 7, Entry 60.]

1612. WENHOLZ, H. The cultivation of maize. New South Wales Dept. Agric. Farmers' Bull. 125. 43 p., 13 fig. 1919.—This bulletin describes in popular manner the preparation of the soil, planting, and after cultivation and treatment. Varieties of maize are not discussed. Desuckering a crop at Bathurst resulted in a loss of 21 bushels of grain per acre over the control. Detasseling to increase yield is not recommended. "Topping" of maize (removal of the stalk above the cob for the fodder after the grain has begun to set) is not regarded as an economical practice.—*L. R. Waldron.*

1613. WHITE, W. T. Report of work at Kodiak station. Rept. Alaska Agric. Exp. Sta. 1920: 58-63. 1922.—Reports are given on grains and forage plants which are being grown for silage, etc. None of the crops did as well as usual. Silage is also made of sedge (*Carex cryptocarpa*) with small admixture of beach rye (*Elymus mollis*). Between 60 and 65 tons of hay were made from native bluetop (*Calamagrostis Langsdorfii*). Grimm alfalfa, yellow flowered alfalfa (*Medicago falcata*), sweet clovers (*Melilotus alba* and *M. officinalis*), red clover, vetch (*Vicia sativa*), rape, and Canada field peas were grown but did not do well, due largely to an excessive number of cool, cloudy days.—*J. P. Anderson.*

1614. WILLARD, C. J., and H. L. BORST. Scarifying Ohio sweet clover. Ohio Agric. Exp. Sta. Monthly Bull. 7: 62. 1922.—Although it is claimed that Ohio sweet clover seed does not require scarifying, the authors report excellent results with the Ames huller and scarifier. Samples originally germinating at the rate of 31-90 per cent containing from 1 to 43 per cent hard seed before scarification, averaged 81 per cent of germination afterwards. These results were further verified in field tests.—*R. C. Thomas.*

1615. ZIELSTORFF, W. Über Zusammensetzung und Futterwert von eingesäuertem Kartoffelkraut. [On the composition and feeding value of ensiled potato herbage.] Mitteil. Deutsch. Landw. Ges. 37: 693-694. 1922.—Owing to wet weather the herbage on a field of

potatoes grew rank and remained green at the end of September. This herbage was cut and ensiled. Analyses of fresh material and of the silage showed that in the upper layers there was a 38 per cent loss in organic matter and 25 per cent in the lower layers. In feeding tests this silage was used to replace mangels in the standard feed. Potato silage had about the same feeding value as mangels, as shown by total milk production and percentage of butter fat.—*A. J. Pieters.*

1616. ANONYMOUS. Dr. Joel Lunell. *Amer. Midland Nat.* 5: 243-245. *Frontispiece*. 1920.—This reviews the life and significant works, with the names of some of the publications, of this man of very wide interests, including systematic botany.—*Sister M. Ellen.*

1617. ANONYMOUS. Dr. Joseph Trimble Rothrock dead. *Amer. Forestry* 28: 414. 1922.

1618. ANONYMOUS. Franklin B. Hough—a tribute. *Amer. Forestry* 28: 431-432. *Portrait*. 1922.—Notes from the biography of the "Father of American Forestry" are given on the occasion of the centennial anniversary of his birth.—*Chas. H. Otis.*

1619. ANONYMOUS. Obituary notice. *Trans. and Proc. Bot. Soc. Edinburgh* 27: 344-345. 1919.—A brief sketch and appreciation are given of William Brack Boyd (1831-1918), a former president of the Edinburgh Botanical Society.—*Roxana Stinchfield Ferris.*

1620. ANONYMOUS. Referater af fremmed litteratur. [Reference to foreign literature.] *Tidsskr. Planteavl* 28: 176-184. 1922.—This is a collection of abstracts of important foreign agricultural contributions.—*Albert A. Hansen.*

1621. ANONYMOUS. Sir Frederick Moore. *Gard. Chron.* 71: 322-323. 1922.—This article gives an appreciation and brief biographical sketch following Moore's retirement from the directorship of the Royal Glasnevin Botanical Garden.—*P. L. Ricker.*

1622. ANONYMOUS. Scientific activities in the United States; a biologist's view. [Rev. of: CAULLERY, MAURICE. *Universities and scientific life in the United States*. Translated by: WOODS, JAMES H., and EMMET RUSSELL. *xvii + 269 p.* Harvard University Press: Cambridge, Massachusetts; Oxford University Press: London, 1922.] *Nature* 110: 72-73. 1922.—This book "gives a remarkably lucid and sympathetic interpretation of impressions received by the writer during a stay of 5 months in America in 1916, when, as exchange professor of biology at Harvard, he visited many of the principal seats of learning in the United States."—*O. A. Stevens.*

1623. BERNARD, CH., J. J. B. DEUSS, ET AL. Bibliographisch overzicht III. [Bibliographical survey III.] *Dept. Landb. Nijv. en Handel [Nederland.-Indië] Proefsta. Thee Mededeel.* 72. 116 p. 1920.—Seventy-five Dutch reviews of literature of interest in connection with tea culture, which had previously appeared in *Teysmannia*, are classified under culture, diseases and enemies, preparation, and miscellaneous.—*Carl Hartley.*

1624. BISCHOFF, AD. Saatzuchtgenossenschaften. [Seed breeding associations.] *Jour. Landw.* 70: 81-100. 1922.

1625. BOWER, F. O. Obituary notice. *Trans. and Proc. Bot. Soc. Edinburgh* 27: 342-344. 1919.—A brief sketch and appreciation are given of Dr. Robert Chapman Davie (1887-1919).—*Roxana Stinchfield Ferris.*

1626. BROTHERSON, R. P. *The Manse Garden*. Gard. Chron. 71: 320-321. 1922.—Nathaniel Paterson, author of the Manse Garden, was either the grandson or great-grandson of Old Mortality (the subject of a book by Sir Walter Scott) whose real name was Robert Paterson. He was then a minister at Galashiels near Glasgow. The Manse Garden, published anonymously, was very popular, and was written to stimulate garden cultivation. Several quotations from the book on garden procedure are given and comments are made regarding the work.—*P. L. Ricker*.

1627. C[OHEN] S[TUART], C. P. *De legende van het ontstaan der theeplant*. [The legend of the origin of the tea plant.] De Thee 1: 83-85. 1 fig. 1920.—A Dutch translation is given of the Latin account by Engelbrecht Kaempfer (*Amoenitates exoticæ*, Lemgo, 1712) of the legend of the origin of the first two tea bushes from the amputated eyelids of an Indian ascetic. The supposed connection with eye lids was believed by the Jaapnese to explain the effect of tea in preventing sleepiness. This is explained as a case of the signature doctrine.—*Carl Hartley*.

1628. GAGER, C. STUART. *Historical note concerning the Brooklyn Hunt Botanical Garden*. Brooklyn Bot. Gard. Rec. 11: 118-121. 1922.—Quotations are given from the "Second annual address delivered before the Brooklyn Horticultural Society," by the president, John W. Degrauw, Esq., Dec. 6, 1855. The quotations give information (in addition to that given in Brooklyn Bot. Gard. Rec. for October, 1918) concerning the attempt to establish in Brooklyn "The Hunt Botanical Garden," and the complete failure of the plans.—*C. S. Gager*.

1629. GAGER, C. STUART. *The first "botanic" garden in Brooklyn*. Brooklyn Bot. Gard. Rec. 11: 115-118. 1922.—An account is given of the "Horticultural and Botanic Garden of Brooklyn," established in Brooklyn, New York in 1825 by André Parmentier, who came to Brooklyn from Belgium. André Parmentier was a relative of Anthony Parmentier, who is said to have introduced the potato into France. This early Brooklyn garden had an area of 25 acres and offered for sale the surprising number of 242 kinds of apples, 190 pears, 71 cherries, 64 peaches, 85 plums; also 396 varieties of ornamental trees and shrubs, including 200 varieties of roses. André Parmentier died Nov. 27, 1830.—*C. S. Gager*.

1630. GRIEVE, SYMINGTON. *Obituary notice*. Trans. and Proc. Bot. Soc. Edinburgh 27: 339-342. 1919.—This is a sketch and appreciation of Dr. William Watson (1832-1912), president of the Edinburgh Botanical Society from 1897 to 1899.—*Roxana Stinchfield Ferris*.

1631. HAVENHILL, L. D. *The cultivation of medicinal plants*. Trans. Kansas Acad. Sci. 30: 33-39. 1919/21 [1922].—This short historical account calls general attention to a few drugs, including ginseng, mint, hydrastis, camphor, belladonna, digitalis, and echinacea. A plea for the necessity both of cultivation and of interesting people in the subject is included.—*F. C. Gates*.

1632. HEITLAND, W. E. *Agricola, a study of agriculture and rustic life in the Greco-Roman world from the point of view of labour*. x + 492 p. University Press: Cambridge, 1921.

1633. HERTEL, H. *Lensgreve B. Wedell*. Tidsskr. Landokonomi 1922: 493-496. 1 pl. 1922.—This article records the death and life work of Count B. Wedell, one of Denmark's largest landholders and a leading figure in Danish agriculture.—*Albert A. Hansen*.

1634. JENSEN, JOHS. *Beretning fra Statskonsulent Johs. Jensen, Aabenraa*. [Report of state agent Johs. Jensen of Aabenraa.] Tidsskr. Landokonomi 1922: 418-423. 1923.—This report from the government agent stationed in the recovered province Slesvig (Schleswig), returned by Germany to Denmark after the World War, states that under German rule farming in Slesvig was inferior to farming in Denmark, due principally to the fact that the Danes in Slesvig were heavily taxed.—*Albert A. Hansen*.

1635. JEPSON, W. L. *Carex* exploration in California, an historical note. *Erythea* 8: 5-6. 1922.—The history of *Carex* collecting is traced from the date of the earlier expeditions until the present time, with indication of the special region covered by the various collectors.—W. L. Jepson.

1636. KRUIF, PAUL H. DE. Jacques Loeb, the mechanist. *Harper's Mag.* 146: 182-190. 1922.—The writer presents a resumé of Loeb's work and an analysis of his methods of thought.—C. W. Dodge.

1637. LYONS, H. G. Science in Egypt. *Nature* 110: 283-286. 1922.—The development of the various branches of science in Egypt is briefly reviewed.—O. A. Stevens.

1638. MENZIES, DAVID. Dr. Archibald Menzies. *Gard. Chron.* 72: 7. 1922.—Additions are presented to notes published in *Gard. Chron.* Dec. 24, 1921.—P. L. Ricker.

1639. MOORE, FREDERICK W. William Watson, V. M. H. An appreciation. *Gard. Chron.* 72: 30. 1922.—This article gives a brief biographical sketch on Watson's retirement as curator of Kew Gardens.—P. L. Ricker.

1640. ORR, JOHN. A short history of British agriculture. 96 p., illus. Oxford University Press: London. 1922.—This book devotes a chapter to the story of how men became farmers, considers the history of the art of growing grain, and gives briefly the agricultural history of Britain. The rise of the manor system under William the Conqueror, its decline, the establishment of the landlord-tenant system, and the beginning of modern farming are described. The influence of agricultural literature is traced, beginning with the writing of Walter of Henly in the 13th century. The author tells of the establishment of the first Board of Agriculture in 1793, its effect, and the initial step toward giving farmers a scientific education in a systematic way by the employment in 1803 of Sir Humphrey Davy to lecture on agricultural chemistry. The enactment of important agricultural legislation is described. [See also Bot. Absts. 12, Entry 1645.]-Mary R. Burr.

1641. PARKER, JOHN H. A review of literature on the rusts of oats, with notes on their distribution in the United States. *Trans. Kansas Acad. Sci.* 20: 71-118. 1919/21 [1922].—This is an extended review of 52 cited papers, published before 1916, dealing in part at least with the 2 rusts of oats, *Puccinia Lolii* Niels. f. sp. *Avenae* (crown or leaf rust of oats) and *Puccinia graminis* Pers. f. sp. *Avenae* Erikss. and Henn. (black stem rust), to which is added a series of extracts from answers to a questionnaire sent to each state agricultural experiment station and to each cereal field station of the U. S. Department of Agriculture in February, 1916.—F. C. Gates.

1642. PAYNE, C. HARMON. The history of the moss rose. A critique. *Gard. Chron.* 72: 49, 69-70, 84, 93, 108, 124, 135. 1922.—Comments are presented on a previous article by Major Hurst [see Bot. Absts. 11, Entry 267].—P. L. Ricker.

1643. RICHARDSON, A. E. V. The practical value of agricultural education. *Jour. Dept. Agric. Victoria* 18: 577-586. 1920.—This is an account of agricultural education, the experiment stations, and extension work in America with the applications that should be made for Victorian (Australia) conditions.—Wm. E. Lawrence.

1644. RIDDELL, WILLIAM. The pharmacopeia of another botanical physician. *Trans. and Proc. Bot. Soc. Edinburgh* 28: 1-23. 1920.—An abstract of *The Vegetable Family Physician* by Samuel B. Emmons (Boston, 1836), a follower of the Thomsonian School of Medicine, is given.—Roxana Stinchfield Ferris.

1645. RUSSELL, E. J. The history of British agriculture. [Rev. of: (1) ERNLE. *English farming: Past and present*. 3rd ed., xvi + 504 p. Longmans, Green and Co.: London, 1922.

(2) ORR, JOHN. A short history of British agriculture. 96 p. Oxford University Press: London, 1922 (see Bot. Absts. 12, Entry 1640).] Nature 110: 204-205. 1922.—This edition of the 1st book differs from the previous one in that it contains a chapter on the war farming of 1914-1918. The 2nd book will be very useful to teachers of agriculture.—O. A. Stevens.

1646. SCHRAMM, J. R. The abstracting and indexing of biological literature. Science 56: 495-501. 1922.

1647. SETCHELL, WILLIAM ALBERT. Aboriginal tobaccos. Amer. Anthropol. 23: 397-414. Pl. 3. 1921.—The author has grown seed of tobaccos still in use by various Indian tribes of North America and has studied the geographical distribution of the various species of *Nicotiana*: *N. Tabacum* L. occurring from Brazil to Mexico; *N. rustica* L. used east of the Mississippi River; *N. Bigelovii* (Torr.) Watson and its relatives used in California, Oregon, and North Dakota; *N. attenuata* from Arizona to British Columbia; and *N. trigonophylla* in the Southwest. The author concludes that the distributional evidence points toward an American home for the tobacco plant.—C. W. Dodge.

1648. TONI, G. B. DE. Francesco Baglietto. Nuova Notarisia 33: 32-43. 1922.—This is a biographical and bibliographical sketch of the well-known Italian lichenologist and mycologist and "the last pupil of the illustrious Prof. Giuseppe De Notaris." Baglietto was associated with De Notaris and Cesati in issuing the Erbario Crittogamico Italiano. He was born at Voltri in 1826 and died in Genoa Feb. 24, 1916.—Marshall A. Howe.

1649. WAKSMAN, SELMAN A. Enzymes of microorganisms. Absts. Bact. 6: 265-299, 331-360. 1922.—A bibliographic and historical review is represented with citations to 957 papers bearing on the subject.—D. Reddick.

1650. WALCOTT, C. D. The new building of the National Academy of Sciences, U. S. A. Nature 110: 120-122. 1 fig. 1922.

1651. WALKER, K. C. Bibliography and research. Science 56: 418. 1922.

1652. WIENER, LEO. Africa and the discovery of America. Vol. II. xxi + 287 p., 27 pl. Innes & Sons: Philadelphia, 1922.—References to the early literature regarding cotton are given, from the inscriptions of Sennacherib to Theophrastus. Philological evidence is presented that cotton originated in Assyria and India and that it was not introduced into Egypt or Europe until the Arabic conquest. The author regards the statements in Pliny, other than those copied from Theophrastus, as largely interpolations of a much later date. The author suggests that if the accounts of Columbus and the early explorers are correct, *Bombax ceiba* rather than *Gossypium* was the plant meant by "cotton." Since Columbus brought seeds of a number of plants on his 2nd voyage, it is probable that he imported cotton, a crop perhaps new to the Indians since they were so reluctant to cultivate it. Most of the native cloth was made from the maguey. Cotton culture in Mexico is discussed in detail with a survey of all available references in 16th century literature. In considering the antiquity of cotton in Peru, the author criticises severely the attempts to base chronology on guano deposits. He suggests that cotton was introduced at the Conquest by the negro overseers. Evidence is given that the presence of cotton in graves is no safe criterion of its antiquity.—In discussing the origin of tobacco, the author quotes widely to show the use of fumigations and smoking in ancient and mediaeval medicine. Smoking for pleasure and the "smoke vender" are discussed historically and philologically. There are presented many references to the cultivation of tobacco in Africa and America, and to its use by the natives, both as a medicine and in pursuit of pleasure. The introduction of *Nicotiana* to Europe and its spread are discussed in great detail. The botanical arguments are carefully presented as are also the archaeological data. The author concludes that tobacco was probably of African origin, and brought to America from the Mandingo country in the centuries immediately before the voyages of Columbus. [See also Bot. Absts. 11, Entry 1075].—C. W. Dodge.

1653. WIENER, LEO. *Africa and the discovery of America*. Vol. III. xxi + 402 p., 41 pl. Innes & Sons: Philadelphia, 1922.

BOTANICAL EDUCATION

C. STUART GAGER, *Editor*

ARTHUR H. GRAVES, *Assistant Editor*

(See also in this issue Entries 1622, 1632, 1637, 1640, 1643, 1645, 1978)

1654. ANONYMOUS. *The Royal Botanic Society's gardens*. Nature 110: 185-187. 1 fig. 1922.—This is a brief review of organization and work. The figure is an aerophoto of the grounds.—O. A. Stevens.

1655. ANONYMOUS. *Plant morphology and physiology*. [Rev. of: DIXON, H. H. *Practical plant biology: A course of elementary lectures on the general morphology and physiology of plants*. xi + 291 p. Longmans, Green and Co.: London, 1922.] Nature 110: 274-275. 1922.—This book comprises 30 lectures treating a wide range of plant types from unicellular forms to flowering plants. Outstanding features are the interest and charm of the author's style, and the wide use of data from physics and chemistry.—O. A. Stevens.

1656. ANONYMOUS. [Rev. of: SKENE, M. *Common plants*. (Common Things Series.) 271 p. 26 pl. Andrew Melrose: London, no date.] Nature 110: 177. 1922.—This book is said to be a very readable account of the various problems and achievements of plant study. [See also Bot. Absts. 11, Entry 1085.]—O. A. Stevens.

1657. BÜNGER. *Die Ausbildung des Landwirtschaftslehrers*. [The training of agricultural teachers.] Jour. Landw. 70: 101-108. 1922.

1658. CLUTE, WILLARD N. *Botany for beginners III*. Amer. Bot. 28: 102-106. 1922.

1673. ANONYMOUS. **Important forest trees of the eastern United States.** U. S. Dept. Agric. Dept. Circ. 223. 11 p. 1922.—This is a key to the common kinds of trees (reprinted from U. S. Dept. Agric. Bull. 863) and a table with remarks giving the names and range of 100 important eastern forest trees.—*L. R. Hesler.*

1674. ANONYMOUS. **Preserve the national parks.** *Canadian Field Nat.* 36: 51-52. 1922.—The public should be kept informed of apparently innocent commercial projects which may be used for the fullest exploitation of the natural resources of parks.—*W. H. Emig.*

1675. ANONYMOUS. Redogörelse för Verksamheten vid Statens Skogsförsöksanstalt under år 1920. [Annual report of the activities of the Swedish forest experiment station, 1920.] Meddel. Statens Skogsförsöksanst. 18: 329-340. 1921.—The activities of the various departments are discussed by their respective heads, as follows: Forest management, GUNNAR SCHOTTE, Director; natural science, HENRIK HESSELMAN; forest entomology, IVAR TRÄGÅRDH; natural reproduction in Norrland, EDVARD WIBECK. The report is followed by a similar one covering the year 1921.—G. A. Pearson.

1676. ANONYMOUS. Silvicultural notes. Indian Forest. 48: 401-404. 1922.—Natural regeneration of Haldy, *Adina cordifolia*, was secured only after heavy cutting and slash fires and did not follow any cutting without the aid of fire. A very brief annotated yield table for 4 sites of sal in the United Provinces is given, the site classes being based on average height of dominant trees.—E. N. Munns.

1677. ANONYMOUS. Tests with silver fir for use as sleepers. Indian Forest. 48: 316-327. 1922.—Wood tests of *Abies pindrow* with American Douglas fir (*Pseudotsuga taxifolia*) show that there is little difference in the strength or character of the woods. Durability tests have not yet been run.—E. N. Munns.

1678. ANONYMOUS. The national forests of New Mexico. U. S. Dept. Agric. Dept. Circ. 240. 21 p., 7 fig. 1922.

1679. ANONYMOUS. Trade names for Indian timber. Indian Forest. 48: 135-141. 1922.—A list of the accepted common names is given for 145 Indian timber species.—E. N. Munns.

1680. ANONYMOUS. Your national forests. Amer. Forest. 28: 276-277. 1922.—This editorial briefly summarizes the national forest resources of the U. S. A., their extent, value, yield in lumber, and relation to grazing, water power, and recreation.—Chas. H. Otis.

1681. ANONYMOUS. [Rev. of: GAMBLE, J. S. A manual of Indian timbers; an account of the growth, distribution, and uses of the trees and shrubs of India and Ceylon, with descriptions of their wood-structure. Reprint of 2nd ed. with some additions and corrections. xxvi + 868 p., 20 pl. Sampson Low, Marston and Co.: London, 1922.] Nature 110: 276. 1922.

1682. ANONYMOUS. [Rev. of: STONE, HERBERT. A guide to the identification of our more useful timbers: Being a manual for the use of students of forestry. viii + 52 p., 3 pl. University Press; Cambridge, 1920]. Nature 110: 276. 1922.—[See also Bot. Absts. 7, Entry 764; 11, Entry 10.]

1683. ANONYMOUS. [Rev. of: STONE, HERBERT. A text-book of wood. vii + 240 p., 41 pl. Rider and Son: London, 1921.] Nature 110: 73-74. 1922.—This book is intended for advanced students. It contains some good photographs of wood structures, but many errors of various kinds.—O. A. Stevens.

1684. ASHE, W. W. The creation of the eastern national forests. Amer. Forest. 28: 521-524. 3 fig., 1 map. 1922.

1685. BEESON, C. F. C. The beehole borer of teak: a preliminary report on the ecology and economic status of *Duomitus ceramicus* in Burma. Indian Forest Rec. 8²: 1-105. Pl. 1-6, diagr. 1-3. 1922.—The beehole borer causes severe losses in growth and in the stand. Vigorous trees apparently are more often attacked than the suppressed stand. The average number of holes per tree is directly proportional to the girth. This is due to the more successful development of the insect larvae with rich food supplies. Fire does not appear to be a controlling agent, but thinnings reduce the attack considerably.—E. N. Munns.

1686. BERGER, A. *Die Arbeitsteilung der Tayloristischforstlichen Arbeitsgemeinschaft.* [The "Taylor System" in forest industry.] Wien. Allg. Forst u. Jagd Zeitg. 40: 55-56. 1922.—The author discusses the principles of the system and urges forest owners to acquire greater familiarity with them.—*F. S. Baker.*

1687. BLANDFORD, H. R. *Teak as an even-aged crop.* Indian Forest. 48: 429-431. 1922.—Teak should be thinned early to a wide spacing as later it does not respond to changes in growth conditions. This should be reflected in wider spacing at the time of planting and underplanting with other species of commercial value, which as yet have not been tried. Bamboo as an understory does not produce sufficient revenue.—*E. N. Munns.*

1688. BORTHWICK. *Forest protection.* [Abstract.] Rept. British Assoc. Adv. Sci. 1921: 451. 1921.

1689. BRANDT. *Auffrieren von Nadelholzkulturen.* [Frost-heaving of planted conifer stock.] Deutsch. Forstzeitg. 37: 494-495. 1922.—Damage to uncovered plants was about 80 per cent; plants covered with needle-straw, moss, and rye chaff all escaped; with a covering of heather, pine, and oak twigs, the loss was about 5 per cent, and with coarse sand 10 per cent.—*W. N. Sparhawk.*

1690. BRODERICK, J. J. *England's forestry problem.* Amer. Forest. 28: 341-342. 1922.—In this speech by the commercial counsellor of the British Embassy on the occasion of the acceptance of a gift of Douglas fir seed to Great Britain, the forest policy of England is reviewed.—*Chas. H. Otis.*

1691. C., S. *"Geimpftes" Holz.* ["Inoculated" wood.] Deutsch. Forstzeitg. 37: 464-465. 1922.—Reimann has patented a method for coloring common woods to resemble various cabinet woods and to imitate their grain.—*W. N. Sparhawk.*

1692. CHAMPION, F. W. *"La methode du contrôle" for selection forests.* Indian Forest. 48: 349-364. 4 graphs. 1922.—The method of control, a management plan, was put into limited practice in Switzerland to produce the greatest value in small quantities of material of highest value. The basis is a study of the diameter growth during the entire life of the stand as an indication of its growth and health. Theoretically the method is an ideal form of management, but it is impossible in practice on any but very small areas and then only by well trained foresters.—*E. N. Munns.*

1693. CHAMPION, F. W. *The femelschlag system or the system "by coupes jardinatoires."* Indian Forest. 48: 115-127. 5 fig. 1922.—This system is used in mixed forests of beech, spruce, and fir where the age classes are unevenly distributed and where there is no definite felling cycle. In effect is a thinning rather than a cutting, releasing reproduction and advance growth whenever necessary, and securing high quality wood. The chance of failure in securing reproduction is minimized, the method is elastic, and is adapted to tolerant trees.—*E. N. Munns.*

1694. CHAMPION, H. G. *Note on the death of chir (Pinus longifolia) poles in the Almora plantations of Kumaon.* Indian Forest. 48: 168-173, 232-246. Pl. 9. 1922.—Extensive dying off of chir in plantations has made it imperative to combat this death rate. The high mortality nullifies attempts to complete stocking of poorer areas, for in 3 years' time 25 per cent of the dominant trees were killed. Control measures recommended are the removal of suspected trees and the burning of all resulting debris.—*E. N. Munns.*

1695. CHAPMAN, H. H. *Forest mensuration.* xii + 553 p. John Wiley and Sons: New York; Chapman and Hall, Ltd.: London, 1921.—This text book is a successor to Graves' Forest Mensuration. It discusses the measurement of the volume of felled timber; the meas-

urement of standing timber; and the growth of trees, forest stands, and forests. Part 1 shows the relation of the cubic contents of logs and other measurement to the contents as expressed in terms of products. Part 2 presents a complete analysis of the art of timber estimating as practiced in every timber region of the U. S. A. Part 3 aims to systematize the principles and problems that are encountered in studying tree growth. The book contains 89 tables. A 10 page appendix on lumber grades and rules follows the text and a 13-page appendix on the measurement of piece products outlines practical suggestions.—[See also Bot. Absts. 12, Entry 398.]-T. C. Harbeson.

1696. CHEYNEY, E. G. *The passing of an industry. An epic of the great American forest.* Amer. Forest. 28: 323-338. 24 fig., 1 map. 1922.—A popular résumé is presented of timber resources and logging industries in the U. S. A. and their historical background from the time of the landing of the Pilgrims to the present day.—Chas. H. Otis.

1697. COOPER, H. L. *Notes on some Assam rain forests.* Indian Forest. 48: 131-132. 1922.—The rapid rate of decay and the weight of the climbers aiding in breakage and wind-falls are thought to be the reasons why trees in rain forests do not attain great size.—E. N. Munns.

1698. CRIDDLE, NORMAN. *The relation of wild life to agriculture.* Canadian Field Nat. 36: 47-49. 1922.—With the advent of civilization, followed by cultivation, the natural balance became changed. A restoration of the former balance might be accomplished by the establishment of wild life sanctuaries and the planting of trees and berry-bearing shrubs near farm buildings.—W. H. Emig.

1699. CUNLIFFE, N. *Height growth of trees.* Quart. Jour. Forest. 16: 274-275. 1922.—Vigorous young trees averaging $2\frac{1}{2}$ m. were measured every 2 weeks for height growth during the summer of 1921 to determine effect of climatic factors. Corsican pine and western yellow pine (*Pinus ponderosa*) grew most rapidly at the end of May; Sitka spruce, Douglas fir, and lowland white fir (*Abies grandis*) in the latter part of June. Growth of all these species started the end of April and ceased in July or early August. In European and Japanese larch the whole growth period was 2-4 weeks later than in the other conifers, and growth was more regularly distributed over the whole period. Beech differed markedly from the conifers in that it grew very rapidly during May and only slowly during June and the early part of July. The maximum daily increment of the most vigorous trees, varied from 4.7 mm. for western red cedar (*Thuja plicata*) to 33.5 mm. for beech. The former showed a slight winter growth and also a small growth of the previous year's shoots. In Corsican pine and Sitka spruce temperature was more important than all other factors combined in determining fluctuations in growth rate. The same was true for larch when the mean shade temperature did not rise about 66°F., above 66 growth was depressed. An increase in mean air temperature during the entire growing period decreases the annual growth of Corsican pine while a rise in the mean daily temperature increases the daily increment. Annual increment proved inversely related to mean soil temperature at the 6-inch depth for May and June. Rainfall of the growing period appeared more important than that of the previous winter.—C. R. Tillotson.

1700. DINGLER, MAX. [Rev. of: STELLWAAG, F. *Die Schmarotzerwespen (Schlupfwespen) als Parasiten.* (The parasitic wasps.) Beih. Zeitschr. Angew. Entomol. No. 6. 1921.] Forstwiss. Centralbl. 44: 32-34. 1922.—This is the first comprehensive biological treatise on a group of insects very important in agriculture and forestry. The author includes in the group all those insects—8 families and certain species of 2 others—which show true parasitism.—W. N. Sparhawk.

1701. EBERHARD, J. *Der Schirmkeilschlag und die Langenbrander Wirtschaft.* [The shelterwood-wedge cutting and the Langenbrand method.] Forstwiss. Centralbl. 44: 41-54, 103-109, 137-150. 5 fig. 1922.—The author discusses his system of silviculture and replies to

criticisms by C. Wagner. The essentials of the method are: (1) light cuttings over the whole area to secure reproduction of tolerant species, followed at frequent intervals by other light cuttings to keep the young growth in good condition; (2) gradual removal of mature timber by wedge-shaped cuttings, which are enlarged a little each year until the whole area is covered. The article is accompanied by a bibliography of 30 titles.—*W. N. Sparhawk.*

1702. ECKSTEIN. *Der Buchenspringrüsselkäfer Orchestes fagi* und seine wirtschaftliche Bedeutung. [The beech weevil, *Orchestes fagi*, and its economic significance.] Deutsch. Forstzeitg. 37: 435-437. 1922.—The life history and habits of this leaf-eating beetle are discussed. Although attacking only beech in the forest, outside the forest it eats several cultivated trees and crops. The leaves, punctured along the midrib for the deposition of eggs, exude a "leaf honey", sought by bees.—*W. N. Sparhawk.*

1703. ESCHERICH, K. [Rev. of: DECOPPET, M. *Le haneton. Biologie, apparition, destruction.* (The May beetle.) 130 p., 5 charts, 42 maps. Lausanne and Geneva, 1920.] Forstwiss. Centralbl. 44: 74-76. 1922.—Decoppet's monograph contains much valuable information about the May beetle in Switzerland, especially regarding control methods. He believes that the differences in period of development of the beetle in different localities are due to hereditary characteristics rather than to climatic factors. This theory is directly opposed to the views of others, especially Zweigelt.—*W. N. Sparhawk.*

1704. EYSEL, JOH. *Der erste österreichische Almwirtschaftstag und der Weidwald.* [Alpine agriculture and grazing forests.] Wien. Allg. Forst u. Jagd Zeitg. 40: 61-62. 1922.—Present economic conditions make alpine grazing an important business. It is leading to the destruction of high altitude forests. The importance of maintaining a forest cover is recognized. Legal difficulties are in the way of a proper combined grazing and forest management. Present law recognizes only grazing lands (alpine meadows) and timberlands, and not a combination.—*F. S. Baker.*

1705. FABRICIUS, L. *Holzartenzüchtung.* [Breeding of forest trees.] Forstwiss. Centralbl. 44: 86-103. 1922.—Some attention is now given to the selection of seed adapted to sites where it is to be grown. The principles and methods of plant-breeding are briefly outlined, and the possibility of applying the same methods to developing new strains of tree species is discussed. The author regards this as a promising field for research.—*W. N. Sparhawk.*

1706. FABRICIUS. [Rev. of: ANDÉS, LOUIS EDGAR. *Die technischen Vollendungsarbeiten der Holz-Industrie.* (The technique of finishing wood.) 6th ed., 253 p., 54 fig. Vienna and Leipzig, 1920.] Forstwiss. Centralbl. 44: 38-39. 1922.—This book full of helpful suggestions on how to polish, color, and otherwise finish woods for use in furniture and decorative work, is extremely important to German wood-working industries.—*W. N. Sparhawk.*

1707. FABRICIUS. [Rev. of: GAYER, SIG. *Die Holzarten und ihre Verwendung in der Technik.* (Kinds of wood and their utilization.) 2nd ed., 278 p., 47 fig. Leipzig, 1921.] Forstwiss. Centralbl. 44: 39. 1922.—This book, written especially for the wood-working industries, covers the structure and identification of wood, chemical composition of wood and bark, technical properties and defects, uses of individual species, and utilization of by-products and wood-waste.—*W. N. Sparhawk.*

1708. FABRICIUS. [Rev. of: THENIUS, GEORG. *Das Holz und seine Destillations-Produkte.* (Wood and products of its distillation.) 3rd ed., 493 p. Vienna and Leipzig, 1921.] Forstwiss. Centralbl. 44: 37-38. 1922.—The book is regarded as an up-to-date work on dry distillation of wood.—*W. N. Sparhawk.*

1709. FEUCHTINGER. *Holzfüllung und Rodung mit mechanischen Vorrichtungen oder mittelst Springstoffen (Kultursprengungen)*. [Felling and clearing with mechanical apparatus or explosives.] Wien. Allg. Forst u. Jagd Zeitg. 40: 157-159, 169-171, 175-177, 183. 1922.

1710. GLASSON, A. K. *Regeneration of sal in the low level forests of the Duars*. Indian Forest Rec. 8⁴: 1-17. Pl. 1. 1922.—Old methods of regeneration failed to produce successful establishment of sal. By permitting agricultural use of the land and the care and cultivation of the young sal trees in rows or mounds, successful plantations have been established. Two agricultural crops can be raised before the sal interferes.—*E. N. Munns*.

1711. GROSS, J. *Zur Weidezucht*. [Basket-willow growing.] Möllers Deutsch. Gärtnerzeitg. 37: 209. 1922.—Willow twigs are in demand for the basket industry. From 1914 to 1918 many plantations were ruined by an excessive demand for baskets for large ammunition. The planting of cuttings of 25 cm. length of *Salix dasyclades*, *S. americana*, and *S. viminalis regalis* is recommended. The soil should be loosened to a depth of 50-60 cm. and the rows planted 50 cm. apart.—*J. C. Th. Uphof*.

1712. GUTHRIE, J. D. *Alaska's interior forests*. Amer. Forest. 28: 451-455. 7 fig. 1922.—The forests of interior Alaska are practically confined to the great basins of the Yukon and Kuskokwim rivers. Their area is estimated at 80-150 million acres. The principal trees are white spruce, white birch, balsam poplar, black cottonwood, aspen, black spruce, and tamarack or larch. Of these white spruce is by far the most important. Even with the most careful handling these forests will probably not fully supply the future needs of the country, although the rate of growth is fairly rapid. The species composing the interior forests are admirably suited for pulp. The chief uses of lumber have been for flume and sluice boxes, boat building, and houses and buildings. Considerable loss has occurred through forest fires. Seven items are considered by the writer as a part of any plan for forest protection in interior Alaska.—*Chas. H. Otis*.

1713. HAWLEY, R. C. *The practice of silviculture: with particular reference to its application in the United States*. xi + 352 p. John Wiley and Sons, Inc.: New York; Chapman and Hall, Ltd.: London, 1921.—This book treats of silvicultural practices applicable to forest conditions in America. It considers the establishment and development of forest stands, intermediate slash disposal cuttings, and the protection of stands against such destructive agents as fire, insects, fungi, animals, and wind. At the end of each of the 20 chapters appears a list of references, a total of 311. An appendix gives a full list of silvicultural terms and definitions, as compiled by a committee of the Society of American Foresters.—*Henry B. Phillips*.

1714. HOFINGER, ALOIS. *Der Taylorismus in der Forstwirtschaft—die Förderung des Tages*. [The "Taylor System" in forestry.] Wien. Allg. Forst u. Jagd. Zeitg. 40: 73. 1922.—This is an appeal for the application of the "Taylor System" (time studies of fundamental motions) in lumbering and forestry.—*F. S. Baker*.

1715. HOLSTE, GEORG. *Fichtenzapfen- und Fichtensamenbewohner*. [Insects infesting spruce cones and seed.] Forstwiss. Centralbl. 44: 69-74. 6 fig. 1922.—This is a summary of the results in investigations by Holste, Seitner, and Trägårdh. Of 44 species identified by the author in spruce cones from upper Bavaria, 3 are injurious to seed, 13 to cones, 15 are parasites of these injurious insects, 3 feed on molds and 3 on insects, 3 are mites, 2 are bugs occupying the cones as winter quarters, and the others are accidental. Several of the more important species are described.—*W. N. Sparhawk*.

1716. HUTCHINSON, W. *The eyes of the forest*. Amer. Forest. 28: 461-468. 15 fig. 1922.—This article describes the evolution of the fire lookout as developed by the U. S. Forest Service.—*Chas. H. Otis*.

1717. ILLICK, J. S. *The beeches*. Amer. Forest. 28: 546-551. 7 fig. 1922.

1718. ILLICK, J. S. The birches. Amer. Forest. 28: 355-364. 18 fig., 1 map. 1922.—This is a popular description of the common birches, their habits, characteristics, and uses.—*Chas. H. Otis*.

1719. ILLICK, J. S. The white oaks. Amer. Forest. 28: 586-592. 13 fig. 1922.—This is a popular consideration of the common white oaks,—*Quercus alba*, *Q. bicolor*, *Q. macrocarpa*, *Q. minor*, *Q. Prinus*, *Q. Muhlenbergii*, *Q. lobata*, and *Q. Garriana*.—*Chas. H. Otis*.

1720. KEARNEY, T. H. Tropical forests and their resources in French colonies. [Rev. of: BERTIN, A. Mission d'études forestières envoyée dans les colonies françaises par les ministères de la guerre, de l'armement et des colonies. Vol. I-V. Maps, diagr., illus. Émil Larose; Paris, 1918-1920.] Geog. Rev. 12: 512-513. 1922.

1721. LARSEN, J. A., and C. C. DELAVEN. Climate and forest fires in Montana and Northern Idaho, 1909 to 1919. Monthly Weather Rev. 50: 55-68. 13 fig. 1922.—The region was divided into 7 broad climatic and topographic sections for comparison. The area burned over varies greatly for the various sections, the average ranging from 234 acres in northern Idaho to 100 acres in eastern Montana. The greater hazard is due to differences in climatic conditions, especially rainfall, on the east and west slope of the Continental Divide. The heavy precipitation in Idaho results in a heavy forest, which in the dry period is subject to heavy losses. The most dangerous weather for forest fires occurs at the time of a succession of high pressure areas over the Pacific Northwest. Forest-fire predictions are as yet unreliable, reliance now being placed upon records of current climatic and fire conditions.—*E. N. Munns*.

1722. LORENZ, HEINRICH. Zollsätze auf die Holzeinfuhr nach Oesterreich für den neuen Zolltarif. [Import duties on wood under the new Austrian tariff.] Wien. Allg. Forst u. Jagd. Zeitg. 40: 127-128. 1922.

1723. MCCALLIE, S. W. Deforestation and erosion. Amer. Forest. 28: 394-396. 3 fig. 1922.

1724. NAGLE, W. Note on shingles made of "Kail" and "Chir" Indian Forest. 48: 328-330. 1 pl. 1922.

1725. NICHOLSON, J. W. Distribution and habit of *Dendrocalamus strictus* and *Bambusa arundinacea* in Orissa. Indian Forest. 48: 425-428. 1922.—The former appears to be confined to a belt with low average humidity in regions where the breezes from the Bay of Bengal are not felt. With increasing humidity, it gradually disappears. Within its range the nature of the soil is the governing factor, the species apparently preferring the physiologically dry soils. Flowering is rather irregular and sporadic, and apparently the tree has been forced from the good to poor soils and sites. *Bambusa arundinacea* prefers the moister sites and better soils, decreasing in importance as drier regions are reached.—*E. N. Munns*.

1726. NIKODEM. Waldbauliche Betrachtungen. [Forest planting observations.] Wien. Allg. Forst. u. Jagd. Zeitg. 40: 123-124. 1922.—The drought of 1921 caused many plantation failures. Success in dry seasons is best attained by planting carefully in large holes. On slopes the trees should be planted with the short roots toward the hill, and the soil around the tree should be left with an inward tilt to catch and hold water.—*F. S. Baker*.

1727. PACK, A. N. Fighting avalanches in the Pyrenees. Amer. Forest. 28: 259-262. 8 fig. 1922.—This is a popular description of afforestation methods, as practised by the French and Swiss governments, for the prevention of damage from avalanches and floods.—*Chas. H. Otis*.

1728. PEARSON, R. S. Results of antiseptic treatment of sleepers. Indian Forest Rec. 91: 1-49. 6 pl., 1 fig. 1922.—After 10 years' testing, the choice of treatment of railroad ties

lies between the Full Cell process using either creosote only or creosote and earth oil together, and Powellizing. The choice between methods is largely one of cost. Further experiments with the Open Cell and Card processes are advocated because of indications. So far, 2 species of *Terminalias*, 3 of *Dipterocarpus*, and 2 of *Pinus* have proved satisfactory. Other woods are being tested.—*E. N. Munns*.

1729. PETERS, J. C. Forest fire protection in Georgia. *Amer. Forest.* 28: 456-459. 5 fig. 1922.—From 1916 to 1921, inclusive, there were reported to the Forest Service 23,000 forest fires, of which 92 per cent resulted from carelessness or from design, and 8 per cent from lightning; 26 per cent were of incendiary origin, 21 per cent from causes unknown, 16 per cent from brush burning, and the remainder were caused chiefly by campers, lumbering, and railroads. About 6,000,000 acres were burned over, causing a money loss to timber and improvements alone of \$5,500,000. Cooperation of federal government and state is suggested for effective fire protection.—*Chas. H. Otis*.

1730. PETRINI, SVEN. Méthode du contrôle. [Method of control.] *Skogsvårdsför. Tidskr.* 19: 249-264. Fig. 1-4. 1921.—The article describes in considerable detail the management of a selection forest in France.—*G. A. Pearson*.

1731. PETRINI, SVEN. Stamformsundersökningar. [Investigations of stem form.] *Meddel. Statens Skogsförsöksanst.* 18: 165-220. Fig. 1-12. 1921.—In this discussion of the form class method of timber estimating the author analyzes the different factors influencing the accuracy of this method and bases his deduction on the results of investigations in stands of Lappland pine. Inaccuracy is apt to result by not getting the correct bark thickness. An ingenious instrument for securing accurate bark measurements is described and illustrated. The graphic methods of determining the average bark thicknesses, form points and form classes are also described and illustrated. Precautions to be taken in the application of this method are pointed out. An English summary is appended.—*Hermann Krauch*.

1732. PEYTON, J. S. State forestry laws of 1921. *U. S. Dept. Agric. Dept. Circ.* 239. 28 p. 1922.

1733. RECKNAGEL, A. B. The future of the American lumber supply. *Amer. Forest.* 28: 611-612. 1922.

1734. RECORD, S. J. Novel trees and forest products. *Amer. Forest.* 28: 481-484. 7 fig. 1922.—The article is popularly descriptive of the royal palm, oyster wood (*Excoecaria lucida*), kiri-gami (*Paulownia*), tree ferns and a peculiar use for them, crotch mahogany, and ash-splint pack baskets.—*Chas. H. Otis*.

1735. RHODES, G. H. Forestry as a business. *Amer. Forest.* 28: 515-520. 5 fig. 1922.—This article discusses the business methods of forest production, taxation, interest charges, etc.—*Chas. H. Otis*.

1736. RICHARDS, E. C. M. West Persia—the wood-famine country. *Amer. Forest.* 28: 579-585. 16 fig. 1922.

1737. RUBNER. Neuere Naturverjüngungsverfahren. [Recent methods of securing natural reproduction.] *Forstwiss. Centralbl.* 44: 1-23. 1922.—Silvicultural methods practised in several mixed forests of spruce, fir, and beech are described. While differing in detail, all emphasize preliminary cutting to secure reproduction and avoidance of conditions which permit sod or dense weeds to occupy the ground and hinder reproduction. Some form of shelterwood cutting over the whole area secures reproduction of the tolerant beech and fir, while strip or border cuttings, normally working from the north or northeast edges, are used to secure the spruce.—*W. N. Sparhawk*.

1738. RUSSELL, P. T. **General notes on nurseries and planting forest trees in the Cinchona plantations.** Mungpoo, Darjeeling District. *Indian Forest*. 48: 224-231. 1 fig. 1922.—Twenty-seven species of native trees have been planted in the past 10 years, and an area of 2,838 acres thus covered. Observations on the care of the trees in nursery and plantations, and methods used, are given.—*E. N. Munns*.

1739. RUSSELL, P. T., L. E. S. TEAGUE, and E. O. SHEBBEARE. **General notes on nurseries and planting in Bengal.** *Indian Forest Rec.* 84: 19-33. Pl. 8-11. 1922.—This summarizes the qualifications of a nursery, nursery practice, and plantings, with notes on 41 Indian species on which some work has been carried out in the nurseries.—*E. N. Munns*.

1740. S. **Die Waldungen von Jugoslawien.** [Forests of Yugoslavia.] *Deutsch. Forstzeitg.* 37: 425. 1922.—Yugoslavia has 7,500,000 hectares of forest, of which 3,162,700 are state forest. Large forest areas remain undeveloped and lack systematic exploitation. Present production is 22,500,000 cubic feet a year, of which 7,000,000 is conifer timber.—*W. N. Sparhawk*.

1741. S., H. W. **Teak regeneration.** *Indian Forest*. 48: 399-401. 1922.—Few teak seedlings result from sowing in the heavy teak cuttings, planted stock being finally used. Burning and the packing of the soil rather than infertile seed are held responsible for the failure. Instead of planting bare spots, it is suggested that better results might come from dibbling in furrows made during the late spring.—*E. N. Munns*.

1742. SCH. **Die Wälder Polens und Rumäniens.** [Forests of Poland and Rumania.] *Deutsch. Forstzeitg.* 37: 403-404. 1922.—The forest areas of the new Rumania and of the new Poland are given by districts and according to the kind of ownership. For Rumania they are classified as to kind of forest,—conifers, oak, beech, and other hardwoods. As a result of the war Rumania tripled her forest area, which is now 7,308,688 hectares. Poland has 9,770,000 hectares of forest, with an annual growth of 14,000,000 cubic m. of saw-timber and 18,000,000 of firewood, and can export about 6,000,000 cubic m. of logs, or 2-3 million cubic feet of sawed timber.—*W. N. Sparhawk*.

1743. SCHMID, F. **Die Bedeutung des Waldes für den Wasserabfluss und sein Einfluss auf die Geschiebeführung der Wildbäche.** [The significance of the forest in run-off and erosion.] *Wien. Allg. Forst u. Jagd. Zeitg.* 40: 146-147, 152-153. 1922.—This is a popular presentation of the work and results of Engler [see Bot. Absts. 9, Entry 710].—*F. S. Baker*.

1744. SECREST, EDMUND. **Forest planting.** *Ohio Agric. Exp. Sta. Monthly Bull.* 7: 144-151. 1922.—The author discusses salient features of forest planting under the following heads: planting stock, planting site, season for planting, spacing distance, methods of planting, direct seeding, care of planting stock, and care of trees after planting.—*R. C. Thomas*.

1745. SHEBBEARE, E. O. **The taungya system in Northern Bengal.** *Indian Forest Rec.* 84: 8-18. Pl. 2-18. 1922.—The employment of field crops to establish the forest crops is known as taungya. Usually a portion of the forest is clear felled in cold weather, the usable material removed, and the debris burned. Then the villagers sow their crops, among which the forest plants are grown in continuous lines or in planting holes spaced about 6 feet apart. From 2 to 3 agricultural crops are secured, depending on the elevation, species, and location. From 1 to 3 acres of this land supports a household.—*E. N. Munns*.

1746. SOMERVILLE, W. **Buds.** *Quart. Jour. Forest.* 16: 121-127. 1922.—The author discusses physiological characteristics of tree buds.—*C. R. Tillotson*.

1747. SONDEREGGER, V. H. **Boys' reforestation clubs.** *Amer. Forest.* 28: 496-499. 4 fig. 1922.

1748. SPESSIVTSEFF, PAUL. Bidrag till Kännedomen om Splintborrarnas Näringsgnag. [Contributions to the knowledge regarding food habits of the European splint beetles (*Eccoptogaster*).] Meddel. Statens Skogsförsöksanst. 18: 315-326. Fig. 1-5. 1921.

1749. SUDWORTH, GEO. B. A new chinquapin. Amer. Forest. 28: 300-301. 1 fig. 1922.—This is a description of *Castanea pumila Ashei* nov. var. a variety of the common chinquapin occurring in the coastal plain of southeastern U. S. A.—*Chas. H. Otis*.

1750. SUTHERLAND, J. Forestry in national and economic aspects. [Abstract.] Rept. British Assoc. Adv. Sci. 1921: 451. 1921.—[See Bot. Absts. 12, Entry 385.]

1751. SYLVÉN, HELGE. Den Skogsteknologiska Forskningen-Erfarenheter och rön från en studieresa i Amerika. [Research in wood technology—notes from a study tour in America.] Skogsvårdsför. Tidskr. 19: 220-246. Fig. 1-9. 1921.—The author has spent 4 years in North America, studying primarily methods of lumbering and utilization. The last year was devoted to a study of technical characteristics and uses of woods. This article outlines the work and organization of the Forest Products Laboratory at Madison, Wisconsin.—*G. A. Pearson*.

1752. THOMAS, C. H. Trees to take the place of those destroyed by chestnut blight. Amer. Forest. 28: 500-501. 1922.—This article mentions chestnut oak, pitch pine, black locust, and other trees which are replacing the chestnut killed by blight.—*Chas. H. Otis*.

(See also in this issue Entries 1543, 1544, 1575, 1578, 1601, 1609, 1610, 1624, 1705, 1873, 1906, 1911, 1912, 1939, 2018, 2066, 2125, 2126, 2149, 2150, 2172, 2174, 2224)

1759. ANONYMOUS. Method employed by the state domains for producing and maintaining their high standard of Sakel cotton. Min. Agric. Egypt [Unnumbered Circ.] 3 p. 1922.—Methods are described of roguing fields at beginning of flowering period and of gathering seed for increase only from typical plants; this, it is claimed, has resulted in great improvement of quality and uniformity of crop.—*T. H. Kearney*.

1760. ANONYMOUS. [German rev. of: KAHN, EUGEN. Über die Bedeutung der Erbkonstitution für die Entstehung, den Aufbau und die Systematik der Erscheinungsformen des Irreseins. (On the significance of the hereditary constitution in the origin, growth and classification of the symptomatic forms of insanity.) Zeitschr. Gesamte Neurol. u. Psychiatrie 74: 69-102. 1922.] Zeitschr. Indukt. Abstamm.- u. Vererb. 29: 219-220. 1922.

1761. ÅKERMAN, Å. Untersuchungen über eine in direktem Sonnenlichte nicht lebensfähige Sippe von *Avena sativa*. [Investigation on a form of *Avena sativa* unable to live in direct sunlight.] Hereditas 3: 147-177. 1922.—In the F₂ of hybrids between Danish Novahavre (Probsteier type oats) and black oats of middle Sweden, seedlings appeared in 1920 which, though normal green at first, yellowed and died in a short time when grown in the bright light of the field. In subdued light ($\frac{1}{4}$ - $\frac{1}{2}$ sunlight) defective plants retain green color and mature seed. This form called *lutescens*, segregated in F₂ in the ratio of about 1 yellow to 70 green; parents and F₁ were all green. Analyses of F₂ and F₃ indicate 63:1 ratio, due to 3 independent homomeric (i.e., duplicate) factors, all recessive to normal green. Novahavre is assumed as unifactorial for chlorophyll and black oats of middle Sweden as bi-factorial.—*C. E. Leighty*.

1762. ALEXANDER, JEROME. The physico-chemical mechanism of mutation and evolution. Science 56: 323-326. 1922.—Solutions of salts and colloids produce remarkable "flowering plants" upon drying. "Auto-protection" due to iso-colloidism is considered. Every substance passes through a colloidal zone before reaching a visibly crystalline state. This colloidal zone interferes with normal crystallization producing feathery forms. It is more surprising that plants and animals should breed true than that they should vary since bio-colloids are so readily affected by salts, H-ion concentration, temperature, actinic and traumatic effects. Specificity of germ plasma is evidently guarded by many factors such as selective adsorption and differential diffusion. Unusual influences must nevertheless occasionally have effect but only beneficial variations survive in nature. Complications due to enzymes, hormones, etc., in higher forms are considered. Simple forms are perhaps best for experiment, but even here are complications for even filterable viruses breed true.—*P. W. Whiting*.

1763. ALVERDES, F. [German rev. of: SIEMENS, H. W. Einführung in die allgemeine Konstitutions- und Vererbungspathologie. (Introduction to the study of general constitutional and hereditary disease.) 229 p., 80 fig. Julius Springer: Berlin, 1921] Zeitschr. Indukt. Abstamm.- u. Vererb. 29: 96. 1922.

1764. BABCOCK, E. B., AND J. L. COLLINS. A case of duplicate genes in *Crepis capillaris* (L.) Wallr. Science 56: 392. 1922.—Results are reported of crossing strains which had more or less pubescence on lower surface of midrib of rosette leaves with one which lacks it. F₁ plants were pubescent and F₂ conformed to ratio, 15 pubescent: 1 non-pubescent. In another cross both 15:1 and 3:1 F₂ populations were secured.—*R. E. Clausen*.

1765. BABCOCK, E. B., AND J. L. COLLINS. Inheritance of glandular pubescence in *Crepis capillaris* (L.) Wallr. Science 56: 392. 1922.—"Bald," which lacks normal glandular pubes-

cence on involucre bracts and pedicels, has been obtained from 6 widely separated geographical locations. Bald condition in these strains was shown to be identical by crossing, and it is a simple recessive to the normal condition.—*R. E. Clausen.*

1766. BAMBER, RUTH C. (MRS. BISBEE.) **The male tortoiseshell cat.** *Jour. Genetics* 12:209-216. 1922.—The author discusses theories of various authors to explain the male tortoiseshell cat. Doncaster's theory that it is a freemartin with complete sex-reversal except for sterility has been tested by examination of 70 pregnant females with a total of 253 kittens. No evidence of confluence of blood vessels was found. Two of the known tortoiseshell males came from matings of tortoiseshell female by yellow male and all sibs in both cases were said to be tortoiseshell and were therefore female. Hence the freemartin theory would be discredited. The possibility is suggested that tortoiseshell male might be due to reversal of "predestined" sex by influences such as those operative in Riddle's pigeons or Goldschmidt's or Harrison's moths; unisexual broods might then be expected. One known tortoiseshell male was produced by black female crossed with yellow male. This female had previously produced only male kittens by different sires. But this mating produced, besides tortoiseshell male, 1 tortoiseshell female and 1 black of unknown sex. Dissection was made of Doncaster's sterile male tortoiseshell, which was found to be typically male. Microscopic examination of left testis showed it to be similar to right, which had been previously reported [*Jour. Genetics* 1915], having large amount of interstitial tissue, well-developed seminiferous tubules, but no spermatozoa. Possibility of breaking down of sex-linkage, which may also account for unexpected black females, is discussed.—*P. W. Whiting.*

1767. BATESON, W. **Evolutionary faith and modern doubts.** *Nature* 109:553-556. 1922.—Variations are usually distinguishable as positive or negative. Negative variations are common, positive ones are rare if they exist at all. Variations causing interspecific sterility are obviously positive ones. Until an unquestionably sterile hybrid is produced by completely fertile parents that have arisen under observation from a single source, we have no acceptable knowledge of the origin of species.—Almost all variations observed at their origin are losses of something. Very few dominant mutations have arisen in *Drosophila*, and these would not be viable in nature. Variations observed in these forms and in domesticated animals and cultivated plants have nothing to do with the origin of species. Cooperation between systematists and geneticists is needed to solve these problems of origin.—*A. Franklin Shull.*

1768. BELLING, JOHN, AND ALBERT F. BLAKESLEE. **The assortment of chromosomes in triploid *Daturas*.** *Amer. Nat.* 56: 339-346. 1922.—The chromosomes of diploid, triploid, and tetraploid plants of *Datura Stramonium* can be grouped into 6 size classes. Diploids show 12 sets of bivalents, and triploids 12 sets of trivalents. In triploids, the distribution of the chromosomes is at random, 2 of each set going to one pole and 1 to the other. Detached chromosomes give rise to microcytes, and non-reduction results in giant pollen grains. The functional egg-cells have 12, 13, or 14 chromosomes, the smaller numbers being most frequent. In triploid progeny, the inheritance of 2 pairs of genes is trisomic. Plants with 1 extra chromosome show 11 bivalents and 1 trivalent, and plants with 2 extra chromosomes show 10 bivalents and 2 trivalents.—*M. E. Farnham.*

1769. BLAKESLEE, A. F., JOHN BELLING, AND J. ARTHUR HARRIS. **The probability established by a culture of given size that a mating is capable of producing only dominant individuals.** *Amer. Nat.* 56: 458-461. 1922.—Tables are given for providing a statistical criterion for the distinction between matings capable of producing only dominant individuals, and those which should give 1:1, 2:1, 3:1, 5:1, 8:1, 11:1, and 35:1 ratios of dominant to recessives. The need of such tables is discussed, and the theory upon which they are based is explained.—*M. E. Farnham.*

1770. BLAKESLEE, A. F., JOHN BELLING, M. E. FARNHAM, AND A. DOROTHY BERGNER. **A haploid mutant in the jimson weed, *Datura Stramonium*.** *Science* 55: 646-647. 1922.—Two

haploid ($1n$) *Datura* plants were secured in an attempt to induce chromosomal irregularities by exposure to low temperatures. Root cells showed 12 chromosomes, the normal (diploid) number being 24. The late prophase and metaphase of the 1st division of pollen-mother cells show 12 unpaired chromosomes only, which undergo a "reduction" into 3 plus 9, 4 plus 8, etc. These reduced groups divide in the 2nd division to form 4 cells, but young pollen grains with less than 12 chromosomes apparently all abort. Non-reduction takes place in some cells, resulting in 2 giant cells from each pollen-mother cell, and apparently forming surviving pollen grains equal in size to those from diploid plants. The haploid *Datura* is a new type among flowering plants since it is a sporophyte with the somatic chromosome number characteristic of the gametophyte, and since the chromosomes undergo a process of reduction without synap-
tic mates.—*J. Lincoln Cartledge.*

1771. CASTLE, W. E. The Y-chromosome type of sex-linked inheritance in man. *Science* 55: 703-704. 1922.—The condition in man called webbed toes is found only in males, and was reported to be transmitted from father to son, through 4 generations, independently of the female line of descent. It therefore has the distribution in heredity of the Y-chromosome. This type of hereditary transmission of characters has been observed also in 2 species of fish.—*H. W. Feldman.*

1772. CHEVALIER, AUGUSTE. L'origine du maïs d'après G. N. Collins. [Rev. of: COLLINS G. N. Origin of maize. *Amer. Anthropol.* 23: 503-506. 1921.] *Rev. Bot. Appl.* 2: 652-658. 1922.

1773. CHURCHILL, E. P., JR. The effects of so-called conjugation in shelled Rhizopods. *Amer. Nat.* 56: 466-470. 1922.—Individuals of *Diffugia corona* often pair off and attach themselves by their oral surfaces, suggesting a true conjugation. This attachment can often be brought about by subjecting 2 animals to distilled water for a few hours. In studying the effect of this process on inheritance, the author isolated, in each case, 2 specimens differing markedly in spine number or shell size. Each individual was allowed to divide and the daughter animals occupying the original shells were induced to undergo attachment by treatment with distilled water, which the other daughter animals were allowed to start asexual lines. In this way 2 lines were obtained from each of the original animals, 1 which had undergone apparent conjugation and 1 which had reproduced asexually. A comparison of these lines indicates that the progeny from one "exconjugant" was not influenced by the genetical constitution of the other "conjugant" or that there was no intermingling of hereditary characters. This in turn indicates that the process of attachment observed in *Diffugia* and other shelled rhizopods is not a true conjugation and that there is no interchange of nuclear material. At the present time the author has not been able to make a cytological study of the behavior of the nuclei during the process of attachment.—*W. H. Taliaferro.*

1774. CLAUSEN, R. E., AND J. L. COLLINS. The inheritance of ski wings in *Drosophila melanogaster*. *Genetics* 7: 385-426. 1922.—Ski wings, discovered by Clausen and Collins, was found by them to differ from wild-type in 2 previously unknown loci lying in the 2nd and 3rd chromosomes respectively. For the mutant genes to produce a visible variation in the wing those of both the 2nd and 3rd chromosomes must be present together,—the former Si_{II} either heterozygously or homozygously (being dominant), and the latter, si_{III} , homozygously (being recessive). Homozygous Si_{II} is not lethal, and tends to be more extreme than heterozygous. On account of these conditions, various unusual genetic ratios of ski to non-ski flies were obtained in crosses, but the genetic composition of flies with respect to ski genes can always be controlled, even where effects of the latter are invisible, by utilizing their linkage relations with other ("identifying") genes. Such methods were used by the authors in making up stocks for back-crosses to determine the exact loci of Si_{II} and si_{III} . For both determinations 3-point back-crosses were made, all 4 possible "complementary" arrangements of the 3 heterozygous pairs of genes being tested in order to reduce the error due to differential viability. Si_{II} was found to be at 30.8 (on basis of 1290 crossovers from star and 660 from

black among 4,845 flies) and si_{III} at 43.4 (740 crossovers from *dichaete* and 1605 from *spineless* among 15,621). Coincidence in former experiment was 43.8 per cent; in latter, 131.5 per cent in spite of the small distances involved. Viability of *ski* was about 90 per cent of non-*ski* in good cultures, lower in poor cultures; *ski* also tends to hatch later than normal. Under good conditions it is valuable for genetic work. In the theoretical discussion the authors point out reasons why the mutations of *Drosophila* cannot be explained away as recombinations.—*H. J. Muller*.

1775. COHEN, STUART, C. P. *Iets over selectie-pluk proeven*. [Notes on selection-pluck experiments.] *De Thee* 1: 101-106. 1920.—Eleven hundred plants have been included in an individual-yield study in a search for desirable parent plants. Extreme variability in yield was found, due partly to age differences. This variability was considerably reduced by separating the trees examined into 10 crown classes. Even within the same crown class there is much difference between different trees, and the differences are not entirely constant, a tree giving a good yield at one picking perhaps yielding poorly at a subsequent picking. This last fact may permit of analysis. For example, a low temporary yield for a plant may be correlated with a *Helopeltis* attack, indicating its susceptibility to the insect.—*Carl Hartley*.

1776. COHEN, STUART, C. P. *Productievermeerdering door selectie*. [Yield increase by selection.] *De Thee* 1: 68-71. 1920.—The author recommends preliminary selection of individual tea plants by 3 criteria: weight per tip, length of time elapsing before the shoot is ready for the next picking, and the number of side shoots arising from the cut ends. This has the advantage over selection based on determination of individual yields in that it requires less labor and permits the discovery of plants which are especially high in one or another of the above 3 characters and therefore valuable for crossing purposes. Weakness in one of the other characters might, however, keep the yield down and prevent detection by the total-yield method.—*Carl Hartley*.

1777. COOK, O. F. *One-variety cotton communities*. U. S. Dept. Agric. Bull. 1111. 50 p. 1922.—The author discusses importance of pure seed in cotton production, disadvantages of growing several varieties in the same community and difficulties under prevailing system of obtaining commercial quantities of pure planting seed of superior varieties, and of initiating production of such varieties. Present multiplicity of varieties or varietal names is shown to be an unfavorable factor in cotton production. Solution of the problem is believed to lie in organizing communities to grow only 1 variety. The advantages of such organization in facilitating field classing and orderly marketing of product and proper agricultural diversification are pointed out. Descriptions are given of communities already organized on 1 variety basis for the production of Pima, Meade, Durango, Acala, and Lone Star cottons.—*T. H. Kearney*.

1778. COURRIER, R. *Sur l'indépendance de la glande séminale et des caractères sexuels secondaires chez les poissons. Etude expérimentale*. [Independence of the seminal gland and secondary sex-characters in fishes. Experimental studies.] *Compt. Rend. Acad. Sci. Paris* 174: 70-72. 1922.—In *Gasterosteus aculeatus*, the male at breeding season possesses 2 secondary sex-characters: (1) rose-colored pigmentation of belly, and (2) a musky secretion of the renal cells. Testes of males caught in winter and kept at elevated temperatures develop exactly as those of males caught in summer, the breeding season. This induced development of testis is not accompanied by development of secondary sex-characters. Particularly is this true of the secretion of the renal cells, although the animal is kept at the same conditions of temperature and nutrition as in summer. A faint coloration of the males under the experimental conditions occasionally appears. The author concludes that the 2 secondary sex-characters of stickleback react differentially to the sexual hormone of the interstitial cells; there appears to be a quantitative difference. The amount of hormone required to influence the chromatophores is less than the amount necessary to cause the characteristic reaction of the nephrocytes.—*S. W. Geiser*.

1779. DUNN, L. C. A gene for the extension of black pigment in domestic fowls. Amer. Nat. 56: 464-466. 1922.—Black fowls differ by 1 dominant autosomal gene from Columbian and buff varieties in which black pigment is restricted to hackle, flight, and tail feathers. Black is incompletely epistatic over silver; black fowls therefore contain buff, the recessive allelomorph of this sex-linked gene. Evidence is derived from reciprocal crosses between Black Orpington and Columbian pattern (Light Brahma) fowls, and from backcrosses of F_1 with non-black individuals.—*H. W. Feldman*.

1780. DUNN, L. C. Inheritance of plumage color in crosses of buff and Columbian fowls. Amer. Nat. 56: 242-255. 1922.—The results of crossing Buff (Orpington and Ply mouth Rock) and Columbian (Light Brahma) varieties of fowls are reported. The 2 varieties were found to differ (1) in a dominant sex-linked gene (*S*, silver) which inhibits development of buff in the plumage of Columbian varieties; (2) by multiple genes governing the degree to which black is produced in hackle, wing, and tail feathers. It is suggested that Columbian and Buff varieties originally diverged through the occurrence of a gene mutation affecting the inhibition of buff, and through the subsequent accumulation by selection of factors for much black pigment in wing, tail, and hackle feathers of Columbian varieties; and by a reverse selection in Buff varieties.—*L. C. Dunn*

1781. DÜRKEN, BERNHARD. Versuche über die Erbllichkeit des infarbigem Lichte erworbenen Farbenkleides der Puppen von *Pieris brassicae*. [Studies on the inheritance of the coloration induced in the pupae of *Pieris brassicae* by colored light.] Nachrichten K. Ges. Wiss. Göttingen 1919: 428-434. 1919.—Of chrysalids from larvae of *P. brassicae* raised and allowed to pupate in orange light 77.8 per cent were green, 22.2 per cent being white and black. Only 7 per cent of those in control cultures raised in normal non-colored environment were green, 93 per cent being white and black. Orange light prevents the development of black and white pigments and allows the green blood and tissues to shine through the integument.—When merely the pupa during the process of pupation was exposed to orange light, 62.8 per cent of green pupae were obtained. Butterflies from these green pupae produced 98.2 per cent of green pupae when the larvae pupated in orange light, and 45.9 per cent green pupae when the larvae pupated in diffuse white light with gray background.—Pupal color depends in large measure upon that of the parents. Particularly, the green condition acquired by exposing the pupa to orange light was transmitted to unexposed progeny. Moreover, if the application of orange light is repeated by exposing the offspring, the effect is cumulative. Practically all the offspring of the next generation assume the acquired condition. Since the pupa at the time of the application of orange light is not yet sexually mature, the germ cells probably do not react immediately to orange light but acquire later the condition previously produced by the modifying agent in the medium that surrounds them.—Tentative conclusion: Pupation in orange light causes a specific chemical condition of the body saps. The germ cells acquire this condition. The transmission of this acquired character is not by the modification of special nuclear vehicles of heredity but by a change in the chemical plasmatic constitution of the gametes. The inheritance is not karyogenetic but plasmogenetic.—*John H. Gerould*.

1782. ENGLEADOW, F. L., AND J. P. SHELTON. An investigation upon certain metrical attributes of wheat plants. Jour. Agric. Sci. 12: 197-205. 1922.—One-year's results (1920) with pure lines of Polish and Kubanka wheats are reported from an investigation with the primary object of determining whether the ratio of length of glume to length of rachis would provide a "compensated" observation as a means of removing the masking effects of fluctuation due to unattainable uniform conditions of growth. A high correlation of glume-length and rachis-length was found in both wheats but the ratio of these quantities had as great a coefficient of variation as the absolute glume-length, and, therefore, the ratio possesses no special value in investigation. Correlations of about $+ .5$ were found among the tillers of any 1 plant for glume-length and rachis-length. With similar metrical observations it is concluded that observations should be confined to the main stalk of every plant and that it is desirable to limit the experimental population to plants with the same number of tillers. Weight of

mother seed was not correlated with degree of growth of plant as judged by lengths of glume and rachis.—*R. D. Lewis.*

1783. EYSTER, WILLIAM H. Scarred endosperm and size inheritance in kernels of maize. Missouri Agric. Exp. Sta. Res. Bull. 52. 10 p., 2 pl. 1922.—The character "scarred endosperm" (*Scsc*) appears as an irregular crater-like cavity in the endosperm on the abgerminal side near the crown of the kernel. The collapse of the pericarp over the cavity usually causes the appearance of "rough" indentation. Scarred kernels are smaller than normal kernels of the same ear, particularly in thickness, and are lighter in weight.—Scarred is inherited as a simple Mendelian recessive. The author points out that this, like various other characters in maize and other plants, is a quantitative character determined by a single factor difference.—*L. J. Stadler.*

1784. FABRICIUS, L. [Rev. of: (1) FRUWIRTH, C., UND TH. RÖMER. Einführung in die landwirtschaftliche Pflanzenzüchtung. (Introduction to agricultural plant breeding.) 160 p., 27 fig. Berlin, 1921. (2) BAUR, ERWIN. Die wissenschaftlichen Grundlagen der Pflanzenzüchtung. (Scientific basis of plant breeding.) 115 p., 11 fig. Berlin, 1921 (see Bot. Absts. 12, Entry 1034).] Forstwiss., Centralbl. 44: 119-121. 1922.—These books are brief and written in simple comprehensible language. The 1st emphasizes the practice, the 2nd the theory of plant breeding. They devote practically no space to breeding of forest tree species, for the good reason that foresters have done nothing beyond a little work on selection of seeds for planting. The difficulty of the longer generations in trees is pointed out. [See also Bot. Absts. 12, Entry 1831].—*W. N. Sparhawk.*

1785. FEDERLEY, HARRY. Ueber einen Fall von Criss-cross-Vererbung bei einer Artkreuzung. [A case of criss-cross inheritance in a species cross.] Hereditas 3: 125-146. 1922.—The dark, blue-black pigmentation and coarsely mottled pattern of the caterpillar of *Pygaera anachoreta* are dominant to the lighter color and finely mottled pattern of *P. curtula*. Save in a few details the 2 patterns are inherited as sex-linked units. F_1 caterpillars from *P. curtula* ♀ × *P. anachoreta* ♂ are alike in both sexes and resemble *P. anachoreta*, but F_1 from the reciprocal cross, *P. anachoreta* ♀ × *P. curtula* ♂ shows criss-cross inheritance. All the ♂♂ are dark and coarsely mottled like the mother; all the ♀♀ are light and finely mottled like the father. The F_1 species-hybrid ♀ is apparently sterile and matures so much later than the ♂ (the following season) that it has been impossible to obtain the F_2 , but *P. anachoreta* ♀ × the (*anachoreta*-like) F_1 ♂ has given numerous cultures and individuals of both sexes, all *anachoreta*-like save in minor details. *P. curtula* ♀ × the F_1 (*anachoreta*-like) ♂ has produced a few (*anachoreta*-like) ♂♂ only.—The chromosomes of the F_1 hybrid ♂ in gametogenesis do not conjugate, but divide equationally in maturation, each spermatozoon receiving a complete set of chromosomes of each species. Heterochromosomes are not distinguishable in either *P. anachoreta* (with its 30 chromosomes) nor in *P. curtula* (with 29), but assuming that $XX = ♂$, $XY = ♀$, and that the coloration of the 2 species, *a* and *e*, is borne by Xa and Xc , respectively, then the F_1 hybrid from *P. anachoreta* ♀ × *P. curtula* ♂, back-crossed with the ♀ of either species (XaY or XcY) would give only *P. anachoreta*, for the progeny receive in each case from the hybrid ♂ both Xa and Xc . Thus ♂♂ from each back-cross are "triploid and presumably contain also three X-chromosomes." "The females are also triploid, but these contain the allosomes XXY ." Intersexual individuals, poorly developed as a rule, are found among them. The Y-chromosome contains "factors which influence the differentiation of sex and develop specific female characteristics in spite of the presence of the two X-chromosomes which ought to ♂-mark the individuals." The sex-linked pigmentation factors, however, are not carried by the Y.—An anomalous *anachoreta*-like ♀ larva was found in a large brood from *P. anachoreta* ♀ × *P. curtula* ♂. Appearing simultaneously with the males it was mated with a brother, but no eggs developed. This individual is believed to have "arisen through non-disjunction in an egg of the heterogametic mother," ($XaXcY$). "It must have received the Y-chromosome from the mother; its development into a female would otherwise have been impossible. The Xa chromosome must also have been obtained

from the *anach.* mother; the *anach.* resemblance would not otherwise have been obtained."—*John H. Gerould.*

1786. GANTE, TH. Über eine Besonderheit der Begrannung bei Fatuoid-Heterozygoten. [On a peculiarity of bearding on fatua-like heterozygotes.] *Hereditas* 2: 410–415. 1922.—Nilsson-Ehle previously described a homozygous fatuoid mutation which differs from *Avena sativa* in that all flowering glumes are awned, rachis and kernel base are pubescent, and a basal ring is present. He found another mutation, a heterozygous fatuoid mutant, which segregates out in 1:2:1 ratio. This heterozygote is stronger awned than the normal, the awn is more bent, the base of lower kernel and rachis are more pubescent, and it has no basal ring. The author found that these heterozygotes have either all glumes awned or, where there are 3, the 2 lower ones. He states that this 2-awnedness does not depend on bud mutation, that no intermediate forms appear, and that it relates more to the modification of a varietal characteristic.—*L. J. Henning.*

1787. GOLDSCHMIDT, R., UND E. FISCHER. *Argynnis paphia-valesina*, ein Fall geschlechtskontrollierter Vererbung bei Schmetterlingen. [*Argynnis paphia-valesina*, a case of sex-controlled heredity in Lepidoptera.] *Genetica* 4: 247–278. 1922.—A "melanic" female variety, *valesina*, of the silver spot, *A. paphia*, occurs with the typical yellowish-brown female over the greater part of the palaearctic realm. The former alone occurs in the mountains of North China. Eastward, the proportion of dark females to brown diminishes. *Valesina* is rarely found with the type female in the low plains of Central Europe, and is not represented in North Africa, nor in Japan.—Fischer bred at Zürich (1915–1919) 4 lines of stock from a single Königsberg *valesina* ♀, the hibernating caterpillars of which matured in 1915 as 94 ♂♂, 35 ♀♀ *paphia*, 25 ♀♀ *valesina*. Methods are given for management of egg-laying (in large glass cylinders lined with netting) care of young caterpillars during their long fast and hibernation (from July, or August, to April), their feeding on leaves of the violet, and for the pairing of the butterflies.—Goldschmidt explains var. *valesina* as due to a single dominant non-sex-linked factor, *V*, the ♀ *Valesina* being *VV* or *Vv*, the ♀ *paphia* always *vv*. The ♂ is uniformly *paphia*-like, but may carry latent the *valesina* factor, being *VV*, *Vv* or *vv*. In regions in which *valesina* does not occur, the male is *vv*.—Nine combinations of the 3 genotypes of the male with the 3 of the female are possible. Six of them were represented in Fisher's cultures:

1. Male *vv* × female *vv* → 16 families, females all *paphia* (except 1 waif).
2. Male *Vv* × female *vv* → 5 families, females 104 *vv* + 68 *Vv*.
3. Male *VV* × female *vv* → 3 families, females 168 *Vv* (+ 1 stray *vv*).
4. Male *vv* × female *Vv* → 11 families, females 357 *vv* + 353 *Vv*.
5. Male *Vv* × female *Vv* → 13 families, females 143 *vv* + 367 (*Vv* + *VV*).
6. Male *VV* × female *Vv* → 1 family, females 21 (*Vv* + *VV*) all *valesina*.

Thus in only 1 case has a *valesina* ♀ produced only *valesina* offspring, and homozygous *VV* females do not appear as the mothers of broods. Is the *VV* combination lethal? 2.57:1 is the ratio derived from the *Vv* × *Vv* mating, indicating a shortage of *VV* ♀♀. Two of the largest families contain, respectively, 60 *Vv* + 30 *vv* and 61 *Vv* + 27 *vv* females, instead of 3 *valesina*: 1 *paphia*. *VV* females can be demonstrated as mothers in 2 mixed broods, assuming that the (wild) fathers must have been *vv*. Hence it is impossible that *VV* is lethal, even in the female, but a numerical summary shows that in this sex it is "semilethal," or relatively susceptible, and that the ♀ *Vv* is not quite so viable as the ♀ *vv*.—The peculiarity of sex-controlled heredity is that ordinary Mendelian segregation of one or more factors is phenotypically visible only in 1 sex. The explanation of this phenomenon must be physiological. It may be assumed either (1) that, in view of sex differences known to occur in the blood of Lepidoptera, the chemical constituents necessary for the realization of certain genes may be lacking in the male, through the genes are present, or (2) at the moment in the development of wing pigment when a sex-controlled factor is about to play its part, differentiation in the male has already reached a point at which no further change is possible, whereas differentiation in the female is not yet so far advanced and the organism therefore is susceptible to the action of the genetic factor. The latter explanation is regarded as the more satisfactory.—*John H. Gerould.*

1788. GOODSPEED, THOMAS HARPER, AND ROY ELWOOD CLAUSEN. **Interspecific hybridization in Nicotianas. I. On the results of backcrossing the F_1 sylvestris-Tabacum hybrids to sylvestris.** Univ. California Publ. Bot. 11: 1-30. 1922.—The authors summarize their "results" as follows: (1) Three *sylvestris* derivative lines, originating from backcrosses of F_1 *sylvestris-purpurea* hybrids to *sylvestris*, have been studied and shown to become identical with normal *sylvestris*. (2) One *sylvestris* derivative line from the *sylvestris-macrophylla* series has also been demonstrated to be identical with normal *sylvestris*. (3) A cross of a *sylvestris* derivative from the *sylvestris-purpurea* series with *purpurea* resulted in a dimorphic F_1 , which may be interpreted as evidence of the existence of a section of *Tabacum* elements in the *sylvestris* derivative. Since the *sylvestris* derivative was heterozygous for this section of *Tabacum* elements, this provides presumptive evidence of eventual purification of *sylvestris* derivatives by a process of zygotic elimination.—W. A. Setchell.

1789. GUTHRIE, F. B. **William J. Farrer, and the results of his work.** Dept. Agric. New South Wales Sci. Bull. 22. 26 p., 1 fig. 1922.—A biographical sketch is given of W. J. Farrer and a summary of his work. This pioneer wheat breeder graduated from Cambridge as senior wrangler in the mathematical tripos. He was strikingly successful in the production of wheat varieties combining the 3 characters high milling quality, resistance to stem rust, and drought resistance. Among the most important Farrer wheats produced have been Bobs, Federation, Comeback, Cedar, and Florence. Farrer's ideas in genetics are set forth and a Farrer bibliography is appended.—L. R. Waldron.

1790. GUYÉNOT, E., et K. PONSE. **L'organe de Bidder et les caractères sexuels secondaires du crapaud (*Bufo vulgaris* Laur.).** [The organ of Bidder and the secondary sexual characters of the toad (*Bufo vulgaris*).] Compt. Rend. Soc. Biol. 86: 751-752. 1922.—Harms had indicated that the secondary sex characters, such as sexual attraction, clasping reflex, etc., are dependent on the organ of Bidder. This statement is contradicted experimentally by removing the organ of Bidder from 10 toads and noting no diminution of secondary sex characters in these toads the following year. Another group of 26 had the testes removed and they showed none of the secondary sex characters. A 3rd group had the organ of Bidder and the testes extirpated and these toads showed complete absence of the secondary sex characters the following summer. The authors conclude that the secondary sex characters are dependent on the testes and not on the organ of Bidder. Also, the organ of Bidder is a rudimentary organ, as observed by them in the precocious development of a young male toad.—Oscar W. Richards.

1791. GUYER, M. F. **Studies on cytolytins. III. Experiments with spermatotoxins.** Jour. Exp. Zool. 35: 207-223. 1 fig. 1922.—Fowls subjected to repeated injections of rabbit sperm produce a spermatotoxic serum which is very toxic to rabbit spermatozoa *in vitro*, and variably toxic to rabbit spermatozoa *in vivo*. Complete sterility and degeneration of the spermatid tubules may be the result in extreme cases of this toxic action. In less extreme cases inactivation of many spermatozoa, or reduction of their number, or complete absence of them from the semen is frequently the result of such injections into the blood stream. These spermatotoxins produced in the fowl are equally toxic *in vitro* for the spermatozoa of rabbits and guinea-pigs. The rabbit is able to produce spermatotoxins against its own spermatozoa. Thus, males frequently injected intravenously with suspensions of their own spermatozoa showed weakened sperm-cells. The author holds that "since an animal can thus on occasion build antibodies against its own tissues when these have become misplaced or altered, and since antibodies can directly or indirectly affect the germ cells, it is reasonable to suppose that such influences may be the source of certain germinal variations."—S. W. Gieser.

1792. HAECKER, VALENTIN. **Einfach-Mendelnde Merkmale.** [Simple Mendelian characters.] Genetica 4: 195-234. 1922.—This is a discussion of the nature of simple Mendelian characters in terms of their developmental characteristics and of related problems of theoretical genetics. The 1st part deals with the difference between racial and specific characters

and presents arguments for the necessity of attacking the problem both from the angle of genetic behavior and phenogenesis. Phenogenesis aims to bridge the gap between characters of an individual and its germinal elements. Its method is to trace back on ontogenetic processes to the point at which divergence occurs and to determine whether differences rest on simple or complex causation.—Simple Mendelian characters exhibit simple causation and autonomous development, but irregularity in inheritance is associated with complex causation and correlative associations in development. The author states that simple Mendelian characters exhibit a series of peculiarities; particularly, high degree of ubiquity (parallel occurrence in taxonomically related forms), simple causation and autonomous development, and also a certain degree of irreversibility as shown by the occurrence of reverse mutations. He states that simple Mendelian characters in the widest sense correspond with racial characters; he argues that the higher the degree of ubiquity of a character, the simpler causation and greater autonomy it will exhibit in development. From these considerations he argues for the superficiality of simple Mendelian characters, and cites numerous examples in support of his theses.—The 2nd part of the paper is concerned with a discussion of difficulties inherent in present conceptions of the mechanism of heredity and with possible means of effecting an improvement in these conceptions. In general he commends attempts to appeal to cytology for an elucidation of genetic behavior, but holds that present mechanistic conceptions must eventually make way for physiological ones. He describes various features of the chromosome hypothesis, particularly linkage relations and crossing-over. Cytological difficulties in accepting Morgan's scheme are considered at length; other theories of linkage and crossing-over are also discussed. He holds that any attempt to develop relations of pure and impure segregation, linkage and recombination of linked factors to cytological results must satisfy these conditions: (1) the cytological processes must ultimately be expressed in physiological terms; (2) the pluripotency of the germplasm must be considered, the phenotypes corresponding to different potencies representing the simple Mendelian mutants; and (3) the occurrence of intracellular alterations of genes, whereby one member of a pair of genes may be altered prior to segregation (leading to imperfect segregation), must be recognized. The author argues that when 2 races differing in characters of simple causation are crossed the 2 germplasms are identical save in the particular factors separating the races and therefore produce no enzymes which alter the genes, consequently perfect segregation follows; but when parental forms differ in characters of complex causation alteration activities may occur followed by imperfect segregation or complicated hereditary phenomena. When one parent contains 2 linked mutant genes, he argues that recombination may be an evidence of alteration in genes, due to the greater complexity of such conditions, whereby one member of a pair is converted into the other in a definite frequency. Finally he points out that phenogenetic investigations indicate that all transition stages occur between simple Mendelian characters and those which exhibit irregular inheritance, and that since the underlying mechanism of heredity must be the same for all characters, a further search may disclose a more general principle, of which the present hypotheses are merely special cases.—*R. E. Clausen.*

1793. HALDANE, J. B. S. Sex ratio and unisexual sterility in hybrid animals. *Jour. Genetics* 12: 101-109. 1922.—“When in the F_1 offspring of two different animal races one sex is absent, rare or sterile, that sex is the heterozygous sex.” This rule is found to apply to practically all of the cases (44 references) so far observed.—*E. C. MacDowell.*

1794. HARRINGTON, J. B. The mode of inheritance of certain characters in wheat. *Sci. Agric. [Canada]* 2: 319-324. 1922.—Working with 6 well known Canadian wheats, the segregation for seed color occurred in both 3:1 and 15:1 ratios, red being dominant to white. The variety Kitchener has 2 factors for seed color, but Hard Red Calcutta and Red Bobs have 1 or 2 in different selected lines. Several factors appear to govern seed texture, the distribution in F_2 approximating the extreme range of the parent varieties. Two factors appear to be concerned in the production of fully awned spikes. Factors present in varieties studied are designated as follows: Hard Red Calcutta, *BBTT* (fully bearded); Taylor's Wonder, *BBtt* or *bbTT* (tip-awned); and White Bobs, *bbtt* (bald). These parental combinations reappeared

in the F_2 of a cross between the first and last varieties named together with several heterozygous forms intermediate between the parent sorts. *BBTt* and *BbTT* gave long tip-awns; *Bbtt* and *bbTt*, short tip-awns; and *BbTt*, fairly short. Chaff color segregated for dark red: light red: white in 1:2:1 ratio.—*C. E. Leightly*.

1795. HARRIS, J. ARTHUR, and H. D. GOODALE. The correction between the egg production of the various periods of the year in the Rhode Island Red breed of domestic fowl. *Genetics* 7: 446-465. 7 fig. 1922.—Annual egg records of 1,658 birds made during their 1st laying year of 365 days were studied. These records were all secured from the flock at the Massachusetts Agricultural Experiment Station during 1912-1919. Calculated correlation coefficients between the production of individual months and annual records indicate that the number of eggs laid by these hens during January, December, and September bear the closest relationship to annual production. The above correlations for the Rhode Island Red breed differ from the Storrs White Leghorns, where the highest correlation was found during July, August, and September. The months of January and September, respectively, show the 2 highest correlation coefficients to the production of the other 11 months of the year. The highest positive correlation between annual egg production and the deviation of monthly records from their probable value existed for December and a negative coefficient exists for March, April, May, June, and July. Correlation determinations between the production of individual months enabled the authors to apply 2 laws previously found applicable to the White Leghorn breed. "First, the correlation between the egg production of the individual months tends to become smaller as the months considered are more widely separated in time. Second, there is a more intimate correlation between the egg production of the autumn and winter months at the beginning and end of the contest year than between the egg production of these months and the productions of the spring and summer months."—*F. A. Hays*.

1796. HARRIS, J. ARTHUR, and ALBERT GOVAERTS. Note on assortative mating in man with respect to head size and head form. *Amer. Nat.* 54: 381-383. 1922.—Because of Pearson's suggestion that correlations indicating assortative mating may be due to the fact that husbands and wives are in general drawn from the same local races, and further, because of the importance attached by anthropologists to cephalic index as a character differentiating the races of Europe, the authors thought it desirable to obtain some measure of the correlation between husband and wife with respect to cephalic index. They used as material 319 Dutch families, finding the correlation between cephalic index of husband and wife within this racial group insignificant. The correlation between length of head of husband and wife is also insignificant, while the breadths may perhaps be significantly correlated.—*Sylvia L. Parker*.

1797. HAWKES, ONERA A. MERRITT. Studies in inheritance in the hybrid *Philosamia* (*Attacus*) *ricini* (Boisd.) ♂ × *Philosamia* *cynthia* (Drury) ♀. *Jour. Genetics* 12: 111-135. 1922.—Part II. Pupal characteristics. Cocoon color of *P. ricini* is pure white; of *P. cynthia*, red brown. In F_1 between the 2 species there were only intermediates. In succeeding generations there was no complete segregation, and the effects of moisture complicated the case. Part III. Imaginal characteristics. (1) Inheritance of color. *P. cynthia* and *P. ricini* differ strikingly in the color of the middle portion of the wings due (a) to arrangement of scales, and (b) to pigmentation of the scales. In F_1 the Vandyke brown of *P. ricini* is apparently dominant to the mottled yellow of *P. cynthia*, but microscopical examination shows the dominance to be incomplete due to the presence of a few colored scales of *P. cynthia*. In F_2 there was segregation of color into 4 groups, *DK* (dark, *ricini*-like), *DKK* (very dark, a new character), *LI* (light, *cynthia*-like), and *LII* (a new pale type). *LII* bred true for 3 generations, *DKK* for 2. No sex linkage, nor correlation between scale colors and the colors of the larva, was observed. (2) Inheritance of scale shape. Scales studied were taken from a limited area just beyond the outer angle of the lunule on the anterior right wing. Matings were made at random for 5 inbred generations. The *cynthia* characteristics (wide, several long prongs) showed the greater amount of influence in F_1 . F_2 showed greater variation but no segregation into original types. Two new forms appeared in the F_3 , (a) rapidly converging sides and (b)

barrel-shape. F_4 included 3 families with considerable homogeneity. The remaining families were similar to those in earlier generations. In F_5 some individuals have characteristic scales. The recessive, narrow, 2-5 pronged ricinian scale breeds true. In F_6 a new type of scale, barrel-shaped, is "apparently stable for one generation." It is concluded that shape of scales must be due to a number of independent factors for (a) length, (b) number of prongs, (c) relative length of prong, (d) parallel or converging sides. (3) Inheritance of size. As a criterion of size the distance from base of wing to middle of the eye spot was taken, which in *P. ricini* was 49 mm. and in *P. cyntia* 59 mm. F_1 individuals had approximately the size of *P. ricini*. In the 5 succeeding generations the sexual size difference of *P. cyntia* was lost. Hybridization apparently caused a break-up of the sex complex of *P. cyntia*. No complete segregation occurred. Inbreeding was detrimental to size only to a very small extent; fertility was not impaired. (4) Sex ratio. F_1 showed an excess of females (63 ♀, 46 ♂), but all succeeding generations an excess of males. (5) Inheritance of white hairs on the abdomen of *P. ricini* vs. brown with tufts of white in *P. cyntia*. No regularity of inheritance was noticed. Every variation between *P. ricini* and *P. cyntia* was produced, but the extremes were rare.—Lloyd C. Fogg.

1798. HILSON, G. R. Uniformity of length of cotton hairs. Agric. Jour. India 16: 564-566. 1921.—Methods are discussed for rapid determination of length of fiber in cotton breeding. Close correspondence is found between results obtained by measurement of numerous individual fibers and by Balls' "maximum combed length" method.—T. H. Kearney.

1799. HORLACHER, L. J., and E. S. GOOD. Breeding experiments with Kentucky mountain ewes. Kentucky Agric. Exp. Sta. Bull. 243. 137-199, 69 fig. 1922.—An account is given of 6 years' breeding work in an attempt to improve the characteristic of the progeny and eventually build up the flock by the use of pure bred rams. The progeny of mountain ewes with Hampshire, Cheviot, Southdown, Rambouillet, and mountain rams were compared and some of these hybrids were again crossed with either a ram of the same breed or of another breed. The per cent of twin lambs produced by the above named rams respectively was 71.8, 63.9, 44.1, 37.5, and 31.5. The Rambouillet was the most satisfactory ram used for improving the mountain ewes. The grade Hampshire lambs gained more rapidly but lacked quality. The Southdown grades possessed quality but gained slowly and the ewes were too small. The Cheviot grades grew more rapidly than Southdown grades and had finer quality than Hampshire and Rambouillet grades. Use of pure bred rams increased the weight of the fleece from 5 pounds to 5.74-7.52 pounds.—W. D. Valteau.

1800. JONES, SARAH V. H. Studies on inheritance in pigeons. IV. Checks and bars and other modifications of black. Genetics 7: 466-507. 13 fig. 1922.—The "bluing" series in pigeon color is described in 6 types according to the amount of blue color in the plumages. These are classified as epistatic in hereditary behavior in the same order. The types are named (1) full black, (2) black blue-tail, (3) medium check, (4) sooty blue, (5) blue black-barred, (6) blue barless. Factor *S* effects a uniform distribution of pigment in the barbules of black feathers while *s* indicates the clumped condition in blue feathers. Black thus differs from barred in a single factor shown by breeding tests. Breeding tests between 5 pairs of heterozygous blacks gave 25 blacks and 8 checks, a typical monohybrid ratio. Eleven matings between individuals heterozygous for check gave 59 checks to 18 barred, indicating a 3 to 1 ratio. A factor *C* is postulated which is not linked to *S* but can act only in the presence of *s* to produce the checked patterns. A factor *T* hypostatic to *S* accounts for class 2, black blue-tail birds. Factor *S_o* accounts for sooty. Barless is known only to be recessive to barred *B_a*. These factors are not of a multiple allelomorphic series.—F. A. Hays.

1801. KEARNEY, THOMAS H. The uniformity of Pima cotton. U. S. Dept. Agric. Circ. 247. 6 p. 1922.—Evidence that cotton varieties do not "run out" if protected from cross-pollination and mixture of seed is afforded by the history of Pima variety of American Egyptian cotton. A method is described of maintaining a supply of good planting seed of this variety

and evidence given from roguing statistics and from results of specially planned experiments that purity of this variety has been preserved during 7 years of commercial production in Arizona.—*T. H. Kearney*.

1802. KOEHLER, OTTO. *Neuere Arbeiten über hennenfiedrige Hahne*. [New studies on hen-feathered cocks.] *Zeitschr. Indukt. Abstamm.- u. Vererb.* 29: 73-82. 1922.—This is a German review of several recent papers on hen-feathering.—*O. E. White*.

1803. KOEHLER, OTTO. [German rev. of: GEROULD, JOHN H. *Blue-green caterpillars: The origin and ecology of a mutation in hemolymph color in Colias (Eurymus) philodice*. *Jour. Exp. Zool.* 34: 385-412. 1 pl. 1921 (see *Bot. Absts.* 11, Entry 1348).] *Zeitschr. Indukt. Abstamm. u. Vererb.* 29: 141-143. 1922.

1804. KUTTNER, O. [German rev. of: BANTA, ARTHUR M. *Selection in Cladocera on the basis of a physiological character*. *Carnegie Inst. Washington Publ.* 305. 170 p. 1921.] *Zeitschr. Indukt. Abstamm.- u. Vererb.* 29: 141. 1922.

1805. LANCEFIELD, D. E. *Linkage relations of the sex-linked characters in Drosophila obscura*. *Genetics* 7: 335-384. 1922.—*D. obscura* is slightly larger and of a darker color than *D. melanogaster*. It breeds readily in the laboratory, and requires 14-20 days for a generation. Forty mutations have been produced, of which $\frac{1}{2}$ are dominant. Some are very similar to those of other species. Twenty-eight sex-linked mutations have appeared in 23 loci. The linkage groups, of which there are 5, correspond to the haploid number of chromosomes. Non-disjunction of the sex-chromosome was not observed in 309 suitable cultures. Frequent crossing-over between sex-linked characters gives the X-chromosome a total "length" of 170 units. Evidence suggests that the size differences of the X-chromosomes of *D. melanogaster* and *D. obscura* are due to the presence of a large piece of chromosome attached at what corresponds to the left end of the *D. melanogaster* X. Linkage studies indicate that similar genes do not have the same arrangement in *D. obscura*, as in *D. melanogaster*. Descriptions of sex-linked characters of *D. obscura* are presented.—*W. H. Feldman*.

1806. MATHEWS, J. WRENFORD. *Cross-breeding for wool and mutton. Results of experiments*. *Dept. Agric. New South Wales Farmers' Bull.* 132. 61 p., 24 fig., 4 charts. 1920.—The long wool breeds (Lincoln, Leicester, and Border Leicester) are more valuable for mating with the Merino than the down breeds (Southdown, Shropshire, and Dorset Horn). The Merino ewe is to be preferred to the long wool ewe because of environmental conditions. For natural increase the Leicester breed showed 6 per cent superiority to either Lincoln or Border Leicester. The Border Leicester surpassed Lincoln and Leicester as parent in value of lamb carcass for export, in body weight, fleece weight, fleece value, and generally in mutton value.—*L. R. Waldron*.

1807. MENDIOLA, N. B., and J. R. MAGSINO. *Study of bud variation in Codiaeum variegatum*. *Philippine Agric.* 11: 19-22. 2 pl. 1922.—Eighteen varieties of *C. variegatum* (L.) Blume (Croton) were studied and each was subjected to several different treatments of soil and exposure. The author reports that, after 1½ years, a case of terminal and one of lateral bud mutation involving the same shape of leaf, and a change from broad to slender shape, were found in one variety; in this variety, also, a bud mutation involving a change in leaf coloration was found. These variations grew true to type when cuttings were made.—*Sam F. Trelease*.

1808. NACHTSHEIM, H. [German rev. of: SCHMALTZ, R. *Das Geschlechtsleben der Haussäugetiere*. (The reproduction of domestic animals.) 3rd rev. ed., 529 p., 67 fig. R. Schoetz: Berlin, 1921.] *Zeitschr. Indukt. Abstamm.-u. Vererb.* 29: 143. 1922.—Nachtsheim hails this revised edition as of great value to geneticists and others who wish an exhaustive account of the physiology of reproduction of domestic animals. He regrets that in the discussion of the numerous theories of sex-determination no mention is made of the relations of chromosomes to sex.—*Sewall Wright*.

1809. NILSSON-EHLE, H. **Über freie Kombination und Koppelung verschiedener Chlorophyllerbinheiten bei Gerste.** [Coupling and independent combination of distinct chlorophyll factors in barley.] *Hereditas* 3: 191-199. 1922.—Six factors for chlorophyll development in barley were tested for their genetic relationship. These included 3 factors for white seedlings, 2 for yellow, and 1 for a chlorina type. Only 1 case of linkage was found, that between 1 of the white factors and the chlorina. Deviation from an F_2 ratio of 9 green: 3 chlorina: 4 white seemed to indicate a correlation which was substantiated in the F_3 progenies from green F_2 plants. Instead of a 1:2:2:4 proportion of different progenies, a 0:9:12:126 ratio was found. On the basis of 5 per cent "Koppelung," or crossing-over, the data are in better accord. Factor interrelations between the other chlorophyll factors are discussed.—*E. W. Lindstrom.*

1810. ORTON, J. H. **The phenomena and conditions of sex-change in the oyster (*O. edulis*) and *Crepidula*.** *Nature* 110: 212-214. 1922.—Of 1 year old oysters, the smaller ones were males and the larger ones were either females or had spawned as females or were changing or had changed into males. The author concludes that all oysters are born males, but may change into females at the age of 1 year. Changes noted were actually observed to occur within 1 year in 1 particular individual. A parallel rapidity in sex-change was observed in *Crepidula*. Probable causes of sex-change are discussed, but it is concluded that the information is insufficient for their determination. The view is favored that the factor for sex-causation is within control of the individual and not in external conditions. Observations are recounted which show that male *Crepidulae* favorably situated with respect to females may function as males for long periods, but when isolated rapidly change to females.—*R. E. Clausen*

1811. PATEL, M. L. **Studies in Gujarat cottons. Part I.** Mem. Dept. Agric. India Bot. Ser. 11: 75-127. 8 pl., 7 fig. 1921.—Descriptions are given of varieties of *Gossypium herbaceum* grown in Gujarat, India, and of selected strains of the Goghari variety. Heritable characters are enumerated and correlation and variation discussed. The author's conception of the ideal type of *herbaceum* cotton is presented.—*T. H. Kearney.*

1812. PEARL, RAYMOND, AND SYLVIA L. PARKER. **Experimental studies on the duration of life. IV. Data on the influence of density of population on duration of life in *Drosophila*.** *Amer. Nat.* 56: 312-321. 1922.—The authors find a significant correlation between the length of life of *Drosophila* and the number kept in a bottle. As to the form of the regression line, which appears to be significantly askew, they reach the provisional conclusion that "(a) the lowest density is not the optimum; (b) the mean, duration of life tends to increase with increasing density up to a certain point which is optimum; (c) after the optimum region has been reached, increasing density is associated with diminished duration of life, which presently falls below the lowest figure found with densities below the optimum."—*Sewall Wright.*

1813. PEARL, RAYMOND, AND SYLVIA L. PARKER. **Experimental studies on the duration of life. V. On the influence of certain environmental factors on duration of life in *Drosophila*.** *Amer. Nat.* 56: 385-405. 1922.—The authors find that the mean duration of life for *Drosophila* of wild type is about 10 per cent greater in bottles which allow free ventilation in the mouth than in bottles with cotton plug stoppers. No effect of ventilation was found in a relatively short-lived stock with vestigial wings and other recessive characters. The feeding of embryonic juice, either from the chick or from the larvae of *Drosophila*, was without effect on longevity.—*Sewall Wright.*

1814. PEARL, RAYMOND, AND SYLVIA L. PARKER. **On the influence of density of population upon the rate of reproduction in *Drosophila*.** *Proc. Nation. Acad. Sci. [U.S.A.]* 8: 212-219. 1 fig. 1922.—Matings were made (in standard half-pint bottles containing constant volume of food) with different numbers of parent flies varying from 1 to 50 pairs per bottle. The progeny from these matings were counted and the rate of reproduction—per female per day—obtained for each density. The rates were found to decrease very regularly as the density of

the parental population increased. A graph is given showing the goodness of fit of the curve, $\log y = a - bx - c \log x$, fitted by least squares to the series of points. The relation between this curve and Farr's Law relating death rate to density of population is discussed.—*Sylvia L. Parker.*

1815. PHILLIPPS, W. J. **Hybridism of *Salmo irideus* and *Salmo fario* in Australasia.** New Zealand Jour. Sci. and Technol. 5: 98-100. 1922.—This is a discussion of all work on trout hybridization in Australasia and a tabulation of results in detail obtained from crossing brown and rainbow trout both ways. Rainbow ♂ × brown ♀ may under certain conditions cross, while the reverse cross is less likely to materialize. Hybrids as compared with parents have minimum vitality and except in rare cases would not successfully compete with parents. They are often abnormal and frequently die a few days after the yolk-sac is absorbed. In rare instances, hybrids develop to sexual maturity, but whether progeny of F_1 hybrids could continue the race is unknown.—*Orland E. White.*

1816. PLATH, O. E. **Notes on the hybrids between the canary and two American finches.** Amer. Nat. 56: 322-329. 1922.—The following crosses are reported: yellow canary × California linnet, yellow canary × willow goldfinch, and willow goldfinch × Arkansas goldfinch. Results indicate that dark color is dominant to yellow. Earlier observations by others that mottling in such hybrids is due to a gene carried only by canaries was not confirmed.—*F. A. Hays.*

1817. RUEDEMANN, RUDOLF. **Additional studies in arrested evolution.** Proc. Nation. Acad. Sci. [U.S.A.] 8: 54-55. 1922.—A brief statement is presented of an investigation of the possible influence, recorded in the fossils, of the different modes of propagation upon the persistence of types.—*R. Ruedemann.*

1818. RUEDEMANN, RUDOLF. **Further notes on the paleontology of arrested evolution.** Amer. Nat. 56: 256-272. 1922.—In continuation of his previous studies of the causes of persistence in animals, the writer had investigated the possible influence of the different modes of propagation upon the persistence of types and had found that all the lower modes of propagation, viz., propagation by simple division, by budding, by hermaphroditism, and by parthenogenesis, are distinctly favorable to persistence, mainly through diminution in the frequency and range of variability as far as it is induced by fertilization. A clue to the mechanics of the processes involved in persistence is believed to be found in the views recently advanced by Dürken and Salfeld on the methods of inheritance and production of new characters by means of the genes or character-determiners of the heredity-chromatin [see Bot. Absts. 11, Entry 2431]. These authors hold that external influences act first upon the cytoplasm, which in part directly influences the heredity-chromatin and in part is changed by long-continued strain, by way of inceptive genes (plasmogenes), into true genes. The conditions which produce persistent types are not able to stimulate the cytoplasm sufficiently to lead to the formation of new genes.—*R. Ruedemann.*

1819. SEREBROVSKY, A. S. **Crossing-over involving three sex-linked genes in chickens.** Amer. Nat. 56: 571-572. 1922.—The genes suke (slow feathering), trage (barring), and tuge (silver) were studied. All 3 are present in Barred Plymouth Rocks, whereas the Russian Orloff chickens have none of them. All are sex-linked. A cross gave in F_1 all Barred Rock type of males slow feathering and all black females that developed feathers rapidly. Cross-overs occurred in these F_1 males so that in F_2 the Plymouth Rock color was combined with quick feathering and black color with slow feathering. One suke-tuge-atrage chick appeared, being slow-feathering and silvery but non-barred.—*F. A. Hays.*

1820. SHAMEL, A. D. **Recent bud-selection work in citrus and other industries.** California Citrograph 7: 358, 370-371, 386. 3 fig. 1922.—Some bud variations are inherited, while others are transitory effects of the environment. In various cases reviewed (apple, potato,

sugarcane, citrus), superior individuals within a clonal variety have given superior progeny. The author's bud-selection work aims to (1) secure improved varieties; (2) isolate improved strains of established varieties; (3) improve the average performance of valuable strains. In sugarcane, superior "stools" (plants) are selected and propagated. "In progenies grown from such selected stools less than 1 in 100 have proved to be inherently stable." About half of the world's sugarcane sugar is produced by "varieties which originated as bud mutations." Two lemon orchards propagated from high-yielding trees are mentioned; there are no control trees, but the orchards are remarkable for their uniformity and for their early and high production. In comparative tests, "evidence has been secured that the superior and inferior strains of our citrus varieties can be isolated by bud selection. Furthermore, the progenies of the highest-yielding parent trees have thus far given us the highest and best yields, while the progenies of the low-yielding parent trees of these same strains have given us the lowest and most undesirable yields."—Howard B. Frost.

1821. SINNOTT, EDMUND W. **Inheritance of fruit shape in Cucurbita pepo.** Bot. Gaz. 74: 95-103. Fig. 1-3. 1922.—Starting with commercial varieties the author was able to isolate through inbreeding a number of contrasting pure lines. The tendency toward sterility in most cases was found to disappear by the 4th generation. The cross of a certain spherical type ("sphere") with 3 varieties of the flat fruit type ("disc") indicated definite dominance of the latter with but 1 factor functioning. In 2 of the crosses the author obtained spheres in the F_2 which were decidedly flatter than the parent sphere type and the discs also were decidedly deeper than the parent disc type. This condition of things, it is pointed out, may readily be explained "by assuming that there is a second dominant flattening factor, considerably weaker in its effect than the major one [mentioned above] and segregating independently of it." Since the squashes which are longest are also those which are narrowest (the sphere type) and those which are thinnest are also those which are widest (the disc type) it is held "that shape determining factors actually exist, and that the facts here set forth are not due merely to the segregation of size factors."—B. W. Wells.

1822. SINNOTT, EDMUND W., AND ALBERT F. BLAKESLEE. **Structural changes associated with factor mutations and with chromosome mutations in Datura.** Proc. Nation. Acad. Sci. [U. S. A.] 8: 17-19. 1922.—Of the 3 gene mutants in *Datura*, the white-flowered form showed no structural differences; the smooth-capsuled form differed from the normal in having sharper angles, shorter internodes, thicker stems, and greater difference between the 2 branches at a fork; while the few-noded form had shorter main stem, shorter internodes, thinner stems, and greater difference between the 2 branches at a fork. Of the 12 forms with an extra chromosome each, Reduced had a shorter main stem, sharper angles, and thinner stems; Cocklebur had wider angles, thinner stems, and shorter internodes; Globe showed shorter internodes, thicker stems and more difference between the 2 branches at a fork; while Buckling had wider angles than the normal. Differences in the wood fibers, the vessels, and the sclerenchyma were also noted. The tetraploid plants also showed definite external and internal differences from the normals.—John Belling.

1823. SPINKS, G. T. **Fruit breeding investigation.** Univ. Bristol Ann. Rept. Agric. and Hort. Res. Sta. 1920: 61-65. 1920.—Notes are presented on the progeny of crosses between varieties of apples, pears, plums, cherries, currants, gooseberries, raspberries, strawberries, and tomatoes.—W. H. Chandler.

1824. STEIN, EMMY. **Über den Einfluss von Radiumbestrahlung auf Antirrhinum.** [Effect of radium-rays on Antirrhinum.] Zeitschr. Indukt. Abstamm.- u. Vererb. 39: 1-15. 1922.—The growing point of shoots of *Antirrhinum*, variety "Delila" from Baur's cultures, were exposed for varying lengths of time to a radium preparation consisting of 30.2 mgm. radium-barium-sulphate enclosed in a glass tube imbedded in a platinum capsule. Of the 3 types of rays emanating from this preparation, only the β and γ were active, the latter being the most effective. Exposures were made in a dark room. Exposures of 5-10 minutes had no percep-

tible influence. Exposures of 20-160 minutes checked growth temporarily and caused floral abnormalities of several types; later the plants resumed normal behavior. Exposures on a 2nd series varying from 2 to 72 hours produced another type of abnormal behavior. In all the experiments of this type abnormal behavior was temporary and results were negative as far as producing mutants is concerned.—The author also exposed seed of *Antirrhinum* from Baur's cultures; the technique is given in detail. All seed exposed 45 minutes germinated. Longer periods of exposure resulted in decreased percentage of germination in proportion to length of exposure. Seed exposed 1.5 hours produced seedlings with small, white, wrinkled cotyledons. Still longer exposures gave plants with undeveloped cotyledons and a high mortality. In other cases the vegetative point failed to develop. In still others the flowering period was greatly retarded. A large number of plants from exposed seed showed only cotyledon injury and 10 of these at flowering time were selfed and "bagged" and exposed to radium rays, resulting often in sterility. Some of the aberrant forms ("radium-plants") produced by the exposed seed are regarded as true mutants, as no such plants ever arose among the controls. These forms, though largely sterile, in a few cases gave rise to progeny which resembled them, and in one case this resemblance was repeated to the 2nd generation. When propagated by cuttings these "radium-plants" preserved their characters faithfully, though single branches often reverted to normal except for their sterility. Most important aberrant types were: (1) forms with small, "horn tipped" leaves, luxurious growth, pale flowers; (2) forms with small leaves and elongated flowers; (3) forms defective in form and color of leaves and flowers, flowers split with parts undeveloped or grotesque in shape; (4) dwarf forms (6-8 cm.), flowerless, small leaves, and shortened internodes. Flowerless dwarf form of this type was also secured from pollination of normal with pollen that had been exposed.—*C. S. Gager.*

1825. TANAKA, TYOZABURO. A new feature of bud variation in Citrus. U. S. Dept. Agric. Dept. Circ. 206. 8 p. 1922.—The Wase variety of Satsuma orange (*Citrus nobilis* Lour. var. *unshiu* Swingle) is probably the result of bud variation, some explanations of which are as follows: (1) bud variation may be the same as germinal mutation; (2) somatic segmentation of a Mendelian recessive; (3) periclinal chimeras. References numbering 23 are appended.—*L. R. Hesler.*

1826. TANAKA, Y. Sex-linkage in the silkworm. Jour. Genetics 12: 163-178. 1 pl. 1922.—The author describes a sex-linked recessive, translucent skin in the caterpillar. The female is heterozygous for sex as in other Lepidoptera. Three exceptional males, perhaps due to non-disjunction, were observed. He states that there are also at least 7 non-sex-linked genes, all recessive, that cause various degrees of translucence in caterpillars. Crosses are reported of sex-linked to non-sex-linked translucents, with complex F_2 ratios, that agree sufficiently well with the expectations.—*A. H. Sturtevant.*

1827. TOENIENSEN, E. Ueber die Entstehung erblicher Eigenschaften durch cytoplasmatische Induktion. [On the origin of hereditary characters through cytoplasmic induction.] Zeitschr. Indukt. Abstamm.- u. Vererb. 29: 16-25. 1922.—Cytoplasmic induction is the transmission to, or induction in, the germ plasm of changes produced in the cytoplasm by some outer stimulus. *Bacterium pneumoniae* under strong influence of its own metabolic products is made to produce 3 mutants. Mutant III has practically no virulence. Virulence is restored to half its original value by 80 mouse passages. Upon further cultivation on agar these mutants with restored virulence lose some, but not all, of it. Thus it appears that during the mouse passages virulence was being gradually restored, but more rapidly to the cytoplasm than to the germ plasm. The amount of regression on agar represents the cytoplasmic modification which had not yet been impressed on the germ plasm. Therefore the character is first impressed on the cytoplasm which then passes it on to the germ plasm.—*II. M. Smith.*

1828. VENKATRAMAN, T. S. A simple pollinating apparatus. Agric. Jour. India 16: 203-206. 1 fig. 1921.—A method is described and figured of pollinating sugar-cane by collecting pollen in a gelatin capsule, which is inserted in the free end of the rubber tube of a blowing

bulb. The capsule is then punctured lengthwise with a needle and pressure on the bulb releases a spray of pollen. The author mentions a method of testing viability of sugar-cane pollen by germination on stigmas of a species of *Datura*.—*T. H. Kearney*.

1829. WEBBER, H. J. *Citrus root-stock problems*. California Citrograph 7: 391, 408-411. 7 fig. 1922.—This is a general discussion, with conclusions and recommendations about as in a previous publication [see Bot. Absts, 5, Entries 498-1785.] In the orchard test of large, intermediate, and small nursery trees the average size differences in 1922 were, with 1 slight exception, in the same sense as in 1919 (previously reported), and markedly in favor of the larger nursery trees. The large trees have also decidedly exceeded the smaller ones in yield. Similar results are now reported for a commercial orchard of 60 acres, of which successive thirds were planted respectively with large, intermediate, and small Valencia orange trees from the same nursery rows. Both commercial varieties and selected stock seedlings in orchard planting show great differences in size and vigor as well as in other characteristics; in view of this fact it is very probable that the persistent size differences among young budded trees are largely due to genetic differences among the stocks.—*Howard B. Frost*.

1830. WRIGHT, SEWALL. *Coefficient of inbreeding and relationship*. Amer. Nat. 56: 330-338. 1922.—Pearl has built up a coefficient of inbreeding based on the smaller number of ancestors in each generation back of an inbred individual as compared with the maximum possible number, and a partial inbreeding index which brings in coefficients of relationship between ancestors. The author suggests that a more direct measure of the effects of inbreeding may be obtained from the percentage of homozygosis which would follow on the average from a given system of mating, taking a formula which makes the coefficient run from 0 to 1 while the percentage of homozygosis is running from 50 to 100 per cent. The various formulae are developed from the method of path coefficients discussed by the author in a series of papers [see Bot. Absts. 10, Entries 143, 144, 145, 146, 147].—*Sylvia L. Parker*.

1831. ZADE. [German rev. of: (1) FRUWIRTH UND ROEMER. *Einführung in die landwirtschaftliche Pflanzenzüchtung*. (Introduction to agricultural plant breeding.) 150 p., 4 pl., 27 fig. Paul Parey: Berlin, 1921.] (2) BAUR, ERWIN. *Die wissenschaftlichen Grundlagen der Pflanzenzüchtung*. (The scientific principles of plant breeding.) 111 p., 6 pl., 11 fig. Gebrüder Borntraeger: Berlin, 1921 (see Bot. Absts. 12, Entry 1034.) Zeitschr. Indukt. Abstamm. -u. Vererb. 29: 139-140. 1922.—[See also Bot. Absts. 12, Entry 1784.]

HORTICULTURE

J. H. GOURLEY, *Editor*

(See also in this issue Entries 1562, 1585, 1600, 1623, 1626, 1631, 1775, 1776, 1820, 1823, 1825, 1829, 1882, 2129, 2132, 2134, 2157, 2158, 2159, 2218)

FRUITS AND GENERAL HORTICULTURE

1832. ANONYMOUS. [Report by the Netherlands Minister to China.] *Iets over de thee-cultuur in China*. [Note on tea culture in China.] De Thee 2: 53-54. 1921.—Tea is not cultivated in China on the same basis as in Ceylon, British India, and Java. It is rather a by-crop, grown in mixture with other crops, or on the dykes of rice fields. Direct seeding is practiced rather than the planting out of nursery stock. There is no pruning worthy the name. Picking is done only during about 3 weeks of the year, and by no special system. It is seldom that more than 3000 bushes are found under 1 ownership, and the factories have no control over the raw product. Better methods of handling the product must be practiced before Chinese tea can regain its importance in the market.—*Carl Hartley*.

1833. ANONYMOUS. *Sixteenth annual report of the government cinchona plantations and factory in Bengal for the year 1921-22*. 4 + xii p. Bengal Secretariat Book Depot: Calcutta,

1922.—The report gives the acreage in *Cinchona Legeriana*, and *C. succirubra* on different plantations as well as notes on the percentage of quinine secured, cost of production, extraction, packing, etc., including a detailed financial statement.—*A. J. Pieters*.

1834. ALLEN, W. J., and W. LEG. BRERETON. The packing of fruit. New South Wales Dept. Agric. Farmers Bull. 130. 46 p., 50 fig. 1920.—Detailed descriptions and illustrations are furnished for packing apples in the standard Australian bushel case. Variations in tiers, packs, and row counts allow for 21 different counts ranging from 45 to 210 fruits per case. Packing in the Canadian case is also illustrated and discussed. Brief notes are given for packing pears, peaches, and citrus fruits in cases and half cases. Eight standard packages are described in detail.—*L. R. Waldron*.

1835. BALLOU, F. H. Lessons from 1921 orchard work. Ohio Agric. Exp. Sta. Monthly Bull. 7: 63-67. 1922.—The author mentions briefly a few of the effects from neglect in spraying in southeastern Ohio due to the failure in the fruit crop. Observations are also given regarding the resistance of certain varieties to spring freezes.—*R. C. Thomas*.

1836. BALLOU, F. H. Response of sweet clover to phosphatic fertilizer. Ohio Agric. Exp. Sta. Monthly Bull. 7: 68-72. Fig. 1-3. 1922.—The conditions under which the test was conducted are briefly outlined. Certain advantages and disadvantages of sweet clover in orchard culture are mentioned. A test comparing the value of nitrate of soda alone at the rate of 200 pounds per acre, also with the addition of a similar amount of acid phosphate, demonstrated a very marked increase in yield of sweet clover due to the phosphatic fertilizer.—*R. C. Thomas*.

1837. BALLOU, F. H. Spraying hillside orchards. Ohio Agric. Exp. Sta. Monthly Bull. 7: 82-87. Fig. 1-5. 1922.—The writer presents methods of overcoming difficulties in spraying hillside orchards in southern Ohio. Special reference is made to the terraced roads and water supply. The illustrations accompanying the article are aptly chosen.—*R. C. Thomas*.

1838. BARKER, B. T. P. Root development in newly planted trees. Univ. Bristol Ann. Rept. Agric. and Hort. Res. Sta. 1920: 43-60. 1920.—This reports a study of root growth during the 1st year in the orchard of trees planted in the following ways: (1) root fibers retained, tree unrammed, branches pruned; (2) root fibers retained, tree unrammed, branches unpruned; (3) root fibers retained, tree rammed, branches pruned; (4) root fibers retained, tree rammed, branches unpruned; (5) root fibers removed, tree unrammed, branches pruned; (6) root fibers removed, tree unrammed, branches unpruned; (7) root fibers removed and roots cut, tree unrammed, branches pruned; (8) root fibres removed and roots cut, tree unrammed, branches pruned; (9) root reduced to short stump, tree unrammed, branches pruned; (10) root reduced to short stump, tree unrammed, branches unpruned. All were apple trees on Paradise roots. Trees having different root treatments were also planted in sand and others were grown with the roots in water.—With the trees in open ground there was no apparent difference in top growth on the different plots. Regardless of the treatment given very few new roots were formed except from that part of the main stock within 3-4 inches of the surface of the soil; this was true of 29 of the 30 trees lifted. New roots started from the older ones of 1 tree; this, it is thought, could not have been true Paradise stock.—With the trees growing in sand, new roots started from older roots from base to end. Apparently the larger number of new roots started near wounds made on the roots. As in the case of trees growing in soil the treatment of the roots at planting seemed to have no important influence on the character of the new root system.—The roots growing in water showed very great enlargement or callous-like growths of the lenticels. Both new root growth and this growth of lenticels slackened toward the end of the growing period, finally ceasing. The roots were then less resistant to the fungus growing upon them.—*W. H. Chandler*.

1839. BARKER, B. T. P., and A. H. LEES. Factors governing fruit-bud formation. (Pruning.) Univ. Bristol Ann. Rept. Agric. and Hort. Res. Sta. 1920: 19-42. 1920.—The paper

reports results of a study of the effect on fruit-bud formation of the method of pruning trees on supports advocated by Lorette in his book of 1913 (*La Taille Lorette*). It is naturally a study of very severe summer pruning. Thus, for wood shoots of 1 year's growth only, Lorette recommends cutting to 1-2 leaves at the base when the shoots are about the thickness of an ordinary lead pencil at the base, or about 10-12 inches long, or just beginning to lignify at the base; and for wood of more than 1 year's growth (short piece of wood of 1 or more year's growth) he recommends leaving 1 wood shoot (the weakest) and cutting it to 1 visible eye. He recommends leaving spurs and cutting to 1 eye any wood shoot that may be present. For treatment of twiggy shoots (*Brindilles*) he recommends cutting to 3 eyes or bending downward, and for the "bourses" or "knobs" (cluster bases), cutting to the basal leaf or to 2 visible eyes any wood shoots arising. The authors summarize their experience at Long Ashton (England) as follows: "(a) Pruning hard to obtain stipulary eyes for flower formation is very unsatisfactory. (b) Pruning to the basal cluster where present is far better, but results in occasional failures. (c) Where no basal cluster exists a cut to two visible eyes, not three, should be made. (d) The time of year, the state of lignification at the base and the presence or absence of basal clusters should be used for criteria rather than the length or thickness of the shoot. (e) *Brindilles* should be cut to two eyes where they cannot be safely left, not to three. The bending down method is hopeless except for a garden. (f) Shoots from bourses should be cut as close as possible, if carrying fruit; if not, treatment should be according to whether large dards are present or not." The results are discussed in relation to the theory of Loeb that growth inhibiting substance moves backward from the terminal portions of growing shoots. The authors think that results with this Lorette system of pruning are in agreement with Loeb's theory. Suggestions for practice in sections with rather humid climates like that of Long Ashton are given.—*W. H. Chandler*.

1840. [BERNARD, CH.] *Groenbemesters*. [Green manures.] *De Thee* 1: 100-101. 1920.—Ten reasons are given for the tea experiment station's regular recommendation that green manures be planted between the tea.—*Carl Hartley*.

1841. BERNARD, CH. *Het teeren van snoeiwonden*. [The tarring of pruning wounds.] *De Thee* 1: 15-17. 1920.—Tests were made on tea pruning wounds of 2 tars from a local petroleum company, 1 from a gas factory, and 1 from an unknown source. Application was delayed 1-2 days after pruning to allow the surfaces to dry. The petroleum "tars" proved variable, and consisted probably of asphalt dissolved in a light petroleum. The coal tar and the unknown tar penetrated deeply, especially in the cambium and bast regions, presumably due to phenol compounds. Discarding the yellow oil found separated out in the tins, and washing the residue with water before using, decreased the injury. The brownish tar from the petroleum company failed to cover the exposed wood properly. The black petroleum tar made a good cover, and at the end of a year good callus growth was noted. The results confirm earlier tests in showing the undesirability of phenol-containing tar-like substances for wound treatment.—*Carl Hartley*.

1842. [BERNARD, CH.] *Hoe lang blijft een thee-aanplant productief?* [How long does a tea plantation remain productive?] *De Thee* 1: 14-15. 1920.—Tea gardens that are well cared for should show no permanent diminution of yield up to the age of 20-30 years. A case of marked increase in yield following pruning and fertilization with boengkil (peanut or kapok seed cake), bone meal, and wood ashes is described.—*Carl Hartley*.

1843. [BERNARD, CH.] *Sesbania als groenbemester*. [*Sesbania* as a green manure.] *De Thee* 1: 18-19. 1920.—*Sesbania aegyptiaca* has given good results on some tea plantations, including places where lamtoro (*Leucaena glauca*) will not grow. It is a small tree, with light shade, easily propagated, and fast growing. Natives (in West Java) use its seed as a substitute for coffee, its foliage for fodder; they obtain a diuretic extract from the leaves, and in sections deficient in wood the tree serves as a source of fuel.—*Carl Hartley*.

1844. BERNARD, CH. *Verpakking van Formosa-thee*. [Packing of Formosa tea.] Dept. Landb. Nijv. en Handel [Nederland.-Indië] Proefsta. Thee Mededeel. 71. 3 p. 1920.—Formosa tea shippers by more careful grading and more durable packages have gained an advantage over Java tea shippers in the U. S. A. market.—*Carl Hartley*.

1845. BERNARD, CH. *Verslag van het Algemeen Proefstation voor Thee over het jaar 1920*. [Report of the General Experiment Station for Tea for the year 1920.] Dept. Landb. Nijv. en Handel [Nederland.-Indië] Proefsta. Thee Mededeel. 74. 64 p. 1921.—Brief report of the activities of the station, including those of the chemist, botanist, and agriculturist. The working plan and budget are given for 1921.—*Carl Hartley*.

1846. BERNARD, CH. *Verslag van het Proefstation voor Thee over het jaar 1919*. [Report of the Experiment Station for Tea for the year 1919.] Dept. Landb. Nijv. en Handel [Nederland.-Indië] Proefsta. Thee Mededeel. 69. 23 p. 1919.—This is the administrative report for 1919, budget for 1920, and report of the experimental garden, showing graphically the monthly yield and parallel rainfall and sunshine observations.—*Carl Hartley*.

1847. BERNARD, CH., EN C. P. COHEN STUART. *De theecultuur in Japan en in de Shanlanden*. 1. Enkele aantekeningen betreffende de theecultuur in Japan. 2. Gegevens betreffende de theecultuur in Siam en Burma. [Notes on tea culture in Japan, Siam, and Burma.] Dept. Landb. Nijv. en Handel [Nederland.-Indië] Proefsta. Thee Mededeel. 73. 34 p., 7 fig., 2 maps. 1920.—In addition to the Dutch text are given as appendices a letter in English from the Director of Agriculture of Burma describing the tea culture there; and a list, with accompanying maps, of places in Burma where either wild or cultivated tea is known to occur.—*Carl Hartley*.

1848. BERNARD, CH., EN M. KERBOSCH. *Voorloopige mededeeling omtrent het verenten van thee*. [Preliminary communications on the grafting of tea.] De Thee 1: 97-100. 2 pl. 1920.—Graftage is a promising method of perpetuating selected seed-stock. It has not been tested long enough to determine how much productiveness depends on root system and how much on the quality of the top. Ten years' experience however indicates that grafted plants, aside from growth vigor, have the habit and other characters of the scion parents. It is much more difficult to get successful grafts in tea than in *Cinchona*, methods which give 98 per cent with *Cinchona* succeeding in 20 per cent or less of the attempts with tea, the same experienced workers having been employed for both. Crown grafting, by a method illustrated in detail drawings, gave 50 per cent good unions and subsequent strong growth. Marcotting (girdling scion branches and letting them develop their own roots in balls of earth before removing them from the parent tree) gives good results and will be useful in selection work, though not adapted to large-scale operations.—*Carl Hartley*.

1849. BIOLETTI, FREDERIC T. *Some common errors in vine pruning and their remedies*. Univ. California Agric. Exp. Sta. Circ. 248. 8 p. 1922.—It is almost impossible to find 2 vines that should be pruned in exactly the same manner. Some of the errors in pruning are: (1) Failure to modify the pruning according to the strength of the vine or cane. This results in irregular crops and a decrease in quality. (2) Serious injury to the vine or its destruction by attempting to obtain excessive crops without regard to the annual growth. (3) Adopting systems which in their nature can not be permanent, i.e., vertical canes and vertical cordons.—*A. R. C. Haas*.

1850. BORZA, A. *Flora grădinilor țărănești române*. I. Mărul (*Pyrus Malus* L.) [The flora of the Roumanian peasant garden. I. The apple tree.] Bul. Inform. Grăd. Bot. Muz. Bot. Univ. Cluj 1: 64-87. 1921.—In this contribution are scientifically studied for the first time the apple types of Roumania. As a type *Malus pumila* Mill. is especially concerned in its varieties *domestica* C. K. Schneider and *dasyphylla* A. & G. Besides, there are forms which may be derived from *M. sylvestris* Mill. On the other hand, kinds derived from *M. baccata*

Borkh. are rare, and from *M. astracantha* Dum.-Cours. and *M. prunifolia* Borkh., it is scarcely possible to recognize descendants. In addition to a catalog of 150 local types, there are 27 types improved by the Saxons, Szklers and Magyars and 9 types of recent importation.—*M. Tiesenhausen*.

1851. BRADFORD, F. C. The relation of temperature to blossoming in the apple and the peach. Missouri Agric. Exp. Sta. Res. Bull. 53. 51 p., 5 pl., 4 fig. 1922.—The author presents data on temperature accumulation to the time of blossoming of peach and apple at several stations. The amount of heat measured in day-degrees received by peaches from Jan. 1 to blossoming varies with the season and varies more with the locality. Microscopic examination of the blossom buds of apple indicates different stages of advancement in the fall and different rates of development during winter in different varieties. Observations on branches forced in the greenhouse indicate that late blossoming in the apple is connected with rest period influence rather than different temperature requirements. Similar differences between varieties of peach seem to be masked at Columbia, Missouri.—*O. W. Letson*.

1852. BRADFORD, F. C., and H. A. CARDINELL. Observations on winter injury. I. Early and late winter injury. II. An aftermath of winter injury. Missouri Agric. Exp. Sta. Res. Bull. 56. 26 p., 8 pl. 1922.—I. The killing of fruit buds in the apple occurred early in 1921 and 1922. The Jonathan variety appeared to be injured to the extent of about 10 per cent, while other varieties were injured noticeably less or not at all. The evidence indicates that the injury was due to immaturity. The 2nd bloom was shown not be a result of injury to the normal bloom.—II. This portion of the bulletin contains observations made on a young orchard planted from nursery stock that had been injured by low temperature, while the more resistant cambium was not destroyed. When the trees were pruned they did not heal properly and several fungi gained entrance. Recommendations for dealing with such cases are given.—*O. W. Letson*.

1853. BUNYARD, E. A. Variegated fruits. Gard. Chron. 72: 168-169. 1922.—Cases of variegation in the fruits of orange, lemon, pear, apple, grape, currant, and gooseberry are noted. These variegations are found in green, red, pale, and yellow colors. In some varieties 3 of these color forms are known. These are supposed to originate as bud sports, and may occur in more than 1 locality, and for this reason claims for exclusive right of propagation can not be maintained.—*P. L. Ricker*.

1854. CARPENTER, FORD A. The trustworthiness of thermometers used by California fruit growers. Bull. Southern California Acad. Sci. 21: 21-27. Fig. 1-3. 1922.—The thermometers used by southern California fruit growers, especially since the war, have been noticeably inaccurate, only 6 per cent of those submitted to the practical research department of the Los Angeles Chamber of Commerce being accurate. Because of this inaccuracy great expense has been occasioned the fruit growers because of smudging when it was unnecessary. The sources of error, methods of calibration, proper placing of the thermometers in the orchard, and types of thermometers are discussed.—*Roxana Stinchfield Ferris*.

1855. CASTELLA, F. DE. Spring grafting of old-established vines. Jour. Dept. Agric. Victoria 18: 610-614, 680-687. Fig. 1-7. 1920.

1856. CASTELLA, F. DE. Twenty years of reconstitution. Jour. Dept. Agric. Victoria 18: 481-492. 1920.—This is a plea for the use of American vine stocks to combat the attacks of *Phylloxera*. The mild climate of Australia is favorable for success with *Phylloxera*-resistant stocks, especially if the best varieties are chosen and the soil carefully prepared. The effect of stock on scion is also discussed.—*Wm. E. Lawrence*.

1857. CHEVALIER, AUG. Comptes rendus du premier congrès du châtaignier. [An account of the first chestnut congress.] Rev. Bot. Appl. 1: 375-380. 1921.—A number of recent papers on the chestnut are reviewed.—*Paul Russell*.

1858. COHEN STUART, C. P. *De theezaadtuinen van Java en Sumatra*. [The tea seed gardens of Java and Sumatra.] Dept. Landb. Nijv. en Handel [Nederland.-Indië] Proefsta. Thee Mededeel. 75. 32 p., 13 fig. 1921. [With English summary.]—Tea seed growing is profitable, but when the 1,380 acres now in seed gardens become of full bearing age the local market will be over supplied and the poorer gardens forced out. The utilization of the seed of such gardens for oil extraction is suggested. A period of approximately $1\frac{1}{2}$ years intervenes between the formation of buds and the ripening of the seed, so that direct relation between climatic conditions and yield is not easily traced. In order to ensure full maturity, the taking of seed only after its fall from the tree is advised. Criteria for the selection of seed-tree stock are not yet absolutely established.—*Carl Hartley*.

1859. [COHEN STUART, C. P.]. *Hooge productie door zorgvuldigen pluk en insektenbestrijding*. [High production by careful picking and insect control.] *De Thee* 2: 5-7. 1921.—High yields at a Java tea plantation which picks only the pecco and 2 next leaves are reported. Extensive tests show that of the 4-leaf picking these first 3 leaves constitute 60 per cent by weight, the 4th leaf 26 per cent, and the oldest internode 14 per cent. Three-leaf picking however yields 66 per cent of the yield obtained in 4-leaf picking, due to the axillary bud of the leaf left on the plant.—*Carl Hartley*.

1860. COHEN STUART, C. P. *Iets over de middelen om oogstvermeerdering te verkrijgen*. [On the methods of getting increased yields.] *De Thee* 1: 46-49. 1920.—Brief consideration is given of picking system, soil conditions, pruning system, spacing, shade, disease control, and the hereditary qualities of the tea plants. The author has shown that a picking system including pecco and 1 leaf gives 200-300 per cent more yield than if the pecco only is taken; pecco and 2 leaves give a further increase of 150-200 per cent; 100-130 per cent further increase by a p+3 system; and 60-80 per cent further increase by a p+4 system.—*Carl Hartley*.

1861. COHEN STUART, C. P. *Nog iets over pluktermen*. [Something more about picking terms.] *De Thee* 1: 8-13. 1920.—This is an explanation of a number of terms, mainly Sundanese, in use in the Java tea industry.—*Carl Hartley*.

1862. COHEN STUART, C. P. *Snoeltermen*. [Pruning terms.] *De Thee* 2: 33-45. 3 fig. 1921.—Eight types of pruning are figured, and for each are given the Dutch and native names in use in West Java, and in some cases also the English name. Various Sundanese terms connected with pruning are also translated into Dutch, as for example the names of different kinds of branches, of pruning instruments, and of different methods of making the pruning cuts. Details of the different ways of making the individual cuts are illustrated.—*Carl Hartley*.

1863. [COHEN STUART, C. P.]. *Verzameling van leguminosen en onkruiden*. [Collection of legumes and weeds.] *De Thee* 2: 7-8. 1921.—The General Experiment Station for Tea [Buitenzorg, Java] is developing a herbarium including types and developmental stages of tea, relatives such as *Camellia* spp., the legumes used as green manures on tea estates, and the commoner weeds.—*Carl Hartley*.

1864. COLLINS, JAMES H. *How does fruit get damaged en route?* *Florida Grower* 26¹⁵: 6-7. 1 fig. 1922.—This is a general consideration of the strength of fruit boxes and types of nails and wood being used. The handling of boxes in fruit cars and their condition during transit until they reach the market are also discussed.—*J. C. Th. Uphof*.

1865. CRIDER, F. J. *The olive in Arizona*. *Arizona Agric. Exp. Sta. Bull.* 94. 493-528. 1922.—The author emphasizes the best practices in successful olive culture, based on investigations made by the Arizona Experiment Station during the past 26 years. The statement is made that Arizona may become one of the great olive-producing centers of the world because of the ideal climatic and soil conditions, absence of serious diseases and insects, and quality of the fruit produced.—*Herbert C. Hanson*.

1866. DEUSS, J. J. B. *Aluminium in plaats van lood voor theeverpakking.* [Aluminum in place of lead for tea packing.] *De Thee* 2: 24. 1921.—Aluminum is to be recommended. It has been shown however that lead is not dangerous for use in tea packing, as even mouldy tea in lead cases is entirely free from lead.—*Carl Hartley.*

1867. DEUSS, J. J. B. *De oolong thee van Formosa.* [The oolong tea of Formosa.] *De Thee* 2: 19-23. 1921.—The history and relatives of this tea are described, and a general account of tea culture in Formosa is given.—*Carl Hartley.*

1868. DEUSS, J. J. B. *De verpakking van Java-thee.* [The packing of Java tea.] *Dept. Landb. Nijv. en Handel [Nederland.-Indië] Proefsta. Thee Mededeel.* 71. 4-12, 14 fig. 1920.—Needed improvements in packing cases and packing methods are described.—*Carl Hartley.*

1869. DEUSS, J. J. B. *Grondbedekking in theetuinen.* [Mulching in tea gardens.] *De Thee* 1: 106-107. 1920.—Mulching with all sorts of available plant material has been tested on a large scale in a Java plantation, and the results appear excellent. Good physical condition, addition to soil humus, and weed control result. Alangalang, a coarse grass, is much employed; by laying the cut blades along the soil contours erosion is prevented.—*Carl Hartley.*

1870. DYKHUIS, J. *Italian fruit stocks.* *Nation. Nurseryman* 30: 312, 314. 1922.

1871. ELLENWOOD, C. W. *Notes on five year results of apple pruning.* *Ohio Agric. Exp. Sta. Monthly Bull.* 7: 58-61. 1922.—In an experiment to determine the relative value of no pruning, light summer pruning, light dormant pruning, heavy pruning, pruning after foliage appears, and light dormant pruning, it was found that the last method gave the most satisfactory result. The 5-year results from the various types of pruning, including in each plot 10 trees, are expressed in tabular form showing the number of pounds of fruit produced in each case classified as "firsts," "seconds," and total yield.—*R. C. Thomas.*

1872. G[ARRETSSEN], A. J. *Tijdelijk verlaten theetuinen.* [Temporarily abandoned tea gardens.] *De Thee* 2: 51-53. 1921.—The malaise has forced the temporary or partial abandonment of certain tea plantings. To prevent the development of jungle, difficult to eradicate when management is resumed, it is advised that gardens temporarily abandoned be first planted to some legume tall enough to shade out weeds, even though it also somewhat shade the tea. *Cajanus indicus* is recommended as a valuable fodder plant as well as soil improver. *Tephrosia candida* is less desirable because of slow growth, but can be used on poorer soils than the *Cajanus*. *Sesbania aculeata* does very well for the 1st year, but later not so well.—*Carl Hartley.*

1873. GEORGESON, C. C. *Report of work at Sitka station.* *Rept. Alaska Agric. Exp. Sta.* 1920: 12-20. *Pl. 1.* 1922.—According to this report some nursery stock suitable for Alaskan conditions was distributed and strawberry breeding work was continued. The growing of raspberries, currants, and gooseberries is reported. A hybrid between the Cuthbert raspberry and the native yellow salmonberry has been produced and named Bensonberry; it is a weak grower. Yellow Transparent and Livland Raspberry apples are recommended but no other tree fruits. Success with ornamental shrubbery, herbaceous perennials, and annual flowering plants is described. Hyacinths, tulips, and Narcissi are successful both indoors and out. Cabbage, cauliflower, onions, beets, turnips, peas, and celery are the vegetables reported. Of potatoes 45 varieties were grown in addition to 223 varieties originated at the station and known by numbers. Notes on the greenhouse and its management are given.—*J. P. Anderson.*

1874. GROVE, OTTO. *Single variety ciders and perries.* *Univ. Bristol Ann. Rept. Agric. and Hort. Res. Sta.* 1920: 86-90. 1920.—This report concerns the quality of cider or perry made from varieties of apples or pears.—*W. H. Chandler.*

1875. HAMMOND, A. A. **Small fruit culture. The gooseberry.** Jour. Dept. Agric. Victoria 18: 717-732. Fig. 16-30. 1920.—This report also treats of currants.—Wm. E. Lawrence.

1876. HAMMOND, A. A. **Small fruit culture. The raspberry.** Jour. Dept. Agric. Victoria 18: 672-679. Fig. 13-15. 1920.

1877. HEDRICK, U. P. **Cyclopedia of hardy fruits.** viii + 370 p., frontispiece, 16 pl. (colored and halftones), 325 fig. Macmillan Co.: New York, 1922.—This volume is designed as a successor to Downing's Fruits and Fruit Trees, Thomas' American Fruit Culturist, and other like volumes of the past century. It describes 104 species and 1,200 varieties, which list includes the fruits that are now grown in America. The author states that "The chief value of a book like this lies in the accuracy of the descriptions and of the determinations of synonyms. Herein the author has had an advantage over the old pomologists, since his connection with a modern experiment station with a large collection of fruits and a good horticultural library, has given him opportunity to describe first hand and pass impartial judgment on the varieties, and to go to original sources for names; whereas, the old writers, lacking these modern facilities were compelled to copy one from the other."—The ways in which the author designed the manual to be useful are: (1) to aid in the identification of varieties; (2) to guide in the choice of varieties; (3) to sort the names now in the use for varieties of hardy fruits and assign them to the varieties to which they belong; (4) to state in what regions the varieties described grow best; (5) to tell when and where the varieties originated; and (6) by depicting choice products of the orchard, to stimulate the desire to grow better fruits.—The volume was prepared for fruit-growers, nurserymen, students in colleges and high schools, county agricultural agents, and buyers of fruits. For the more elaborate and technical descriptions and historical accounts of varieties the specialist in pomology is referred to the series of fruit books prepared by the same author and published by the New York [Geneva] Agricultural Experiment Station.—J. H. Gourley.

1878. KERKHOVEN, A. R. W. **Lamtoro en kalkbemesting. [Lamtoro and lime fertilizing.]** De Thee 1: 18. 1920.—Lamtoro (*Leucaena glauca*) grows well in limestone outcrops where tea grows poorly, while in non-lime soils, where tea grows well, the lamtoro grows poorly. Various fertilizer tests on lamtoro gave good results whenever lime was included.—Carl Hartley.

1879. LAFFER, H. E. **The pruning of the vine.** New South Wales Dept. Agric. Farmers' Bull. 140. 42 p., 25 fig. 1921.—Eleven principles governing growth and fruit production are cited as a basis for practical pruning. Comparative advantages are discussed with reference to spur and rod pruning and the possibility of developing spurs and rods (under necessity) from water shoots. Methods of framework renewal are described. The following pruning systems are discussed and illustrated: (1) bush or goblet, (2) Thornery spalier, (3) multiple-armed spalier, (4) Bordelais spalier, and (5) Casenave's cordon. Brief notes are given on training the vine in the home garden. [See also Bot. Absts. 9, Entry 1425.]—L. R. Waldron.

1880. LARSEN, J. A. **Some characteristics of seeds of coniferous trees from the Pacific Northwest.** Nation. Nurseryman. 30: 246-249. 2 fig. 1922.—"Germination tests and observations on the characters of seeds of coniferous trees native to Montana and northern Idaho show that the seed is liable to serious injury by storage of the cones in wet condition; that the extraction of the seed under temperatures above 120°F. and in such hot and very humid air reduces the viability of the seed; that sterilization to prevent damping-off or bad molding is apt to injure seed of small, thin seed coats; that the rate of germination of seeds which ordinarily germinate slowly may be hastened materially by reduction of the impervious seed coat; and that coniferous seeds often remain viable in dry storage from eight to ten years."—J. H. Gourley.

1881. NESS, H. **Cultivation and care of trees on the farm in Texas.** Texas Agric. Exp. Sta. Bull. 293. 76 p. 1922.—Texas soils suitable for orchards are described. Plans for woodlots for shelter and other uses are given, together with the care and kinds of trees for each. Grafting and budding are briefly described and illustrated. Methods of planting and transplanting various trees are explained.—*L. Pace.*

1882. PRESCOTT, E. E. **Pomological committee conference at Hobart, April, 1920.** Jour. Dept. Agric. Victoria 18: 602-606. 1920.

1883. REINISCH, E. F. A. **The weakening effect on a species of plants of being continually reproduced by artificial means.** Trans. Kansas Acad. Sci. 30: 62-63. 1919/1921 [1922].—The methods of artificial reproduction, the history of Lombardy poplar and the necessity of, and the directions for, extreme care of its cuttings to prevent decay of the pith are discussed.—*F. C. Gates.*

1884. SAATHOFF. **Behelfskulturen für bedrohte Blumen- und Herrschaftsgärtnereien. I. Die Champignon-Kultur.** [Mushroom-culture.] Gartenwelt 26: 387-390. 5 fig. 1922.—Mushroom growing is described, as conducted by the firm Marquardt in Zossen. Two types of spawn are available, hard and loose, growers preferring the latter as it is easier to distribute over the beds. The beds are made in spring and summer, of horse manure from stables where the animals are fed on oats and hay. It is heaped and worked over for a period of 8 days and then mixed with dry leaves of linden (*Tilia*), donkey manure, and decayed sod. The mixture is placed in beds 40-50 cm. high and is compacted by tramping. When the soil temperature has gone down to 28°C. the spawn is planted. The mushrooms are grown in semi-darkness in cellars, stables, sheds, mines, catacombs, etc. Harvesting begins after 2-3 months.—*J. C. Th. Uphof.*

1885. SCOTT, L. B. **Progress of nursery stock investigations by Department of Agriculture, U. S. A.** Nation. Nurseryman 30: 198, 200. 1922.

1886. SIAHAJJA, E. L. **Een vergelijking van keprisan en schoonsnoei.** [A comparison of skiffing and stick pruning.] De Thee 2: 45-48. 1921.—The 2 methods are compared in detail in 11 respects. The former is cheaper and quicker, it results in earlier production, but must also be repeated sooner, and results in decreased productivity in later years and more damage from *Helopeltis* if the insect is not combatted. Skiffing, however, facilitates 1 method of *Helopeltis* control and yields better grade tea. Various factors control choice of the pruning method. In young vigorous gardens skiffing gives excellent results, while in old gardens it results in 1 excellent flush and practically nothing more. The comparison is for skiffing and stick pruning made at equal height above the ground.—*Carl Hartley.*

1887. SKVORTZOW, B. W. **Notes on the agriculture, botany, and zoology of China.** Jour. North China Branch Roy. Asiatic Soc. 52: 79-111. 9 fig. 1921.—Chiefly economic data are presented on poppy culture, mountain rice, apricots, plums, fruit culture at Foochow, etc. The paper presents in addition slightly over 7 pages devoted to a bibliography of the botany, zoology, and rural economy of Manchuria, the papers being very largely by Russian authors.—*E. D. Merrill.*

1888. SMITS, J. P. **Keprisan en schoonsnoei.** [Skiffing (top pruning) vs. stick pruning.] De Thee 1: 72-73. 1920.—Experience on the author's plantation in Java indicates that the skiffing of tea gives better results on poor soils than on good soils. This is attributed to the fact that on the good soils the skiffing results in such heavy production of "Chanji leaves" (resting buds) that it is impossible to maintain clean picking unless exceptionally large forces of pickers are available. This "Chanji leaf" production is therefore not replaced by pecco and in 8 months another pruning is needed.—*Carl Hartley.*

1889. VINSON, A. E., F. J. CRIDER, and G. E. THOMPSON. **The Yuma Mesa.** Arizona Agric. Exp. Sta. Bull. 89. 225-263. 1919.—A commission consisting of an agricultural chemist, a horticulturist, and an agronomist studied the soils, climatology, and crops grown on the Yuma Mesa. The following factors make this region of the greatest promise for citrus culture: efficient shipping facilities, favorable soil and irrigation water, freedom from citrus pests, and the smallest rainfall, lowest relative humidity, and greatest percentage of sunshine of any citrus region in North America. The commission recommends that the Mesa be brought under irrigation and developed by the growing of citrus and other sub-tropical fruits.—*Herbert C. Hanson.*

1890. VON OVEN, F. W. **Selecting superior varieties.** Amer. Bot. 28: 153-154. 1922.—Emphasis is placed upon the desirability of noting superior varieties, as shown by the character of leaves, flowers, or fruits as they occur in the open.—*S. P. Nichols.*

1891. WALLACE, T. **Trial cider orchards.** Univ. Bristol Ann. Rept. Agric. and Hort. Res. Sta. 1920: 91-95. 1920.—A report is made of mechanical and chemical analyses of the soils of some of the trial cider orchards.—*W. H. Chandler.*

1892. WHITTLE, C. A. **The pineapple pear.** Florida Grower 28¹²: 5. 1922.—This pear variety is resistant to blight and is valued more than Kiefer by canners. The yield is exceedingly heavy. Only a few orchards in the South are planted to this variety.—*J. C. Th. Uphof.*

1893. WICHMANN, H. J. **Report on determination of pectin in fruit and fruit products.** Jour. Assoc. Official Agric. Chem. 6: 34-40. 1922.—The present tentative official method of determining pectin by alcohol precipitation is unreliable and a new method is submitted.—*F. M. Schertz.*

1894. WILDEMAN, E. DE. **Quelques considérations sur les bananiers.** [Notes on bananas.] Rev. Bot. Appl. 1: 241-269. 1921.—The writer has sought for several years to arouse interest in this group of plants, especially those varieties found wild and cultivated in central Africa. He believes that certain species of *Musa* are indigenous to central Africa, though this region need not be considered as the original source of all bananas. A number of recent papers and books on the banana are discussed, including the well known book by Fawcett, published in 1913; O. W. Barrett's paper in Philippine Agric. Rev. July, 1912; Robertson Proschowsky's paper in Petite Rev. Agric. et Hort. July 8, 1917; and the article by W. J. Allen and R. G. Bartlett in Agric. Gaz. New South Wales [see Bot. Absts. 7, Entry 947]. These publications only go to show the necessity of a profound study of the entire question in all of its aspects; this study should include consideration of the distribution of the species and varieties, detailed examination of each species and variety, with the particular uses and cultural requirements of each. The banana wilt and other diseases and also insect pests should be thoroughly investigated. The species of *Musa* discussed include *M. sapientum*, *M. paradisiaca*, *M. Cavendishii*, *M. textilis*, *M. religiosa*, *M. arnoldiana*, *M. ensete*, *M. superba*, *M. rosacea*, and *M. Gilletii*. Two analyses of the common banana are given to show the food value, and the banana as a source of alcohol is briefly considered.—*Paul Russell.*

FLORICULTURE AND ORNAMENTAL HORTICULTURE

1895. ANONYMOUS. **Display of perennial asters.** Brooklyn Bot. Gard. Rec. 11: 121-122. 1922.—The 1st season's results with varieties of *Aster novae-angliae*, *A. novi-belgii*, and *A. Amellus* grown in 1922 at Brooklyn Botanic Garden are recounted. The plants were obtained from Aldenham House gardens, near London.—*C. S. Gager.*

1896. ANONYMOUS. **Old garden flowers. III.** Amer. Bot. 28: 95-97. 1922.—*Monarda* is considered.—*S. P. Nichols.*

1897. ANONYMOUS. **The Dahlia.** Gard. Chron. 72: 164. 1922.—Notes are given on the recent exhibition of the National Dahlia Society and a brief discussion of the introduction of the Dahlia into England.—*P. L. Ricker.*

1898. ANONYMOUS. [Rev. of: TRELEASE, WM. **Plant materials of decorative gardening: The woody plants.** 2d ed. rev., xliii + 177 p. The Author: Urbana, Illinois, 1921.] Nature 110: 177. 1922.

1899. BIRD, HENRY. **Gardening in an artificial bog.** Amer. Bot. 28: 97-102. 1922.—Directions for making and planting an artificial bog are given.—*S. P. Nichols.*

1900. BROTHERSTON, R. P. **Calceolaria.** Gard. Chron. 72: 52. 1922.—Annual species were introduced into cultivation a century ago, but the first shrubby species as early as 1777. The history of their cultivation and some of the literature are reviewed.—*P. L. Ricker.*

1901. DRESSEL, JOH. **Treiben von Zwerg Iris—Iris pumila.** [Forcing of the dwarf Iris.] Möllers Deutsch. Gärtnerzeitg. 37: 206. 1922.—At the beginning of winter the rhizomes of *Iris pumila* are placed in boxes 12-15 cm. high; if planted too deep they rot. These boxes are set in frames free from frost and early in February they are placed in a hothouse, close under the glass. They flower March-May.—*J. C. Th. Uphof.*

1902. DYKES, W. R. **Iris conference.** Gard. Chron. 71: 325-326. 1922.—Held at Vincent Square, London, June 7 and 8, the conference brought together the best collectors of garden varieties of bearded Irises ever shown in the Hall. Extended notes on exhibits and exhibitors are given.—*P. L. Ricker.*

1903. GRIMM, KARL. **Mehr Cyclamen-Blumen zum Pflücken im Winter.** [More cyclamen flowers in winter.] Möllers Deutsch. Gärtnerzeitg. 37: 205-206. 2 fig. 1922.—The author emphasizes the fact that cyclamen should be grown in winter for the cut-flower industry. The newer varieties especially develop colors valuable for bouquets. Only the finest and largest flowers should be grown.—*J. C. Th. Uphof.*

1904. JACOB, JOSEPH. **Select bulbs for 1922.** Gard. Chron. 72: 150. 1922.—Notes are given on tests of recent varieties.—*P. L. Ricker.*

1905. JUNGE, HEINRICH. **Aster ericoides "Schneetanne" und Aster vimineus "Erlkönig."** Möllers Deutsch. Gärtnerzeitg. 37: 209. 1 fig. 1922.—The small flowering herbaceous *Aster ericoides* Schneetanne and *A. vimineus* are recommended as the best of this type. They flower from September until the middle of October.—*J. C. Th. Uphof.*

1906. O'B., J. **Yellow Dendrobiums.** Gard. Chron. 72: 125. Fig. 52. 1922.—Distribution of yellow species in nature, their hybridization, and the varieties are discussed.—*P. L. Ricker.*

1907. PROSCHOWSKY, A. ROBERTSON. **Palms of the Riviera.** Gard. Chron. 71: 317. 1922.—The genus *Livistona* is well known to gardeners, but not sufficiently planted on the Riviera. *L. chinensis* was until recently the most cultivated palm in the market, but now is being replaced by *Howea forsteriana*. The former are more graceful fan palms with more beautifully shaped leaves than those covered in previous article. Some are of remarkable size, ranging up to 8-10 m. in height, but are very slow growing.—*P. L. Ricker.*

1908. PROSCHOWSKY, A. ROBERTSON. **Palms of the Riviera.** Gard. Chron. 72: 66. Fig. 28. 1922.—*Livistona australis* is figured and compared with related palms on the Riviera.—*P. L. Ricker.*

1909. TREVITHICK, W. E. **Metamorphosis of Rhododendron inflorescence.** Gard. Chron. 72: 123. Fig. 50. 1922.—A form resembling some double forms of *Camellia* found at Kew on *R. corona* is figured and described.—P. L. Ricker.

VEGETABLE CULTURE

1910. BEATTIE, W. R. **Peat soils in vegetable production.** Jour. Amer. Peat Soc. 15: 28-32. 1922.—These soils are valuable for the production of lettuce, celery, and onions, and the possibilities with other crops have scarcely been touched upon.—G. B. Rigg.

1911. GLEISBERG, W. **Gemüsesorten und Pflanzenzüchtung.** [Vegetable varieties and plant breeding.] Gartenwelt 26: 370-372. 1922.—Varieties of vegetables should be examined as to their purity, for a great number of commercial varieties belong to "a population" instead of to a pure line. In 17 seed catalogues there were too many varieties of the same type. Of white cabbage there were 26 varieties which are early and round, 10, early and pointed 25, late and round, and 6, late and pointed.—J. C. Th. Uphof.

1912. SCHMIDT, J. C. **Buschbohne Wachs Schlossperle.** [Dwarf bean "Wachs Schlossperle."] Möllers Deutsch. Gärtnerzeitg. 37: 213. 2 fig. 1922.—This is an account of a white bean, produced from a colored variety. It has a fine flavour, is very productive, and is 10-12 days earlier than Wachs (wax) Flageolet.—J. C. Th. Uphof.

HORTICULTURE PRODUCTS

1913. ALLEN, W. J., and J. M. ARTHUR. **Some experiments in drying apricots.** Agric. Gaz. New South Wales 33: 738. 1922.—The methods used are described and tabulated.—L. R. Waldron.

1914. CHACE, E. M. **By-products from citrus fruits.** U. S. Dept. Agric. Dept. Circ. 232. 13 p. 1922.

1915. DEUSS, J. J. B. **Eenvoudige oven om kleine hoeveelheden thee af te drogen.** [Simple oven for drying small quantities of tea.] De Thee 1: 79-80. 1 fig. 1920.—An oven successfully used on a small plantation in Java is described and diagrammed.—Carl Hartley.

1916. DEUSS, J. J. B. **Over coffeine bereiding uit theeblad en thee.** [Concerning the preparation of caffeine from tea leaf and tea.] De Thee 2: 62-63. 1921.—The 1st and 2nd leaves contain 4.3 per cent, and the 5th and 6th, 1.5 per cent, of caffeine. Tea prunings yielded 2.3 per cent, and the "fluff" from the leaves 2.25 per cent.—Carl Hartley.

1917. DEUSS, J. J. B. **Resultaten van de enquête over het drogen. I.** [Results of the questionnaire on drying. I.] De Thee 1: 112-117. 1920.—Data are given on the performance of various makes of tea-drying machines obtained by a questionnaire addressed to Java tea growers.—Carl Hartley.

1918. DEUSS, J. J. B. **Resultaten van de enquête over het drogen. II.** [Results of investigation of drying. II.] De Thee 2: 16-19. 1921.—A comparison of 2 drying installations for tea is made.—Carl Hartley.

1919. DEUSS, J. J. B. **Verpakking van thee in vetpapier in plaats van lood.** [Packing tea in oiled paper instead of lead.] De Thee 1: 119-120. 1920.—Oiled paper is used for small packages of tea in Holland, but cannot be employed in the moist atmosphere of West Java, even in retail trade, the tea so packed becoming thoroughly moulded in 2 months. Packing in paraffin paper and so-called parchment paper also failed. For some reason, even tea kept in glass-stoppered jars or sealed glass tubes moulds more quickly than tea kept in lead containers which have been closed merely by folding. Perhaps too tight closure is undesirable.—Carl Hartley.

1920. HEIDE, VON DER. Neuere Erfahrungen auf dem Gebiete der Weinbehandlung insbesondere der Obstweine. [New experiences in handling wine, especially fruit wine.] Mitteil. Deutsch. Landw. Ges. 37: 687-692. 1922.—In this address the author spoke at length on some of the factors influencing wine making. The following subjects were discussed: pure yeasts; acidity changes; artificial decrease and increase in acidity; the absorption of acid from burning sulphur; filtering and purifying; the addition of water and sugar.—A. J. Pieters.

1921. HILTS, R. W. Report on the determination of moisture in dried fruits. Jour. Assoc. Official Agric. Chem. 6: 40-48. 1922.—Results of moisture determinations on peaches, pears, and apricots, using vacuum and water-oven methods, are reported.—F. M. Schertz.

1922. KNAUTH, ANDREAS. Obstsorten für die Dauerwarenherstellung. [Fruit varieties for preserving.] Gartenwelt 26: 369-370. 1922.—This is a general account from Germany of various varieties of fruits suitable for preserves, cider, etc.—J. C. Th. Uphof.

MORPHOLOGY, ANATOMY AND HISTOLOGY OF VASCULAR PLANTS

E. W. SINNOTT, *Editor*

(See in this issue Entries 1824, 1838, 1909, 2016, 2048, 2056, 2066, 2085, 2218)

MORPHOLOGY AND TAXONOMY OF ALGAE

E. N. TRANSEAU, *Editor*

L. H. TIFFANY, *Assistant Editor*

(See also in this issue Entries 1947, 2066)

1923. BATTEN, L. Organs of attachment in Polysiphonia. [Abstract.] Rept. Brit. Assoc. Adv. Sci. 1921: 452. 1921.

1924. BRUCK, ERWIN. Experimentelle Untersuchungen an den Schwärmern von Chromulina Rosanoffii (Bütschli). [Experimental studies of the swarm spores of Chromulina Rosanoffii.] 8 vo, 49 p. Diss. Breslau, 1921.

1925. DVOŘÁK, R. Sur la recherche des algues en Moravie. [On the study of algae in Moravia.] Nuova Notarisia 33: 135-138. 1922.—A brief review is presented of the results of studies of the algae of Moravia and Bohemia, especially by Nave, Richter, Dvořák, Prát, and Fischer, and with dates of publication ranging from 1863 to 1920.—Marshall A. Howe.

1926. FUNK, GEORG. Über einige Ceramiaceen aus dem golf von Neapel. [Some Ceramiaceae from the Gulf of Naples.] Beih. Bot. Centralbl. II Abt. 39: 223-247. Pl. 5. 1922.—Habitats and associated plants are given and a summary of the Ceramiaceae found in the Gulf of Naples is added. *Vickersia canariensis* Karsakoff var. *mediterranea* is described as new. *Dohrniella* is proposed as a new genus, with *D. neapolitana* a new species. *Ceramium Bertholdi* and *Callithamnion Aegagropilae* are new species.—L. Pace.

1927. HUFF, N. L. Copper sulphate for preventing algal growths in lakes and reservoirs. Engineering and Contracting 58: 33-36. 1922.—The copper sulphate method of control or destruction of algal growths is described under the method of application, the amount required, and the effect of the chemical on fish life.—H. H. Wagenhals.

1928. MAMELI, EVA. Sulla costituzione chimica della membrana delle alghe Cianoficee. [On the chemical constitution of the membrane of the Cyanophyceae.] Atti Ist. Bot. Univ. Pavia 17: 257-264. 1920.—The chemical constitution of the membrane of the Cyanophyceae has been known for only a small number of genera and with some lack of uniformity in results; there has been in particular some uncertainty as to whether cellulose is present in all. The

present research is based upon 34 genera, represented by about 100 species, including a few lichen-forming species, which give the following conclusions: (1) cellulose is present in general in the membranes of all the Cyanophyceae, a result that harmonizes the chemical behavior of the dermatoplasm of these algae with that of the vegetal cell in general; (2) the cellulose is usually accompanied by a pectic substance; (3) the search for chitin gave negative results; (4) the products of hydrolysis of the cellulose of the Cyanophyceae thus far met with are pentosans and galactans. The membrane of the Cyanophyceae is then, in general, of a pectic-cellulose nature.—*Marshall A. Howe.*

1929. MAZZA, ANGELO. Aggiunte al saggio di algologia oceanica. [Appendix to the essay on oceanic algology.] *Nuova Notarisia* 33: 1-31, 97-125. 1922.—The author continues his systematic and morphological studies of the Florideae of the world. The species particularly described and discussed are *Leptocladia Binghamiae*, *L. conferta*, *Nitophyllum Curdieanum*, *N. Durvillei*, *Botryoglossum violaceum*, *B. Ruprechtianum*, *Phytomorpha imbricata*, *Schizoneura Davisii*, *Ptilonia magellanica*, *Bonnemaisonia hamifera*, *Ricardia Montagnei*, *Laurencia perforata*, *L. spectabilis*, *Coeloclonium opuntioides*, *Chondria foliifera*, *C. debilis*, and *C. crassicaulis*.—*Marshall A. Howe.*

1930. SETCHELL, WILLIAM ALBERT, and NATHANIEL LYON GARDNER. Phycological contributions. II to VI. *Univ. California Publ. Bot.* 7: 333-426. *Pl.* 32-49. 1922.—The "contributions" and their contents of novelties are as follows:—II. New species and new forms of *Myrionema*: *M. primarium*; *M. primarium* f. *acuminatum*; *M. minutissimum*; *M. foecundum* f. *simplicissimum*, *subulatum*, *ramulosum*, *divergens*, and *majus*; *M. coronae* f. *uniforme*, *angulatum* and *sterile*; *M. balticum* f. *pedicellatum* and *californicum*; *M. globosum* f. *affine*; *M. compsonematoides*; *M. hecatonematoides*; *M. attenuatum*; *M. attenuatum* f. *doliiforme*; *M. phyllophilum*; *M. setiferum*; *M. obscurum*.—III. New species and new forms in *Compsonema*: *C. streblonematoides*, *C. intricatum*, *C. fructuosum*, *C. pusillum*, *C. speciosum* f. *piliferum*, *C. sporangiiferum*, *C. sessile*, *C. tenue*, *C. nummuloides*, *C. fasciculatum*, *C. myrionematoides*, *C. secundum*, *C. ramulosum*, *C. serpens*, *C. coniferum*, *C. dubium*, *C. secundum* f. *terminale*.—IV. New species of *Hecatonema*; *H. variabile*, *H. clavatum*, *H. Lawsonii*.—V. New species of *Pylaiella* and *Streblonema*: *Pylaiella tenella*, *P. unilateralis*, *Streblonema Porphyrae*, *S. myrionematoides*, *S. penetrans*, *S. vorax*, *S. scabiosum*, *S. evagatum*, *S. rugosum*, *S. transfixum*, *S. corymbiferum*, *S. anomalum*, *S. Johnstonae*. *S. aecidioides* f. *pacificum* appears as a new form, and *S. investiens* (Collins) as a new combination.—VI. New species of *Ectocarpus*: *E. affinis*, *E. chantransioides*, *E. commensalis*, *E. eramosus*, *E. flagelliferus*, *E. flocculiformis*, *E. fructuosus*, *E. granuloides*, *E. Mesogloiae*, *E. Saundersii*, *E. simulans*, *E. socialis*, *E. Taoniae*. Further are to be noted: *Ectocarpales* nom. nov.; *Ectocarpus acutus* nom. nov.; *E. confervoides* f. *parvus* (Saunders) comb. nov.; *E. cylindricus* f. *typicus* nom. nov.; *E. cylindricus* f. *codiophilus* f. nov.; *E. cylindricus* f. *acmaeophilus* f. nov.; *E. siliculosus* f. *subulatus* (Kuetz.) comb. nov.—*W. A. Setchell.*

1931. SHAW, W. R. *Copelandosphaera*, a new genus of the Volvocaceae. *Philippine Jour. Sci.* 21: 207-232. *Pl.* 1-4. 1922.—A new species is made the type of a new genus under the name *Copelandosphaera dissipatrix*. It differs from *Volvox* and *Janetosphaera* in having no protoplasmic connections between the cells, and also in having the gonidia differentiated from the somatogenic cells before the last cell divisions in the growth of the coenobium. It differs from *Campbellosphaera* and *Merrillosphaera* in having the gonidia differentiated late in the embryonic development. It is unlike *Campbellosphaera* in not having its gonidia marginal and migratory, and is unlike *Merrillosphaera* in not having regular numbers of gonidia with geometrically symmetrical arrangement. Bisexual individuals produce many oogonidia and a few androgonidia that are of about the same size. An American species (*V. spermatosphaera*) is included in this new genus.—*E. D. Merrill.*

1932. SKOTTSBERG, CARL. Notes on Pacific Coast algae, II. On the Californian "*Delesseria quercifolia*." *Univ. California Publ. Bot.* 7: 427-436. *Pl.* 50. 1922.—The author

shows that the red alga of the Pacific Coast of North America which has generally passed under the name of *Delesseria quercifolia* Bory is not of that species. He names it *Phycodrys Setchellii* sp. nov.—W. A. Setchell.

1933. SKVORTZOW, B. W. Notes on the agriculture, botany, and zoology of China. Jour. Roy. Asiatic Soc. North China Branch 53: 189-195. 1922.—The author includes a list of 21 fresh-water algae from Fukien; no new names appear.—E. D. Merrill.

1934. STRØM, K. MÜNSTER. Some algae from Merano. Nuova Notarisia 33: 126-134. Fig. 1-2. 1922.—An annotated list is given of 43 species of freshwater algae, collected in the autumn of 1921 in the vicinity of Merano, in what is now the Italian Tirol, mostly at an elevation of 5,500-5,720 feet. *Cosmarium Majae* sp. nov. is described and figured.—Marshall A. Howe.

1935. TEREG, ELINOR. Einige neue Grünalgen. [Some new green algae.] Beih. Bot. Centralbl. II Abt. 39: 179-195. Pl. 1-2. 1922.—The cultural methods used are given. The following species are described as new: *Stenoplana Bertholdi*, *Bracteacoccus aggregatus*, *Chlorococcus intumescens*, *Tetracoccus cartilagineus*, *Chlorosarcina cumuliformis*.—L. Pace.

MORPHOLOGY AND TAXONOMY OF BRYOPHYTES

ALEXANDER W. EVANS, *Editor*

(See also in this issue Entries 1972, 2066)

1936. AMANN, J. Le *Bryum Schleicheri* Schwaegr. Rev. Bryologique 49: 25-28. 1922.—According to the descriptions of Limpricht and Roth, *Bryum Schleicheri* Schwaegr. is distinguished from the closely related *B. turbinatum* (Hedw.) Schwaegr. by its long-decurrent leaves. The author shows that this difference was based on a misconception and that the leaves in both species are slightly or not at all decurrent. He separates the species by means of other anatomical differences in the leaves and calls attention to 2 exotic relatives of *B. Schleicheri*—one from Chile and the other from India.—A. W. Evans.

1937. DOUIN, R. Le sporophyte des Marchantiées. [The sporophyte of the Marchantieae.] Rev. Gén. Bot. 34: 321-335. Pl. 12-13, 4 fig. 1922.—It is shown that the sporophytes of the Marchantieae are fully as diverse as those of the Jungermanniales. Throughout the group a differentiation into foot, seta, and capsule is everywhere apparent, and the author first discusses these parts in detail, laying especial emphasis on the structure of the capsule-wall and the various methods of dehiscence. He then describes the parts that protect the sporophyte during its development and points out their importance from the standpoint of classification. These parts include the calyptra, the involucre, and the perianth, the last being present in only 4 genera.—J. C. Gilman.

1938. HUSNOT, T. Hepaticologia Gallica. Flore analytique et descriptive des Hépatiques de France et des contrées voisines. [Gallic hepaticology. Analytic and descriptive flora of the Hepaticae of France and neighboring countries.] 2nd ed., 163 p., 23 pl., Cahan par Athis (Orne), France, 1920.—The 1st edition of this manual on French Hepaticae was published in 1881 and included 45 genera and 174 species; the 2nd edition, which is essentially a new work, includes 80 genera and 289 species. In a short introduction the general morphology of the Hepaticae is described, and directions are given for collecting and studying specimens. The work then proceeds to the description of the species, genera, and larger groups represented, artificial keys being provided wherever necessary. The Hepaticae are first divided into the 3 grand divisions Jongermanniaceés, Marchantiaceés, and Anthocérotoceés; and the Jongermanniaceés are subdivided into the Acrogynes and the Anacrogynes. The Acrogynes are then subdivided into the following tribes: Jubulées (5 genera and 23 species), Madothecées (1 genus and 6 species), Pleuroziées (1 genus and 1 species), Radulées (1 genus and 6 species), Scapaniées (2 genera and 24 species), Blepharoziciées (7 genera and 9 species), Cephaloziciées

(11 genera and 52 species), and Lophoziaées (23 genera and 101 species). The Anacrogynes yield the tribes Haplomitriées (1 genus and 1 species), Fossombroniées (4 genera and 11 species), Dilénées (2 genera and 4 species), Metzgeriées (2 genera and 10 species), Riellées (1 genus and 2 species) and Sphérocarpées (1 genus and 2 species); while the Marchantiacées are directly divided into the tribes Marchantiées (13 genera and 19 species), Targioniées (1 genus and 1 species), Corsiniées (1 genus and 1 species), and Ricciées (2 genera and 10 species). The Anthocérotaées, which are not subdivided into tribes, include 2 genera and 6 species. As a rule the species are understood in a broad sense, so that some of the so-called "small" species described during recent years are either totally ignored or reduced to varietal rank. Under each species data are given regarding the local distribution within the region studied and also the general distribution, in the case of species extending beyond this region. The plates comprise about 1,800 separate figures. These represent the species described in natural size and also with enlarged details.—A. W. Evans.

1939. H[USNOT], T. [Rev. of: DAVY DE VIRVILLE, AD., et ROBERT DOUIN. Sur les modifications de la forme et de la structure des hépatiques maintenues submergées dans l'eau. (Concerning the modifications of form and structure of hepatics brought about by maintaining them under water.) Compt. Rend. Acad. Sci. Paris 172: 1306-1308. 1921 (see Bot. Absts. 10, Entry 603).] Rev. Bryologique 49: 32. 1922.—The reviewer (in a footnote) calls attention to the various forms assumed by *Hypnum cupressiforme* under different environmental conditions and intimates that such forms, in the case of a less common moss, would be treated as distinct species, to the detriment of science.—A. W. Evans.

1940. LOESKE, L. Adventive Moose bei Berlin. [Adventive mosses in the vicinity of Berlin.] Bryol. Zeitschr. 1: 138, 140. 1918.—Attention is called to a series of mosses apparently introduced into the Berlin flora. Some of these were found on boulders in the Botanical Garden at Dahlem and the others on oak logs from Bohemia piled up at Strausberg. Of the species listed from Dahlem the following are otherwise unknown in the district under consideration: *Anomodon attenuatus*, *Barbula reflexa*, *Brachythecium laetum*, and *Grimmia Hartmanni*. Of the Strausberg species *Antitrichia curtipendula* and *Leskea nervosa* are the most interesting, the *Leskea* being new to the region.—A. W. Evans.

1941. L[OESKE], L. Zur Bryogeographie Mitteleuropas. [On the bryogeography of Central Europe.] Bryol. Zeitschr. 1: 142-144. 1918.—The author gives notes on the distribution of 14 mosses in Central Europe. Among the more interesting of these are the following: *Barbula flavipes*, new to Thuringia; *Catoscopium nigrum*, new to East Prussia; *Dichelyma capillaceum*, new to western Europe; *Mnium cinclidioides*, new to the March of Brandenburg; *Orthothecium intricatum*, new to the Harz Mountains; and *Plagiobryum Zierli*, new to the Black Forest.—A. W. Evans.

1942. MAHEU, JACQUES. Sur une tardive régénération de mousse. [On a delayed regeneration in a moss.] Compt. Rend. Acad. Sci. Paris 174: 1124-1126. 10 fig. 1922.—The author describes the regeneration of *Barbula muralis* Hedw. in material that had been kept dry for 14 years. When placed in a humid atmosphere some of the leaf cells gave rise to short filaments each of which bore a rounded unicellular gemma at the tip. Upon becoming detached this developed into a typical moss protonema upon which a lateral bulblet was produced, this bulblet growing directly into a diminutive leafy shoot. The various steps in the process are figured.—C. H. Farr.

1943. MOENKEMEYER, W. Ueber *Hypnum turgescens* und *trifarium*. [On *Hypnum turgescens* and *H. trifarium*.] Bryol. Zeitschr. 1: 140, 141. 1918.—The author expresses the opinion that *Hypnum turgescens* T. Jens. is not closely related to *H. trifarium* and *H. stramineum*, as certain authors have stated or implied. He thinks that these 2 species are clearly referable to the genus *Calliargon*, while *H. turgescens* is so closely related to *H. scorpioides* L., a member of the genus *Scorpidium*, that he reduces it to varietal rank, giving it the name *Scorpidium scorpioides* var. *turgescens* (T. Jens.) Moenkemeyer. In connection with *Calliargon stramineum* he describes a new var. *patens*, basing it on various European specimens.—A. W. Evans.

1944. PAUL, H. Ueber *Hypnum turgescens* T. Jensen, eine systematisch-geographische Studie. [On *Hypnum turgescens*, a systematic-geographic study.] *Bryol. Zeitschr.* 1: 145-160. 8 fig. 1918.—In this paper, which is not yet completed, the author discusses the relationships of *H. turgescens* to other hypnoid mosses and gives an account of its geographical distribution and vegetative reproduction. After summarizing the involved synonymy of the species he reaches the conclusion that it is distinct from *H. scorpioides* L., to which Moenkemeyer had reduced it as a variety [see previous entry]. He refers both species to the genus *Scorpidium* of which he gives a revised description, laying especial emphasis on the variability of the leaf-nerves, on the poorly defined alar cells, on the concavity of the leaves, and on the absence of rhizoid-initials among the leaf-cells. As thus amended the genus includes the following 4 species, 2 of which represent new combinations: *S. lycopodioides* (Brid.), *S. scorpioides* (L.) Limpr., *S. turgescens* (T. Jens.) Loeske, and *S. trifarium* (Web. & Mohr.). In addition to these the following new combinations, based on northern species, are tentatively proposed: *S. brevifolium* (Lindb.), *S. latifolium* (Lindb.), and *S. longicuspis* (Lindb. & Arnell). From the genus *Scorpidium* the author excludes the northern *H. badium* Hartm. in spite of its forked leaf-nerves, making it the type of the new genus *Loeskypnum* and giving it the name *L. badium* (Hartm.). The European distribution of *Scorpidium turgescens* includes 2 distinct areas, an arctic area extending as far south as Esthonia and Livonia and an alpine area in the mountains of Central Europe. The organs of vegetative reproduction are deciduous apical buds; these break away and renew their growth directly or else give rise to lateral shoots.—A. W. Evans.

1945. PÉTERFI, MARTIN. O formă teratologică la *Catharinaea Haussknechtii* (Jur. et Milde) Broth. [A teratological form of *Catharinaea Haussknechtii*.] *Bull. Soc. Stiințe Cluj* 1: 149-153. 1 fig. 1921.—A teratological form of *Catharinaea Haussknechtii* is described in which the wall of the archegonium, after fertilization, does not show the usual differentiation into vaginule and calyptra but forms merely an elongated tube enclosing the lower half of the seta. At the upper end vestiges of the neck are often to be seen, showing that the tube has actually arisen from the whole of the ventral wall. In this case the archegonium of a moss resembles that of a liverwort in its later development. In connection with the abnormality just described other teratological features make their appearance, the various organs of the sporogonium (for example) failing to attain their usual size. The author designates the abnormality in the archegonium as "archegonio-solenoidie" and states that no similar case has been described in the literature. In his opinion it yields an additional point of evidence that the Hepaticae form an older group than the Musci.—M. Tiesenhausen.

1946. POTIER DE LA VARDE, R. Récoltes bryologiques en Asie Orientale. [Bryological collections in eastern Asia.] *Rev. Bryologique* 49: 28-31. 1 pl. 1922.—The author gives a list of 11 species of mosses collected in 1914 by V. Demange in Tonkin and China, a definite station being given for each species. *Campylopus Demangei* Thér. et P. de la V. from Tonkin and *Entodon punctulatus* Thér. et P. de la V. from China are proposed as new and illustrated, while *Timmiella multiflora* C. M. is reduced to synonymy under *T. rosulata* C. M. The original description of *Pseudo-Leskea Larminatii* Broth. et Par., a rare species of Tonkin, is corrected and supplemented by an account of the capsule.—A. W. Evans.

1947. QUELLE, FERDINAND. Die Organismen-Spezies als Kurve, an den Moosen dargestellt. [The organism-species as a curve, illustrated by the mosses.] *Bryol. Zeitschr.* 1: 115-137. 27 fig. 1918.—The author brings out the fact that the genus-concept in the organic world is something more or less artificial and that the boundaries of a genus are based on arbitrary distinctions. He emphasizes his point by quotations from Limpricht, in which the vague and uncertain differences between many moss genera are brought out. In order to illustrate the relationships of a species to other species he attempts to represent it graphically by a curve, based on definite characters not subject to a personal equation in their interpretation. He demonstrates his method by means of 25 species of hepatics and mosses and 83 bryophytic characters arranged in a definite series. The first 5 characters, which will

give an idea of the others, are the following: (1) the egg to be fertilized arises in an archeogonium on the moss plant and develops into the sporogonium after fertilization; (2) the green pigment is in chlorophyll-plates with pyrenoids; (3) the green pigment is in chlorophyll grains; (4) special cells with oil-bodies are present; (5) all the green cells contain oil-bodies. Taking the characters of the various species into consideration and using a peculiar method of plotting the author is able to construct a distinctive curve for each species, and these curves are represented by the text figures. In an appendix to the paper theoretical discussions are given on alternation of generations in the mosses and on the significance of the peristome.—A. W. Evans.

1948. THÉRIOT, I. *Le problème du Leucobryum candidum*. [The problem of *Leucobryum candidum*.] Bull. Soc. Bot. Genève 13: 217-225. 3 fig. 1921.—According to Paris and Jaeger *Leucobryum brachyphyllum* (Hornsch.) Hpe. is a synonym of *L. candidum* (Brid.) Jaeger, the latter species being based on *Dicranum candidum* Brid. The author first presents evidence to show that *D. candidum* Brid. is antedated by a few months by *D. candidum* Schwaegr., although both date from 1826, and concludes that the species should therefore be called *Leucobryum candidum* (Schwaegr.) Jaeger. He then shows that *L. brachyphyllum* is amply distinct from *L. candidum* and brings out the differential characters separating the 2 species by means of figures and revised descriptions. At the conclusion of his paper he figures and proposes as new another ally of *L. candidum* under the name *L. confusum*. *L. brachyphyllum* and *L. candidum* are apparently confined to Australia and Tasmania, while *L. confusum* is known from Tasmania, New Zealand and New Caledonia.—A. W. Evans.

1949. THÉRIOT, I. *A propos du Leucobryum candidum*. [Regarding *Leucobryum candidum*.] Rev. Bryologique 49: 31, 32. 1922.—The author corrects a statement made in an earlier paper on *Leucobryum candidum* (see preceding entry). He now shows that the name *Dicranum candidum* Brid. dates from 1798, instead of from 1826, and that the citation *L. candidum* (Brid.) Jaeger is therefore correct.—A. W. Evans.

MORPHOLOGY AND TAXONOMY OF FUNGI, LICHENS, BACTERIA, AND MYXOMYCETES

H. M. FITZPATRICK, *Editor*

D. S. WELCH, *Assistant Editor*

FUNGI

1950. ANONYMOUS. *Pathological herbarium notes* 5. 7 p. U. S. Dept. Agric. Bur. Plant Indust. Office Path. Collections: Washington, D. C. 1922.—Accessions for period, April 1-November 1, 1922, include 2,386 specimens. Lists of exsiccati and special collections received are listed, and noteworthy species represented in recent accessions are named.—H. M. Fitzpatrick.

1951. ANDERSON, J. P. *Some Alaska fungi*. Proc. Iowa Acad. Sci. 27: 99-108. 1920.—A list is given of 133 species of parasitic and saprophytic fungi, from *Plasmodiophora* and the bacteria to Fungi Imperfecti. Determinations were made mostly by the U. S. Department of Agriculture at Washington. Host plants (137) are listed alphabetically; the fungi are systematically arranged, with notes on frequency and habitat.—H. S. Conard.

1952. BARTHOLOMEW, ELAM. *Edible mushrooms of Kansas*. Trans. Kansas Acad. Sci. 30: 174-179. 1919/21 [1922].—A popular account is presented of a few species in Kansas, with a plea for greater utilization.—F. C. Gates.

1953. BONAR, LEE. *The life history of Rosellinia Caryae sp. nov. causing a hickory canker and disease*. Phytopathology 12: 381-385. Fig. 1-3. 1922.—A canker of the twigs and

trunks of young trees of *Carya ovata* (Mill.) Koch. not previously reported has been observed near Ann Arbor, Michigan. The cankers are dead sunken areas, varying from small spots less than 1 inch long to areas 3 inches broad and 6 inches long. On twigs the cankers are usually formed about the leaf scar, but sometimes involve the entire twig. In a few cases young trees, 2-3 inches thick, were killed to the ground. On young twigs the cankers invariably showed numerous fungous pycnidia breaking through the dead bark. Some of the cankered twigs, after being washed in mercuric chloride solution, were placed in test tubes containing a little sterile water. After 6 months perithecia with mature ascospores were quite abundant. Cultures from the ascospores and from the pycnosporos produced pycnidia of the same type.—*B. B. Higgins.*

1954. BOSE, S. R. One new species of Polyporaceae and some polypores new to Bengal. *Ann. Mycol.* 19: 129-131. *Pl.* 1-3. 1921.—*Fomes rufalaccatus* is described as new from Junjub, India. *Polyporus inzonensis* Murrill, *Fomes durissimus* Lloyd, and *Trametes fuscella* Lévillé are reported from Calcutta and Bengal.—*H. S. Jackson.*

1955. BUCHNER, P. Zur Kenntniss der Symbiose niederer pflanzlicher Organismen mit Pediculiden. [Symbiotic relations between lower plant organisms and the Pediculidae.] *Biol. Centralbl.* 39: 535-540. 1919.—The author presents results of investigations conducted contemporaneously with, but independent of, Sikora [see Bot. Absts. 12, Entry 1983] in which he shows that the abdominal organ (Magenscheibe) of certain Pediculidae is a mycelium-harboring body homologous with the mycetocyte of Coccids and with similarly functioning structures in other insects [Blattidae, Hymenoptera (*Camponotus*, *Formica*), and certain Coleoptera]. In all these cases a symbiotic relation exists between the insect and fungus mycelium. The author cites Sikora's priority in the announcement of the true nature of these organs (in head lice and others, the Magenscheibe), but has carried researches further in showing manner in which the eggs of the insect become infected with the fungus. A fuller presentation of results is promised.—*William L. Bray.*

1956. DIETEL, P. Kleine Beiträge zur Systematik der Uredineen. [Minor contributions to the taxonomy of Uredinales.] *Ann. Mycol.* 20: 29-33. 1922.—The author calls attention to the catenulate urediniospores of *Melampsora Hypericorum* (DC.) Wint. and the absence of associated pycnia. The species is thought to be heteroecious and is considered to represent an intermediate form between *Coleosporium* and *Melampsora*. *Mesospora* is proposed as a new genus with this species as the type.—*Tranzschelia* Arth. is accepted as a valid genus on morphological grounds, but the author takes exception to *Lipospora* Arth. and *Polythelis* Arth., -opsis and micro-forms of similar type, on the ground that to accept genera on a life history basis results in placing in different genera species which are obviously closely related. *Tranzschelia Pruni-spinosae* (Pers.) is proposed as a new combination to replace *T. punctatum* (Pers.) Arth. *Lipospora tucsonensis*, *Polythelis fusca*, *P. Pulsatillae* and *P. Thalictri* are transferred to *Tranzschelia*.—The relationship of *Ochropsora* is discussed. Biological evidence is presented which indicates a relationship between *Ochropsora* and *Tranzschelia*. The latter is considered to belong to the sub-family Phragmidatae and it is suggested that the 2 genera may have arisen from a closely related form but show divergent development, especially in the telial stage.—*H. S. Jackson.*

1957. ESSIG, FREDERICK MONROE. The morphology, development, and economic aspects of *Schizophyllum commune* Fries. *Univ. California Publ. Bot.* 7: 447-498. *Pl.* 51-61. 1922.—In summarizing the morphology and development of *Schizophyllum* it may be said that: (1) The sporophores vary greatly as to form and shape. (2) The segments of the mycelium and sporophores, and spores are regularly binucleate. (3) The fungus develops its sporophores as does no other member of the Hymenomycetes so far studied, the hymenium primordium arising in an apical cavity. (4) The "gills" arise upon the surface of an apical depression due to tensions set up by unequal rates of growth. (5) The "lamellae" are such by analogy only, being the edges of smooth hymenial areas, and therefore *Schizophyllum* belongs in the

family Thelephoraceae.—As regards the economic aspects of *Schizophyllum*, it has been shown that: (a) Members of this genus are found throughout the tropical and temperate zones of the world. (b) They live upon a great number of woody dicots, monocots and gymnosperms. (c) The fungus possesses unusual vitality. (d) The mycelium is found only in small amount in infected wood. (e) It can grow upon fresh wood, and, under very favorable conditions, living wood. (f) Natural infection takes place through some injured or weakened part of the tree. (g) The fungus is usually associated with other parasitic fungi, which probably do most of the damage attributed to *Schizophyllum* but escape attention due to the longer time necessary for them to produce fruit-bodies.—W. A. Setchell.

1958. FONTOYNONT, M., et PAX SALVAT. Lésions mycosiques dues au *Saccharomyces granulatus* observées à Tananarive (Madagascar). Leur guérison par le bleu de méthylène. [Fungous lesions due to *Saccharomyces granulatus* observed at Tananarive, Madagascar. Their cure by means of methylene blue.] Bull. Soc. Path. Exotique 15: 53-59. Pl. I. 1922.—Lesions produced on various parts of the body of a native woman were found to be caused by *Saccharomyces granulatus*. The macroscopic and microscopic details of the organism are not dealt with. The reader is referred to a paper by Vuillemin and Legrain [Arch. Parasitol. 1900] for this information. The authors deal mainly with the symptoms of the disease and its treatment with methylene blue.—G. H. Godfrey.

1959. HEDGCOCK, GEORGE G., and N. REX HUNT. Notes on some species of *Coleosporium*.—II. Mycologia 14: 297-310. Pl. 22-23. 1922.—This is principally a record of inoculation experiments with the following: *Coleosporium Ipomoeae*, *C. ribicola*, and *C. Solidaginis*, the last being considered as made up of 2 distinct forms, one occurring on *Solidago* and the other on *Aster*. Successful infections with aeciospores of *Coleosporium Ipomoeae* were obtained on *Ipomoea caroliniana*, *I. lacunosa*, *I. pandurata*, *Pharbitis barbigera*, *P. hederacea*, and *Quamoclit coccinea*. The aecial stage is now known to occur on 6 species of pine of which *Pinus echinata* is "the most common and susceptible host species." *Coleosporium ribicola* has been successfully inoculated on *Pinus edulis*, *P. pinea*, *Grossularia divaricata*, *G. hirtella*, *G. reclinata*, *G. inermis*, *G. innominata*, *G. missouriensis*, *Ribes americanum*, *R. aureum*, *R. fasciculatum*, *R. inebrians*, *R. nigrum*, *R. odoratum*, and *R. vulgare*. *Coleosporium Solidaginis* has been found occurring naturally on about 60 species of *Solidago* and is now reported on the following new hosts: *S. amplexicaulis*, *S. austrina*, *S. bootii*, *S. brachyphylla*, *S. celtidifolia*, *S. chandonnetii*, *S. Chapmanii*, *S. concinna*, *S. Curtissii*, *S. decumbens*, *S. Drummondii*, *S. erecta*, *S. fistulosa*, *S. glomerata*, *S. hispida*, *S. lancifolia*, *S. odora*, *S. petiolaris*, *S. pinensis*, *S. pinetorum*, *S. pulverulenta*, *S. Purshii*, *S. rigida*, *S. rigidiuscula*, *S. speciosa*, *S. stricta*, *S. tortifolia*, *S. unigulata*, and *S. vaseyii*. The *Coleosporium* occurring on *Aster* "is apparently distinct from *C. Solidaginis*." It is known to occur on at least 60 species and is now reported for the first time on the following: *Aster acuminatus*, *A. concinnus*, *A. corrigiatus*, *A. hirsuticaulis*, *A. junceus*, *A. lowrieanus*, *A. oblongifolius*, *A. patulus*, *A. Pringlei*, *A. schistosus*, *A. spectabilis*, *A. tenuicaulis*, *A. Fremontii*, *A. frondosus*, and *A. viscosum*. The *Solidago* form of *Coleosporium Solidaginis* has been successfully inoculated on *Pinus caribaea*, *P. Coulteri*, *P. echinata*, *P. nigra-austriaca*, *P. radiata*, *P. rigida*, *P. scopulorum*, and *P. taeda*.—H. R. Rosen.

1960. ITO, S. A preliminary report on the Japanese species of *Uromyces*. Ann. Mycol. 20: 81-85. 1922.—A list of 56 Japanese species of *Uromyces* is given with synonymy. Eight species new to the flora of Japan are included. *Uromyces Viciae-unijugae* on *Vicia unijuga* Ait. is described as a new species. *U. mercurialis* P. Henn. on *M. leiocarpa* S. & Z. is redescribed.—H. S. Jackson.

1961. IYENGAR, M. O. PARTHASARATHY, and M. J. NARASIMHAN. A new species of *Schizonella*. Phytopathology 12: 435-438. Fig. 1-4. 1922.—A fungus, which is here described as *Schizonella Colemani* n. sp., was found producing a witches broom on *Vitis quadrangularis* Wall.—B. B. Higgins.

1962. KEISSLER, K. *Mykologische Mitteilungen*. [Mycological contributions.] Ann. Naturhist. Mus. Wien 35: 1-35. 1922.—This is the 1st of a series of papers in which new forms are to be described and critical revisions of known groups given. The 1st part of the article is devoted to new forms as follows: *Pleospora* (?) *Ranunculi* on *Ranunculus Huetii* Boiss.; *Thyrsidium botryosporum* Mont. f. *verrucosa* on the bark of *Aleurites moluccana*; *Brachysporium obovatum* (Berk.) Sacc. var. *Clematidis* on dry branches of *Clematis recta* L.; *Mollisia Potentillae* on dry leaves of *Potentilla argentea*; *Rhabdospora Bornmülleri* on sheaths of *Ranunculus Huetii*. In the 2nd part of the article appear the following new combinations: *Phaeosporella Cassiopes* (Rostr.); *Chaetosphaeria Epochnii* (B. & Br.); *Sphaerulina Porothelia* (B. & C.); *Ascophanus minutissimus* Boud. var. *Coemansii* (Boud.); *Plicaria granulosa* var. *Boudieri* (Cke.); *P. olivacea* (Boud.); *Pustularia vesiculosa* var. *Stevensonii* (Ell.); *Helvella atra* var. *murina* (Boud.); *Ascochyta Fraxini* (Desm.); *A. pterophila* (Fautr.); *A. Ulmi* (West.); *Ascochyta ulmella* (Sacc.); *Phomopsis mahoniaecola* (Pass.); *Phyllosticta mahoniae* (Thuem.); *Coniothyrium Campanulae* (Sacc. & Speg.); *C. discincola* (E. & E.); *C. orbicula* (E. & E.); *Botryodiplodia platanicola* (Sacc.). In the discussion of the above forms the names of the following genera also appear: *Didymosphaeria*, *Melanomma*, *Sphaeria*, *Cantharina*, *Glonium*, *Peziza*, *Aleuria*, *Leptopodia*, *Verpa*, *Diplodia*, *Phoma*, *Hendersonia*, *Hyalothyridium*, *Ovularia*, *Papularia*, *Ramularia*. The following are described as new: *Phyllosticta Spegazziniana*, *Diplodia Berkeleyi*, *Hendersonia dianthicola*, *Acetabula vulgaris* f. *pallens*, *A. vulgaris* f. *Barlae* (Boud.).—A. S. Hitchcock.

1963. KRIEGER, LOUIS C. C. A sketch of the history of mycological illustration (higher fungi). *Mycologia* 14: 311-330. Pl. 24-31. 1922.

1964. KURSANOV, L. *Recherches morphologiques et cytologiques sur les Urédinées*. [Morphological and cytological researches on the Uredineae.] Bull. Soc. Nat. Moscou 31: 1-129. Pl. 1-4. 1917 [1922].—This work represents a modification of a dissertation by the same author (in Russian, 1915). It is abridged in part, chapters 6-9 and the historical review of the literature being omitted. It is augmented by new and recent observations by the author. For example he describes among aecidial forms normally binucleate new forms with uninucleate aecidia, *A. leucospermum* on *Anemone ranunculoides*. The uninucleate spores germinate by germ tubes likewise uninucleate but infection experiments gave negative results. The author also describes the development of the aecidial fructification, little known up to the present, of the *Peridermium* type, *Peridermium Strobi*, and of the *Roestelia* type, *Gymnosporangium juniperinum*. He describes the development of *Puccinia gageae*, *Uredo Pirolae*, etc.—The conclusions arrived at in this work are in general the same as those in the Russian publication, viz.: (1) Among the different types of aecidial fructifications the aecidium is the primitive type and the caecoma, of more primitive structure, is the result of a regressive evolution. (2) The aecidial fructifications and the primary sori of short cycled rusts are homologous. (3) The contemporaneous short cycled rusts are regressive but not primitive. (4) The "sexual process" in the Uredineae is not a fertilization but apogamy. (5) The initial forms for the further evolution of the rusts belong to the type *Endo-Uredinalis* (Barclay-Grove hypothesis) and are similar to but not identical with *Endophyllum*.—S. Satin.

1965. Лебедева, Л. А. [LEBEDIEVA, L. A.]. *Микофенологическія наблюденія въ Паркѣи Оранжерейхъ Главнаго Ботаническаго Сада*. [Mycophenological observations in the park and greenhouses of the Botanical Garden of Petrograd.] *Ботаническіе Матеріалы Института Споровыхъ Растеній Главнаго Ботаническаго Сада Въ петроградѣ* [Notulae Systematicae Inst. Crypt. Hort. Bot. Petropolitani] 1: 62. 1922.—The author has undertaken the work of collecting and studying from the morphological, physiological, and phenological points of view the fungi growing in the Botanical Garden of Petrograd. It is to be expected that the mycological flora of such a garden will show a great variety of forms, considering the great number of imported plants and the special conditions in the greenhouses. Five species are enumerated and several observations concerning them are given. The species *Sphaeropsis suspecta* Vestregren, *Phoma thallina* Sacc., and *Cytospora Corni* West, were found in the open

on branches of *Cornus sanguinea*. *Phoma thallina* [not *thalina* as written by the author] is considered as a parasite producing the same symptoms as *Sphaeropsis suspecta*. *Gloeosporium Cattleyae* Sacc. was found in the greenhouse on leaves of orchids (*Cattleya*, *Laelia*, *Lycaste*); the 2 last-named are new hosts for this species. The development of this fungus ceases during the winter and begins again in the spring. *Gloeosporium elasticae* Cooke has been found in the same greenhouse on *Ficus* sp.—A. Jacewski.

1966. Лебедева, Л. А. [LEBEDIEVA, L. A.] О новых Видѣхъ Грибовъ, Собранныхъ Въ Ставропольской Губ. Въ 1916. Матеріалы по обследованію Микологическому Россіи. [New species of fungi from North Caucasus. 1916. Materials for mycological investigations in Russia.] Vol. V, No. 3. Botanical Garden, Petrograd, 1921.—Twelve parasitic or saprophytic micro-fungi hitherto undescribed are enumerated: (1) *Stigmatea Scabiosae* on leaves of *Scabiosa ucrainica*; (2) *Pleosphaerulina Lini* on leaves and stems of *Linum perenne*; (3) *Pleosphaerulina Euphorbiae* on living leaves of an *Euphorbia*; (4) *Mycosphaerella glycyrrhizae* on dead leaves of *Glycyrrhiza glabra*; (5) *Mycosphaerella Phlomidis* on wintered leaves of *Phlomis pungens* infected with *Septoria Phlomidis* Bond. & Lebedieva, which is very probably its pycnidial stage; (6) *Dothidella Thalictri* on dead leaves of *Thalictrum minus*; (7) *Hendersonia Tragopogonis* on dry stems of *Tragopogon major*; (8) *Hendersonia Zygophylli* on dead leaves of *Zygophyllum Fabago*; (9) *Septoria Cucubali* on living leaves of *Cucubalus baccifer*; (10) *Naemospora Rubi* on dead stems of *Rubus idaeus*. (Very probably this is a synonym of *Cytospora Rubi* Schweinitz on the same host cited in North America, but with a very incomplete description. In Europe there is another *Cytospora* on *Rubus idaeus*, *Cytospora ambiens* Sacc., but with quite different stylospores.) (11) *Ramularia Lini* on living leaves and stems of *Linum perenne*; (12) *Ramularia Lithospermi* on living leaves of *Lithospermum officinale*. For all the species complete Latin diagnoses are given.—A. Jacewski.

1967. LUPO, PATSY. Stroma and formation of perithecia in *Hypoxylon*. Bot. Gaz. 73: 486-495. Pl. 18. 1922.—Material from Ohio of *H. coccineum* was studied. The stroma shows 4 distinct regions. Its firm structure is "gained by many mechanical devices for support, such as tubular extensions from cells, branching and intertwining of hyphae and special articulation surfaces." The hyphae are differentiated into 3 types from the time of their emergence from the substratum; those that form the major part of the stroma, those that form the perithecia and Woronin hyphae, and those that form the superficial layers and probably the conidiophores. The cells of the hyphae are originally binucleate, but may become multinucleate. The formation of the perithecia is initiated by the massing of the hyphae into a circular knot, within the center of which the Woronin hyphae differentiate. The ascogonia develop from the cells of the Woronin hyphae by rounding out, partially separating from each other, and increasing in size. The ascogonia do not drop to the bottom of the perithecium in the older stages but come to lie comparatively closer to the bottom by an expansion of the perithecial wall toward the periphery of the stroma. The nuclear program within the ascogonia is one of few divisions and great increase in size, up to the stage where the ascogonia are well rounded out, and then of rapid division without the maintenance of size. The ascogonium buds out protuberances that are the beginnings of the ascogenous hyphae.—B. W. Wells.

1968. MARTIN, G. W. Morphology and cytology of fungi. [Rev. of: GWYNNE-VAUGHAN, DAME HELEN. Fungi. Ascomycetes, Ustilaginales, Uredinales. xi + 232, 196 fig. Cambridge, 1922 (see Bot. Absts. 11, Entry 4253).] Bot. Gaz. 74: 114-115. 1922.—A few details are criticized by the reviewer. He thinks the author's implication that the phenomenon of 2 nuclear fusions is the normal situation in Ascomycetes is premature. Further, the author's interpretation of clamp connections as structures which have no significance other than to facilitate the passage of food or simply as a vegetative phenomenon is criticized as a statement which will need revision. The reviewer argues against changing the current notion of the basidium in the Uredinales, which the author apparently does when she regards the teleutospore cell as involved in the basidium. A final general commendatory statement is made in which the reviewer states that the author "has performed an invaluable service in

collating this work and presenting it so clearly and concisely. The book is a necessity for the reference shelf of every laboratory where mycology is taught." [See also Bot. Absts. 11, Entry 4247.]-B. W. Wells.

1969. MOREAU, FERNAND. *Le mycélium à boucles chez les Ascomycètes.* [The mycelium with clamp connections in the Ascomycetes.] *Compt. Rend. Acad. Sci. Paris* 174: 1072-1074. 1922.—The occurrence of clamp connections on the sides of hyphae at the transverse walls, which is generally considered to be a characteristic of Basidiomycetes, is now found to exist in the Ascomycetes. The hyphae of *Parmelia Acetabulum*, a lichen, are described in this connection. The clamps are shown to have a direct relation to ascus formation, and to be formed on binucleate cells only. It is suggested that this presents evidence as to the closer relationship of the Ascomycetes and Basidiomycetes.—C. H. Farr.

1970. MURRILL, WILLIAM A. *Index to illustrations of fungi, XXIII-XXXIII.* *Mycologia* 14: 332-334. 1922.—This is an index to the illustrations of higher fungi published by the writer in *Mycologia* since 1916.—H. R. Rosen.

1971. Нагорный, Л. И. N[AGORNY, P. I.] *Материалы Для Головных Кавказа.* [Contribution to the knowledge of the Ustilaginales of the Caucasus.] *Вѣстникъ Тифлискаго Сада Тифлисъ* [Bot. Gard. Tiflis Bull.] 51. 1920.—Dr. Nagorny, for several years chief of the mycological laboratory of the plant disease station at Stavropol in North Caucasus, went during the war to Tiflis as chief of the Caucasian bureau of plant diseases, and pursued there his mycological work, one of the results being here published. He gives an enumeration of 25 smuts of the Caucasus, with indications of their habitat and distribution and with critical remarks; most of the enumerated species are common, but some of them are considered as rare. One of these, *Entyloma Thalictri* Schröter described from Silesia on *Thalictrum minus*, does not seem to be very common throughout Europe, having been found subsequently only in Switzerland by Schellenberg on the same host. In North America the species seems to be rather common, and according to Clinton occurs on different species of *Thalictrum*. In Russia it is reported from different localities in European provinces (Smolensk, Orel, Kursk, Tambov) and also in Siberia (Altai), not only on *T. minus* but also on *T. aquilegifolium*. It has been distributed in 2 Russian exsiccatae (Transchel & Seriebriannikov, *Mycotheca Rossica* No. 255, and Buchholtz, *Herb. of Russian Fungi* No. 615). Nagorny indicates it for the Caucasus on *T. minus* and on *T. sp.* The species is decidedly more widely distributed in western Europe, —another example of the great similarity of the North American and Russian mycological floras that have their connection in Siberia. Nagorny presents a new species, *Tilletia Narduri* on *Nardurus sp.*, collected in 1914 by G. Woronow, in Eriwan. [I may mention that specimens of this species were sent to me by Mr. Woronow, and in examining them I came to the conclusion it was a new species of *Tilletia* and named it *T. Narduri*, but as I was neither able to publish nor to correspond with Woronow, my name became a *nomen nudum*, and Nagorny now has full claim to priority. I would not mention a detail of such small importance but for the fact that Nagorny reports his *Tilletia Narduri* on *Nardurus sp.* In my specimens the label written by Woronow himself mentions *Nardurus persica* as the host plant. In 1914 Mr. Sigri-anski, assistant of botany at Voroneje, found in the province of Voroneje a new *Tilletia* on *Lepturus panonicus* and labelled it *Tilletia Lepturi* Sigr. This species is morphologically very near and perhaps identical with *T. Narduri*.]—A. Jacewski.

1972. ОЛЬ, И. А. [OHL, I. A.] *Новый грибокъ, паразитирующий на коробочкахъ мха* *Polytrichum gracile* Dicks. [A new fungus parasite in the capsules of the moss *Polytrichum gracile*.] *Ботанические Материалы Института Словесныхъ Главнаго Ботаническаго Сада.* [Notulae Systematicae Inst. Crypt. Hort. Bot. Petropolitani] 1: 46. 1922.—A new species of *Stagonospora*, occurring in the capsules of *Polytrichum gracile* collected by W. L. Komarov in the summer of 1913 in South-Oussuri (oriental Siberia) is described. It is very different from the *Stagonospora Ravii* (Ellis) Saccardo, known in North America on *Polytrichum formosum*, the stylospores being $37.5-44.5 \times 6.5-7.5 \mu$ and 5-7 septate. A very thorough description

is given in Russian accompanied by a briefer Latin diagnosis. The species is named *Staganospora Komarowii*.—A. Jacewski.

1973. ОЛЬ, И. А. [OHL, I. A.] *Phyllosticta Semeles* Ohl nov. sp. Новый паразитъ живыхъ листьевъ *Semele androgyna* Kunth. [*Phyllosticta Semeles*, a new parasite on living leaves of *Semele Androgyna* Kunth.] Ботанические Материалы Института Словесныхъ Растений Главнаго Ботаническаго Сада въ Петроградѣ. [Notulae Systematicae Inst. Crypt. Hort. Bot. Petropolitani] 1: 60. 1922.—A description and Latin diagnosis are given of a new species of *Phyllosticta* on living leaves of *Semele androgyna*. Numerous whitish spots limited by a red border and containing many pycnidia are developed on the upper surface of the leaves. The stylospores are ellipsoidal, hyaline, $3.5-5 \times 1.5-2.5 \mu$. The only other fungus known on this host is *Ascochyta Semeles* Saccardo, producing very similar spots and identical pycnidia, but with uniseptate, pale olive, fusiform stylospores measuring $8-9 \times 3 \mu$. Considering the similarity of *Ascochyta Semeles* and *Phyllosticta Semeles* the author is inclined to regard these forms as stages of 1 species, and will continue his observations in order to settle the question.—A. Jacewski.

1974. PATTERSON, FLORA W., W. W. DIEHL, and EDITH K. CASH. A list of fungi (Ustilaginales and Uredinales) prepared for exchange. U. S. Dept. Agric. Dept. Circ. 195. 50 p. 1922.—The list comprises 950 numbers.—L. R. Hesler.

1975. PETERSEN, SEVERIN. Agaricaceer iagttagne i Omegnen of Sorø i Juli Maaned 1918-19-20. [Agaricaceae collected in the vicinity of Sorø during the month of July 1918, 1919, 1920.] Bot. Tidskr. 37: 312-315. 1922.—The month of July offers favorable conditions in the vicinity of Sorø for the development of Agaricaceae. For the 3 years Petersen made daily collections. He lists these as he found them from day to day and later makes a systematic classification.—A. L. Bakke.

1976. PETRAK, F. Beiträge zur Pilzflora von Albanien und Bosnien. [Contribution to the fungus flora of Albania and Bosnia.] Ann. Mycol. 20: 1-28. 1922.—About 225 miscellaneous fungi collected in 1918 by the author are enumerated with occasional notes and descriptions. The following species are described as new: *Diaporthe Psoraleae-bituminosae* on stems of *Psoralea bituminosa*; *Lophodermium iridicolum* on decaying leaves of *Iris* sp.; *Cytospora bosniaca* on twigs of *Rosa* sp.; *Diplodia cynanchina*, *Macrophoma cynanchina*, and *Phomopsis cynanchina* on stems of *Cynanchum acutum*; *Microdiplodia Calamagrostidis* on leaves of *Calamagrostis* sp.; *Phoma albanica* on *Spartium junceum*; *Phyllosticta Inulae-viscosae* on leaves of *Inula viscosa*; *Phyllosticta Staticis* on leaves of *Statice* sp.; *Silerophoma confusa* on twigs of *Buxus sempervirens*; *Septoria albanica* on leaves of *Brachypodium silvaticum*; *Staganospora albanica* on leaves of *Brachypodium silvaticum*; *S. calamagrosticola* on leaves of *Calamagrostis* sp.—H. S. Jackson.

1977. PETRAK, F. Beiträge zur Pilzflora von Mähren und Osterr.—Schlesien. V. [Contribution to the fungus flora of Moravia and Austrian Silesia.] Ann. Mycol. 19: 274-295. 1921.—The article consists of a list, with occasional notes and descriptions, of about 220 fungi, chiefly Uredinales, Ascomycetes, and Fungi Imperfecti. The following species are described as new: *Mycosphaerella eupatoriicola* on stems of *Eupatorium cannabinum*; *Ascochyta lupinicola* on *Lupinus* sp.; *Ascochyta Asparagina* on stems of *Asparagus officinalis*; *A. moravica* on stems of *Centaurea scabiosa*; *Dendrophoma emericola* on twigs of *Coronilla emerus*; *Diplodia Genistae-tinctoriae* on *Genista tinctoria*; *Microdiplodia cornicola* on twigs of *Cornus sanguinea*; *M. evonymella* on *Evonymus europaea*; *M. quercicola* on *Quercus* sp.; *M. Rhamni* on *Rhamnus cathartica*; *M. ribicola* on *Ribes rubrum*; *Phoma Genista-tinctoriae* on *Genista tinctoria*; *P. Ribis-grossulariae* on *Ribes grossularia*; *Rhabdospora hranicensis* on stems of *Leucanthemum vulgare*; *Septoria torilicola* on *Torilis anthriscus*.—H. S. Jackson.

1978. REA, CARLETON. *British Basidiomycetae*. *Demy 8 vo.*, xii + 800 p. Cambridge Univ. Press: London, 1922.—This is a handbook to the larger British fungi, published under the auspices of the British Mycological Society. The work is based chiefly on the system set forth by N. Patouillard in his *Essai Taxonomique sur les Familles et les Genres des Hyménomycètes*, published in 1900.—*D. S. Welch*.

1979. Сатина, Софія. [SATIN, SOPHIE.] *Исторія розвитку перитеція Nectria Peziza (Tode.)* [Development of the perithecia of *Nectria Peziza* (Tode.)] *Журнал Русского Ботанического Общества* [Jour. Russian Bot. Soc.] 2: 30-45. *Fig. A-B, 1-19*. 1917. [Printed in 1919 in Russian with a French résumé].—A spiral, multicellular ascogonium is developed; an antheridium is absent. Division of nuclei in the cells of the ascogonium occurs and mitotic figures are pictured. The writer holds the view of Claussen with reference to a fusion of nuclei in the ascogonium.—*H. M. Fitzpatrick*.

1980. Сатина, Софія. [SATIN, SOPHIE.] *Оплодотвореніє ч історія розвитку Cubonia brachyasca Sacc.* [Fertilization and life-history of *Cubonia brachyasca* Sacc.] *Журнал Русского Ботанического Общества*. [Jour. Russian Bot. Soc.] 4: 77-94. 2 pl. 1918/1919 [1921].—*Cubonia brachyasca* Sacc., a very rare coprophilous fungus belonging to the Ascobolaceae, was found by the author on horse dung sent from Siberia to the Botanical Laboratory of the Women's University of Moscow. *Cubonia* was cultivated on dung agar, and usually numerous apothecia reached maturity on cultures 4-5 days old. The presence of bacteria was necessary for their development. Changing the conditions of light, temperature, and medium had no influence on the fructification. The ascocarp originates from a pair of morphologically distinct sex cells and fertilization takes place. The spirally coiled ascogonium is composed of 3 parts: (a) the 1-celled trichogyne, bent like a hook; (b) the oogonium, easily distinguished by its large dimensions and dense contents; and (c) the several-celled stalk. The many-celled antheridium twists around the ascogonium and its terminal cell fuses with the apex of the trichogyne. After fertilization has taken place these cells become empty and degenerate. The fertilized oogonium enlarges and soon a considerable number of ascogenous hyphae grow out and form asci. The poorly developed peridium is formed from hyphal branches which originate from the cells of the stalk; it does not usually develop before the ascogenous hyphae appear. The process of fertilization and the greater part of the gradual development of the ascocarp can thus be observed in the living state. All the cells of *Cubonia* are multinucleate. There is no evident difference between the male and female nuclei. No fusion occurs in the oogonium, the fusion in the ascus hook being the only one in the life-cycle.—*Sophie Satin*.

1981. Сатина, Софія. [SATIN, SOPHIE.] *Къ історіі розвитку Phacidium repandum*. [The life-history of *Phacidium repandum*.] *Журнал Русского Ботанического Общества*. [Jour. Russian Bot. Soc.] 4: 95-102. 1 pl. 1918/1919 [1921].—The apothecia and pyrenidia of this parasitic fungus develop on living leaves of *Galium rubiginoides*; both appear in early spring but the pyrenidia predominate in the 1st part of summer, the apothecia in the 2nd. They develop independently below the stomata. *Phacidium repandum* is apogamous; there are no male cells. The development progresses as follows: Several vegetative hyphae begin to grow strongly under a stomate and form a stromatic tissue. Soon several ascogonia are differentiated in this more or less well-developed tissue. Each of these consists of a row of coiled cells filled with dense protoplasm. The terminal cells of these ascogonia pass through the stomate; they are considered as functionless trichogynes, 6-8 often passing through a single stomate. The cells of the ascogonium bud and form ascogenous hyphae with asci. Part of the stromatic tissue forms the peridium. The fruit-body increasing in size reaches maturity, ruptures the epidermis of the host plant, and appears on the surface of the leaf. The cytology has not been investigated. The cells of the ascogonium are uninucleate.—*Sophie Satin*.

1982. SCHINZ, HANS. *Der Pilzmarkt der Stadt Zurich der Jahre 1918 und 1919 im Lichte der städtischen Kontrolle*. [The mushroom market of the city of Zurich in the years 1918 and

1919 in the light of city supervision.] Vierteljahrsschr. Naturf. Ges. Zurich 65: 530-544. 1920. The author gives lists of mushrooms offered for sale and the approximate quantities sold of each species. The characters by which wholesome species may be segregated rapidly from poisonous and disagreeable species are briefly considered.—*John H. Schaffner*.

1983. SIKORA, H. Voläufige Mitteilung über Mycetome bei Pediculiden. [Preliminary report upon the occurrence of a mycetome in Pediculidae.] Biol. Centralbl. 39: 287-288. 1919.—The author announces his conclusion that the long recognized "Magenscheibe," or glandlike organ, found in certain Pediculids (head louse, clothes louse, felt louse, and rat louse) is really a fungous filament-harboring organ or mycetome in which at certain stages in the embryonal life of these insects develops an abundance of mycelium of significance in a symbiotic relation. In embryonic stages of the swine louse a homologous organ is also found, which, however, is not seen in the mature louse. The author believes this mycetome to be present in other species of lice and announces early publication of his investigations in full. [See also Bot. Absts. 12, Entry 1955.]—*William L. Bray*.

1984. SYDOW, H. Bemerkungen zu einer Anzahl in letzter Zeit als neu beschriebener Pilze der Philippinen-Inseln. [Observations on some fungi recently described as new from the Philippine Islands.] Ann. Mycol. 20: 66-73. 1922.—Notes are given on 23 recently described fungi, most of which are considered to be identical with previously described forms. A few are redescribed.—*H. S. Jackson*.

1985. SYDOW, H. J. Bornmüller: Plantae Macedoniae. Pilze. [J. Bornmüller: Plants of Macedonia. Fungi.] Ann. Mycol. 19: 243-254. 1921.—A list is given, with occasional notes, of 81 fungi (mostly parasitic) in various groups based on the collections of J. Bornmüller. The following new species are described: *Uromyces Hippocrepidis* on *Hippocrepis ciliata*; *Puccinia Loliana* on *Lolium perenne*; *Coleosporium Asterisci-aquatici* on *Asteriscus aquaticus*; *Aecidium macedonicum* on *Asyneuma limonifolium*.—*H. S. Jackson*.

1986. SYDOW, H. Mycotheca Germanica Fasc. XXIX-XXXVI (No. 1401-1800). Ann. Mycol. 19: 132-144. 1921.—A numerical list is given of the fungi included in the exsiccati. Critical notes are given on 14 of the species included. Descriptions are given for the following new species or varieties: *Mycosphaerella Deutziae* on leaves of *Deutzia Lemonii*; *M. equisetina* on culms of *Equisetum hiemale*; *M. Thelypteridis* on dead fronds of *Aspidium Thelypteris*; *Microthyrium culmigenum* on culms of *Calamagrostis lanceolata*; *Hysterostegiella Typhae* on leaves of *Typha angustifolia*; *Excipula Kriegeriana* on stems of *Sisymbrium strictissimum*; *Helotium herbarum* (Pers.) var *carpogenum*, and *H. stutula* (Pers.) Karst. var. *aesculicarpa* on fruit hulls of *Aesculus Hippocastanum*; *Septoria Glaucis* on leaves of *Glaux maritima*; *Phleospora Ludwigii* on leaves of *Salix repens*; *Oospora marchica* on dead petioles of *Robinia pseudo-acacia*; *Didymaria Matricariae* on leaves and stems of *Matricaria discordea*; *Septoria Matricariae* on leaves of *Matricaria Chamomilla*; *Cercospora Echii* on leaves of *Echium vulgare*. *Stegia Caricis* Pk. is transferred to the genus *Hysteropezizella* and *Leptothyrium asterinum* Berk. & Br. is transferred to *Macrophoma*.—*H. S. Jackson*.

1987. SYDOW, H. Novae fungorum species XVII. [New species of fungi XVII.] Ann. Mycol. 19: 305-309. 1921.—The following new species are described: *Aecidium prolixum* on *Wrightia lanata* from the Philippines; *Meliola guamensis* on *Ochrosia* sp. from Guam; *Nummularia patella* on dead wood from the Philippines; *Cryptosphaeria cubensis* on dead branches of *Acacia Farnesiana* from Cuba; *Didymella Caricis* on dead leaves of *Carex lepidocarpa* from Kurland; *Gibbera aequatoriensis* on leaves of *Cestrum* sp. from Ecuador; *Bombardiastrum javanicum* on dead branches of *Rauwolfia javanica* from Java; *Rosencheldiella Litsea* on leaves of *Litsea glauca* from Japan; *Asterina Balii* on leaves of *Alangium Lamarkii* from India; *A. delicatula* on leaves of *Aegle marmelos* from India; *Phaeociboria brasiliensis* on inflorescence of *Pinus* from Brazil; *Ustilaginoidea borneensis* on heads of *Ischaemum aristatum* from North Borneo. A new genus, *Thyrosema*, of the Microthyriaceae, based on *T. pulchellum* n. sp. on leaves of *Erythroxylon* from Amboina is described and its relationship discussed.—*H. S. Jackson*.

1988. SYDOW, H. The Amboina fungi collected by C. B. Robinson. *Philippine Jour. Sci.* 21: 131-146. 1922.—Seventy species are enumerated, the following being described as new: *Meliola Eugeniae*, *M. amboinensis*, *M. pachychaeta*, *M. Stemonae*, *M. Robinsonii*, *M. megalochaeta*, *M. odontochaeta*, *Diathrypton* (gen. nov.) *amboinense*, *Catacauma microplacum*, *C. Robinsonii*, *Trabutia amboinensis*, *Asterina spectabilis*, *A. venustula*, *A. assimilis*, *Prillieuxina Loranthei* comb. nov. (*Asterinella Loranthei*), *P. microspila*, *P. amboinensis*, *Parasterina melanochetes*, *Calothyrium vile*, *Lembosia Robinsonii*, *Echidnodes xenospila*, *Thyrosoma* (gen. nov.) *pulchellum*, *Byssogene* (gen. nov.) *amboinensis*, and *Asteromella polystigma*.—E. D. Merrill.

1989. SYDOW, H. Über einige wenig bekannte Uredineen aus dem Kew Herbar. [Concerning some little known Uredinaceae from the Kew Herbarium.] *Ann. Mycol.* 20: 54-60. 1922.—The author reports on the result of an examination of the original specimens of 19 species of *Uromyces* and *Puccinia* chiefly named by Berkeley or Cooke. A redescription of each valid species is given. *Uromyces Diploglottidis* Cke. & Mass. is transferred to the genus *Ctenoderma*. Several species are considered synonymous with species previously or subsequently described.—H. S. Jackson.

1990. SYDOW, H. Über einige weitere im südlichen China (Kwangtung-Provinz) gesammelte Pilze. [Concerning some additional fungi collected in southern China.] *Ann. Mycol.* 20: 61-65. 1922.—A report is given of 2 collections of fungi made by E. D. Merrill and C. W. Howard. A total of 31 species is listed. The following new species are described: *Aecidium Raphiolepidis* on *Raphiolepis indica*; *Meliola leptoclada* on *Schefflera octophylla*; *Englerulaster sinensis* on *Ilex ficoidea*; *Melasmia Alni* Syd. on *Alnus* sp.; *Puccinia polystegia* on *Daedalacanthus nervosus*; *Phyllachora pennisetina* on *Pennisetum alopecuroides*, *Cercospora atrides* on *Bridelia monoica*; *C. micromera* on *Sapium sebiferum*. A new genus of Fungi Imperfecti, *Elaeodema* based on *E. Cinnamemi* n. sp. on fruits of *Cinnamomum pedunculatum*, is described.—H. S. Jackson.

1991. VUILLEMIN, PAUL. Relations entre les chlamydospores et les boucles mycéliennes. [The relation between chlamydospores and clamp-connections.] *Compt. Rend. Acad. Sci. Paris* 174: 1148-1149. 1922.—The clamps are formed by a process which is intermediate between exogamy and endogamy. They are homologous to the ascus hooks of the ascomycetes. They are found on the binucleate mycelium which characterizes the diplo-phase of both ascomycetes and basidiomycetes. In some forms, chlamydospores bear the same relation to the asci and basidia as do the clamps. It is believed that the production of clamps is not necessary to the development of asci and basidia. The chlamydospores of *Nyctalis Asterophora* are homologous to the clamps of *N. parasitica*. In like manner the chlamydospores of *Bornetina Corium* are homologous to the clamps of *B. aurea*.—C. H. Farr.

1992. VUILLEMIN, PAUL. Une nouvelle espèce de *Syncephalastrum*; affinités de ce genre. [A new species of *Syncephalastrum*; the affinities of the genus.] *Compt. Rend. Acad. Sci. Paris* 174: 986-988. 1922.—This new species is parasitic on *Rhizopus*. It is concluded that this genus should be classified in the tribe Absideae of the Mucoraceae.—C. H. Farr.

1993. WELLES, C. G. A provisional list of the parasitic fungi of the Philippine Islands. *Philippine Agric. Rev.* 15: 149-202. 1922.—About 958 species in 260 genera are listed, with their recorded hosts. A host index and an index to genera and families are given. No bibliographic references are included.—E. D. Merrill.

1994. WILSON, GUY WEST. Notes in some fungi from Eastern Kansas. *Trans. Kansas Acad. Sci.* 30: 171-174. 1919/21 [1922].—This is an annotated list of 43 species, chiefly from the vicinity of Lawrence.—F. C. Gates.

1995. WILSON, MALCOLM. A new species of *Phomopsis* parasitic on the Douglas fir. Trans. and Proc. Bot. Soc. Edinburgh 28: 47-49. 1920.—*Phomopsis Pseudotsugae*, attacking Douglas fir, *Pseudotsuga taxifolia* (= *Douglasii*), is described. It attacks the leading shoots and also the trunks of young trees and causes their death. It appears to be widely distributed in Scotland.—*Roxana Stinchfield Ferris*.

1996. Воронихинъ, Н. Н. [WORONICHIN, N. N.] Къ флорѣ Рhycomycetes Кавказа. [Contribution to the phycomycetous flora of the Caucasus.] Вѣстникъ Ткъфлискаго Вotаническаго Сада Тифлисъ [Bot. Gard. Tiflis Bull.] 50. 1920.—The Mycological Flora of the Caucasus has been very thoroughly investigated in the last 25 years and mycologically this region is one of the best known in Russia. Not all the groups of fungi have been equally investigated, and the aquatic fungi have been little known. In this pamphlet the author pays special attention to these and has identified 9 species, belonging to the Chytridineae (4), Ancylistineae (4), and Pythiaceae (*Pythium gracile*). *Lagenidium papillosum* Cocc. on *Spirogyra* is reported from Russia for the 1st time, being known previously only from Italy. In *Pythium gracile* oospores, previously unknown in the species, were found in great number; they are spherical, hyaline, smooth, and measure 8-15.8 μ (usually 12.6-14 μ). *Pythium tenue* Gobi, which is similar, has larger oospores and differs in several other points. E. J. Butler described oospores belonging to a form identified by him as *Pythium gracile* [An Account of the Genus *Pythium*. Calcutta, 1907], but their size is somewhat larger (13-24 μ).—A. Jacewski.

1997. Воронихинъ, Н. Н. [WORONICHIN, N. N.] Микологическія замѣтки. I: Нѣкоторые результаты микологическихъ изслѣдованій въ районѣ Воржомъ-лереваль Цхра Цхаро. [Mycological notes. I. Some results of mycological researches in the region Borjome-Tskhratskharo.] Извѣстія Кавказскаго Мчзея Тифлисъ [Bull. Caucasian Mus. Tiflis] 12: 1918.—The author enumerates and describes 25 fungi from different groups, mostly Imperfecti, collected in the alpine and subalpine region near Borjom in the summer of 1916. The majority are rather common species, but some are new for Russia, namely: *Septoria bulgarica* Bub. & Malk., previously known only in Bulgaria on *Cirsium appendiculatum* and found here on *Cirsium obvallatum*; *Septoria Daniloï* Bubak, described from Montenegro on *Geranium lucidum* and found here on *Geranium pallens* with larger stylospores (72-82 \times 2 μ) and pycnidia (170-187 \times 155-187 μ); *Septoria Pyrethri* Bres. & Krieger, known from Germany on *Pyrethrum Parthenium* and discovered here on *Pyrethrum macrophyllum*.—A. Jacewski.

1998. Воронихинъ, Н. Н. [WORONICHIN, N. N.] Новые виды грибовъ съ Кавказа. [New or little known fungi from the Caucasus.] Вotаническіе Матеріалы Института Слоровыхъ Раствній Главнаго Вotаническаго Сада. [Notulae Systematicae Inst. Crypt. Hort. Bot. Petropolitani] 1: 33. 1922.—Latin diagnoses are given of 4 new fungi collected in Transcaucasia. One species, *Elenkinella mirabilis*, represents a new genus belonging to the family Englerulaceae, typical tropical forms characterized by the dehiscence of the perithecia. This new genus is chiefly differentiated from others of the same family by the tri-septate, hyaline spores. The species is peculiar in its habitat, being found in the glands of the leaves of *Verbascum pyramidatum*. The other new species described by the author are rusts: *Puccinia Coronillae* (teleutospores on *Coronilla cappadocica*), *Aecidium Coronillae* (on the same host and associated with the former), *Aecidium Willemetiae* (on leaves of *Willemetia tuberosa*, differing from the aecial stage of *Puccinia Willemetiae* Bubak in the structure of the pseudo-peridia and the difference in size of the spores).—A. Jacewski.

1999. Вороновъ, Ю. Н. [WORONOV, G. N.] Сводъ свѣдѣній о микофлорѣ Кавказа. Часть I. Списокъ грибовъ по сихъ лорѣ извѣстныхъ для кавказа. Юревъ. [Bibliographical index to the Caucasian fungus flora. Part I. Description of Caucasian fungi now known.] 200 p. Yuriev, 1915.—During the last 25 years the Caucasus has been thoroughly investigated by a number of able mycologists (Speschnev, Woronichin, Siemaschko, Woronov, and others) and their studies have been published in a great many different papers. Therefore an index

has been necessary and will be of great aid in further work. The index is similar to the Bibliographical Index of North American Fungi begun by W. G. Farlow, but instead of the alphabetical arrangement the classification of Engler und Prantl in *Die Pflanzenfamilien* has been followed. In this 1st part there are enumerated 445 genera with 1734 [since 1915 this number has considerably increased, and one of our best mycologists, living now in Tiflis, N. N. Woronichin, estimates in 1920 the approximate number of Caucasian fungi equal to 3000, nearly 50 per cent of the whole Russian mycological flora.—*Collaborator's Note.*] species found in Caucasus (inclusive of the Fungi Imperfecti). This is a rather large number considering the fact that for all of Russia the actually known species are estimated at approximately 6000 (inclusive of the Myxomycetes and Fungi Imperfecti) in 878 genera. This rather large number is explained by the great climatic differences present. In the alpine region of the Caucasian chain northern and subpolar species are found, while near the Black Sea, at Suchum and Batum it is not rare to detect typical subtropical forms (*Pseudocolus*, *Asterina*). The 2nd part of this work will contain a bibliographical catalogue. It is intended also to give a list of the herbaria in which Caucasian fungi are to be found, a complete list of the collectors, an alphabetical list of the fungi and of the different hosts, and a history of Caucasian mycology.—A. Jacewski.

2000. ZELLER, S. M. Morphological differences between *Nectria galligena* Bres. and *N. coccinea* (ditissima). [Abstract.] *Phytopathology* 12: 442. 1922.

LICHENS

2001. BATTEN, LILY. Note on the occurrence of *Arthopyrenia foveolata* at Plymouth. *Jour. Marine Biol. Assoc. United Kingdom* 12: 557. 1921.—*Arthopyrenia foveolata* is a crustaceous calcareous lichen occurring at Plymouth, England, in large patches on rocks both above and below the high-water mark and also on limpets and barnacles. It was first found on the coast of Yorkshire in 1901 and has since been collected at various places on the coast of Ireland. The algal element is filamentous and yellowish and belongs to the genus *Trentepohlia*. The perithecia are minute.—Marshall A. Howe.

2002. FINK, BRUCE. Lichens. [Rev. SMITH, ANNIE L. Lichens. xxvii + 404 p., 165 fig. Cambridge Univ. Press: England. 1921 (see Bot. Absts. 11, Entry 3459).] *Bot. Gaz.* 74: 115-117. 1922.—Though recognizing many valuable features of the work, the reviewer finds it necessary to object vigorously to the maintenance in it of the old idea that "lichens are not plants, but yet in some mysterious way are plants." He believes it to be very unfortunate that the author could not have followed the modern and logical interpretation that lichens are fungi using algae as hosts. [See also Bot. Absts. 10, Entry 629; 11, Entries 274S, 2749, 3424.]—B. W. Wells.

2003. HÜEG, OVE. Die norwegischen *Nephroma*-Arten. [The Norwegian species of *Nephroma*.] *Nyt Mag. Naturvidenskab.* 60: 85-97. Pl. 1, fig. 1-3. 1922.—A key to the Norwegian species of *Nephroma* and a survey of their occurrence and distribution are given. Five species belong to the Norwegian flora.—The anatomical features of the genus are described. The "papillae" on the under side of *N. resupinatum* are always present in this species, but never in the other European species of the genus. The anatomy presents considerable similarity to the cyphellae in *Sticta*, and the physiological function must also be the same, corresponding to the stomata of the higher plants.—The tomentum on the under side of the thallus is composed of branched hairs, from which curious spherical cells are set free. The pycnids in all species are described, located on the under side of the thallus in *Nephroma expallidum*.—K. Münster Ström.

2004. MELLOR, ETHEL. Les lichens vitricoles et la détérioration des vitraux d'église. [Lichens on glass and the deterioration of church windows.] *Rev. Gen. Bot.* 34: 280-285, 336-345. 1922.—The flora of glassware is usually made up of crustaceous lichens which exist for the most part on the exterior surface; a notable exception is *Biatorina erysiboides*,

which exists only on the interior surface. The factors influencing the vitricolous lichens in their selection are: (1) the surface of the glass, whether it be smooth and shining or corroded; (2) such agents as wind, rain, and sun; (3) the number of species which grow in the neighborhood; (4) diffuse light and tainted air. *Caloplaca vitricola* with its variety *violacea* is described as new. The study on corrosion of glass furnished the following conclusions: (a) The immediate cause of corrosion is the mechanical action exerted by the vitricolous lichens on the surface of glass altered chemically; (b) the chemical alteration of glass is accelerated by the presence of vitricolous lichens; (c) the glass colored yellow by silver resists corrosion for a long time; (d) an annual cleaning of the glass is sufficient to protect it against the invasion of vitricolous lichens, for the germination of spores and growth of thalli is very slow. In addition, the mechanical action on glass is at a minimum during the first months of development. The lead frame should be kept in a good state of preservation.—The action of lichens on rocks particularly slate and feldspar was also studied. The action was found to be much the same as on glass. By increasing the rapidity of weathering the lichens play an important role in the beginning of the change from rock to soil.—*J. C. Gilman.*

BACTERIA

2005. DUFRENOY, J., et R. MOLINERY. Resultats de recherches d'hydrobiologie thermale poursuivies à Bareges et à Luchon. [Results of investigations of the biology of thermal springs in Bareges and Luchon.] Jour. Med. Bordeaux. 1922.—Three physiological groups of microorganisms are considered: (1) those which secrete peptic zooglaeae forming "Barègine" deposits; (2) Thiobacteriaceae, chiefly *Thiothrix*; (3) Ferrobacteriaceae, *Clonothrix*, *Leptothrix*, and *Sederocapsa*.—*J. Dufrénoy.*

2006. JENNISON, H. M. Potato blackleg with special reference to the etiological agent. [Abstract.] Phytopathology 12: 444. 1922.

2007. LÖHNIS, F. Studies upon the life cycles of the bacteria. I. Review of the literature 1838-1918. Mem. Nation. Acad. Sci. [U.S.A.] 16: 1-335. Pl. A-S, 1-23. 1921.—In the light of the results obtained by the author and N. R. Smith in studies of the *Azotobacter* group it was thought advisable to review all the important literature in the hope of finding further confirmation of amorphic or symplasmic stages and different types of regeneration of bacteria. Though the author feels that the existing classification does not truly express natural relationships, it is followed for convenience. The review of the literature, which is discussed more from a morphological than from a physiological standpoint, is divided into these headings: (1) different cell forms; (2) reproductive organs (gonidia, regenerative bodies, spores, microcysts); (3) formation of symplasm and regeneration of cells; (4) conjunction; (5) methods. A bibliography of 133 pages is given.—*Roxana Stinchfield Ferris.*

PALEOBOTANY AND EVOLUTIONARY HISTORY

E. W. BERRY, *Editor*

(See also in this issue Entries 1817, 2125, 2126, 2206)

2008. ANONYMOUS. A forest under the city of Washington. Science 56: 529-530. 1922.—An excavation disclosed a layer of black swamp muck containing large quantities of well preserved tree trunks and large stumps. The trees were bald cypress and lived in the latter part of the Great Ice Age.—*C. J. Lyon.*

2009. ANONYMOUS. The Devonian forest at Gilboa, N. Y. Science 56: 565. 1922.—Work of excavation by the New York Board of Water Supply at Gilboa, New York, has brought to light many large specimens of the earliest known trees. These trees, though known for many years, have heretofore disclosed no definite relationships. WINIFRED GOLDRING finds evidence of their being seed ferns (Pteridospermophyta) much like *Lyginopteris* but simpler in organization.—*C. J. Lyon.*

2010. CARPENTIER, ALFRED. Sur les conifères et les fougères du Wealdien de Féron-Glageon. [On the conifers and ferns of the Wealdian of Féron-Glageon.] Compt. Rend. Acad. Sci. Paris 174: 1121-1124. 1922.—The Wealden flora of northern France contains numerous traces of conifers, ferns, cycadophytes, and Ginkgoales. Descriptions of a number of conifers and ferns are given.—C. H. Farr.

2011. FENTON, CARROLL LANE. The Hackberry stage of the upper Devonian. Amer. Midland Nat. 6: 179-199. Pl. 1, fig. 2. 1920.—The locality of the formation described in the paper is Hackberry Grove Clay Bank in section 35, Portland Township, Cerro Gordo County, Iowa. The author lists the fossils (mainly animal) in each of 3 divisions of the formation. The plant forms are classified as "fucoids" of which "at least two species" are found in the Owen substage, "three or more" in the Spirifer zone, and "several species" in the Striatula zone. None of these plant species are described or named by the author.—Sister M. Ellen.

2012. FLORIN, R. On the geological history of the Sciadopitineae. Sverg. Bot. Tidskr. 162: 260-270. Fig. 2. 1922.—*Sciadopitys*, represented in the existing flora by a single Japanese species, is regarded as an old type. The author finds that the linear leaves with a median furrow, in which the stomata occur and in which the epidermal cell arrangement is less distinctly seriate, afford distinctive features readily recognizable in microscopic preparations of fossil cuticular material. He considers that *S. tertiaria* Menzel, from the German Tertiary, is close to the existing species, and that the fossil genus *Sciadopitytes* of Goeppert is also related to it. To *Sciadopitytes* he refers several species from Greenland which Heer described as *Pinus*, and describes the following new species: *S. Hallei*, *S. scotica*, *S. macrophylla*, and *S. scanica*. In all 12 species of *Sciadopitytes*, ranging in age from Rhaetic to Upper Cretaceous, are enumerated. A fuller discussion is promised in a future publication.—E. W. Berry.

2013. FLORIN, R. Über das Vorkommen von *Sciadopitys* im deutschen Tertiär. [On the occurrence of *Sciadopitys* in the German Tertiary.] Senckenbergia 4: 1-5. Pl. 1. 1922.—The author describes the epidermal characters of specimens from the upper Pliocene of Klärbecken, Frankfurt, and concludes that they represent *Sciadopitys* and are identical with the lower Miocene species *S. tertiaria* Menzel.—E. W. Berry.

2014. FRENTZEN, K. Die Keuperflora Badens. [The Keuper flora of Baden.] Verh. Naturw. Ver. Karlsruhe 28: 1-76. Pl. 1-4. 1919.—This is a revision of the Keuper or upper Triassic flora of this classic region of southwestern Germany; 28 species are described. These include 3 Arthropytes of the genera *Equisetites* and *Neocalamites*; 12 ferns of the genera *Anopteris*, *Pecopteris*, *Sphenopteris*, *Gleichenites*, *Clathropteris*, *Dictyophyllum*, *Chiropteris*, and *Danaeopsis*; 7 Cycadophytes of the genera *Pterophyllum*, *Dioonites*, and *Otozamites*; 2 Ginkgoales of the genus *Baiera*; 2 Coniferophytes of the genera *Voltzia* and *Widdringtonites*; coniferous wood and the uncertain genus *Schizostachyum*, possibly representing the cones of *Neocalamites*.—E. W. Berry.

2015. JOHNSON, T., and J. G. GILMORE. *Libocedrus* and its cone in the Irish Tertiary. Sci. Proc. Roy. Dublin Soc. 17: 66-70. Pl. 4. 1922.—*Libocedrus salicornioides* (Unger) from the bore at Washing Bay, and from the Interbasaltic at Ballypalady, Ireland, is described.—E. W. Berry.

2016. JOHNSON, T., and J. G. GILMORE. The lignite of Washing Bay, Co. Tyrone. Sci. Proc. Roy. Dublin Soc. 17: 59-65. Pl. 3. 1922.—Microscopic study of material from a deep boring shows it to represent the species *Sequoia Coultssiae* Heer, a widespread Tertiary conifer. Much of interest in the comparative anatomy of *Sequoia*, *Athrotaxis*, *Taiwania*, *Taxodiioxylon*, *Taxodium*, and *Cupressinoxylon* comes out of the discussion.—E. W. Berry.

2017. KRÄUSEL, R. Beiträge zur Kenntnis der Kreideflora I. Über einige Kreidepflanzen von Swalmen (Niederlande). [Contributions to knowledge of the Cretaceous flora I. On Cretaceous plants from Swalmen, Holland.] Mededeel. s' Rijks Geol. Dienst A2:

1-40. *Pl. 1-5.* 1922.—The following are identified from between 642-659 m. in a deep bore at Swalmen, Holland: *Didymosaurus comptoniaefolius*, *Araucaria crassifolia*, *Elatocladus elegans*, *Moriconia cyclotoxon*, *Sequoia reichenbachii*, *S. sp.*, *Myrica cretacea*, *M. longifolia* (?), and *M. pseudoquercifolia*, the last being described as new. The epidermal characters of a number of these are described and it is concluded that the geological horizon is the same as the Upper Cretaceous Aachen (Aix-la-Chapelle) sands.—*E. W. Berry.*

2018. SCOTT, D. H. The present position of the theory of descent, in relation to the early history of plants. Rept. British Assoc. Adv. Sci. 1921: 170-186. 1921.—[See Bot. Absts. 11, Entries 502, 521.]

2019. THOMAS, H. H. On a new group of angiospermous fruits from the Middle Jurassic of Yorkshire. [Abstract.] Rept. British Assoc. Adv. Sci. 1921: 452. 1921.

2020. WEBSTER, CLEMENT L. Observations on some marine plants of the Iowa Devonian, with descriptions of new genera and species. Amer. Midland Nat. 6: 286-289. 1920.—Six new species, 5 of which are included in 3 new genera of the upper Devonian or Hackberry group at Bloody Run in Floyd County, Iowa, are described as follows: *Zearamosus elleria* n. gen., n. sp.; *Gracilirectus Hackberryensis* n. gen., n. sp.; *Fruticristatum iowense* n. gen., n. sp., and the new forms *moraense* and *pervetus*; *Buthotrephis thomasia* n. sp.—*Sister M. Ellen.*

DISEASES CAUSED BY FUNGI

2021. B[ERNARD, CH.] Djamoer oepas op Sesbania. [Poison fungus on Sesbania.] De Thee 1: 44-45. 1920.—*Djamoer oepas* (*Corticium Javanicum*) attacks *Sesbania* as it does many legumes under favorable circumstances. A crust of *Capnodium*, growing in the sweet excrement of a cicada (*Lawana*), provided a moist cover which favored the development of the *Corticium* in the serious attack observed.—*Carl Hartley.*

2022. BERNARD, CH., en A. KEUCHENIUS. Bestrijding van wortelziekten. [Control of root diseases.] De Thee 1: 35-41. 1920.—This is a preliminary report of tests with soil disinfectants and amendments against the "split-canker" fungus (*Armillaria*) and the red root fungus (*Poria*) of tea. Plants in the earliest stages of disease were treated. The amounts of the different substances added were, per plant, 8½ l. of 1 per cent carbolic acid; 1½ l. of 10 per cent carbolineum; 8½ l. of wood ashes + an equal quantity of water containing 30 cc. carbolic acid; and air-slaked lime. The carbolic acid treatment proved useless; lime and carbolineum seemed to have some value; ashes with carbolic acid proved disappointing. On another estate the application of 3 and 9 kgm. wood ashes per plant, the former on a large scale, indicated value. In a 3rd locality lime treatment was followed by improvement, and parallel ammonium sulphate treatment by an increase in disease. The tests will be continued. Crude inoculation with *Armillaria* by placing diseased roots and stumps in the soil was successful.—*Carl Hartley.*

2023. CIFERRI, R. Una rara malattia delle foglie del susino. [A rare disease of plum foliage.] Riv. Patol. Veg. 12: 59-64. 1922.—A rare affection of leaves of plum, variety Luther Burbank, was found to be due to a fungus morphologically identical with *Microstroma*

Tonellianum Ferraris. The spores are borne on basidia-like conidiophores crowded closely together inside the epidermis on the under side of the leaf. A part of the literature on the systematic position of the genus *Microstroma* is reviewed.—*F. M. Blodgett*.

2024. DIETRICH, F. O. Über die Erkrankung der Kartoffeln. [Disease in potatoes.] Mitteil. Deutsch. Landw. Ges. 37: 614-616. 1922.—The author discusses the effect of drought and other meteorological conditions on potato diseases and on the yield in Germany, giving especial attention to potato wart. The selection of healthy plants and wide spacing are advised.—*Lillian C. Cash*.

2025. FULTON, H. R. Occurrence of *Thielaviopsis paradoxa* on the cocoanut palm in Florida. Phytopathology 12: 398-399. 1922.—*Thielaviopsis paradoxa* (De Seyne) v. Höhn. was found causing a decay in the trunk of a cocoanut palm (*Cocos nucifera*).—*B. B. Higgins*.

2026. GARRETSEN, A. J. Roetdauw. [Sooty mold.] De Thee 2: 56-57. 1921.—*Hormiscium* sp. developed strongly on tea in Java in the honey-dew exuded by *Tachardia* sp. Leaf function was interfered with; and in some cases partial defoliation resulted. Brushing the branches is recommended.—*Carl Hartley*.

2027. HALL, C. J. J. VAN. Voorloopige mededeeling over de wortelschimmels van de thee. [Preliminary account of the root diseases of tea.] Dept. Landb. Nijv. en Handel [Nederland.-Indië] Proefsta. Thee Mededeel. 58. 26-27. 1918.—Seven kinds of root diseases are briefly considered and ascribed to the following fungi: *Rosellinia* (*bothrina*?), *R. (bunodes?)*, *R. sp.*, *Ustilina zonata*, *Poria hypolateritia*, *Hymenochaete noxia*, and *Armillaria*?.—*R. D. Rands*.

2028. HEMMI, TAKEWO. On the occurrence of *Mycosphaerella* wilt of muskmelons in Japan. Phytopathology 12: 394-397. 1922.—The occurrence in Japan of *Mycosphaerella citrullina* (Smith) Gross on muskmelon, cucumber, and on a kind of gourd (*Lagenaria vulgaris* var. *gourda* Ser.) is reported.—*B. B. Higgins*.

2029. HURSH, C. R. The relation of temperature and hydrogen-ion concentration to urediniospore germination of biologic forms of stem rust of wheat. Phytopathology 12: 353-361. Fig. 1-7. 1922.—Two biologic forms of *Puccinia graminis*, differing markedly in their ability to parasitize certain varieties of wheat, were selected for this study. The percentage germination of the urediniospores of the 2 forms was compared in solutions of various H-ion concentration and at temperatures of 10, 20, and 30°C. One form was decidedly more tolerant than the other to variations in temperature and H-ion concentration, showing that biologic forms may be demonstrated by specific physiological reactions. Tolerance to variations in temperature and in H-ion concentration was, in this instance, associated with a wider range of hosts.—*B. B. Higgins*.

2030. PELTIER, GEORGE L. A study of the environmental conditions influencing the development of stem rust in the absence of an alternate host. 1. The viability of the urediniospores of *Puccinia graminis* Triticum form III. Nebraska Agric. Exp. Sta. Res. Bull. 22. 15 p., 3 fig. 1922.—The author reports experiments on the viability of urediniospores of stem rust of wheat under controlled conditions. A series of temperatures were used ranging from 5 to 30°C., at 5° intervals. The spores were submitted at each temperature to relative humidities ranging from 0 to 100 per cent at approximately 10 per cent intervals. The viability of the spores was determined by germination tests in the laboratory and by infection tests in the greenhouse. The conclusions reached are: (1) The influence of relative humidity on the viability of the urediniospores of *Puccinia graminis* Triticum form III is very pronounced and closely associated with temperature; (2) at high relative humidities, depending somewhat on the temperature, the percentage of germination is low and the period over which the spores are viable is very short; (3) the same relation exists at the low relative humidities except that it is not so pronounced and is more variable; (4) the highest percentage of germination and

the longest viable period of the spores occur at the medium relative humidities. At the medium relative humidities high temperatures lower the percentage of germination and shorten the viable period while at low temperatures the opposite occurs.—*T. A. Kiesselbach.*

2031. SIGGERS, PAUL V. *Torula ligniperda* (Willk.) Sacc., a hyphomycete occurring in wood tissue. *Phytopathology* 12: 369-374. *Pl.* 25. 1922.—In testing the strength of blocks, using shipments of yellow poplar (*Liriodendron tulipifera* L.) and white ash (*Fraxinus americana* L.), the strength values varied considerably although the wood appeared sound. Microscopic examination showed that hyphae and spores of a fungus, later identified as *Torula ligniperda* (Willk.) Sacc., were present in the lumen of the cells. The fungus was isolated from the poplar wood, and its effect on sterile blocks of several species was studied.—*B. B. Higgins.*

2032. STONE, R. E. Leaf scorch or Mollisiose of the strawberry. *Phytopathology* 12: 375-380. *Fig.* 1-3. 1922.—The symptoms and etiology of the disease and the relative susceptibility of strawberry varieties are discussed. The disease appears in the early spring as small, irregular, purple blotches on the leaves and as purple streaks on the leaf petioles and flower peduncles. The blotches enlarge rapidly, and their centers die and turn gray. As the blotches enlarge they coalesce until by mid-summer the entire leaf is frequently involved and killed. On the dead spots the acervuli of a fungus identified as *Marsonia Potentillae* (Desm.) Fischer were found. The following spring ascocarps of *Mollisia earliana* (E. & E.) Sacc. were found on the dead leaves. Cultures obtained from single ascospores of this fungus produced conidia of the *Marsonia* type. Strawberry plants inoculated with conidia from these cultures developed typical leaf scorch symptoms, indicating the genetic connection of the 2 spore forms.—*B. B. Higgins.*

2033. STOUTAMIRE, RALPH. What makes the orange mushy? *Florida Grower* 28¹³: 4-5. 1922.—This is a popular description of the softening influence of stem-end rot (*Phomopsis Citri*) upon orange fruit.—*J. C. Th. Uphof.*

2034. WILTSHIRE, S. P. A disease of Michaelmas daisies. *Univ. Bristol Ann. Rept. Agric. and Hort. Res. Sta.* 1920: 84-85. 1920.—A disease which the author thinks is caused by a fungus of the *Fusarium* type causes a yellowing of the bottom leaves, checking of growth, sometimes premature flowering, and earlier dying of individual shoots. "A fungus has been isolated from the diseased tissues, and preliminary inoculation experiments indicate that it is the cause of the disease." The fungus grows in the conductive tissue and thus stops the water supply. No control method is recommended except marking diseased plants in order to avoid propagating from them, and burning of infected material.—*W. H. Chandler.*

2035. WILTSHIRE, S. P. The bark canker disease of apples. *Univ. Bristol Ann. Rept. Agric. and Hort. Res. Sta.* 1920: 81. 1920.—Cankers on the main branches of apple trees caused by *Myxosporium corticolum* Edgerton were found in the orchards at Long Ashton. The injury seemed to be slightly worse than that reported in the U. S. A.—*W. H. Chandler.*

2036. WILTSHIRE, S. P., and G. T. SPINKS. Apple tree canker. *Univ. Bristol Ann. Rept. Agric. and Hort. Res. Sta.* 1920: 82-83. 1920.—This is a discussion of the infection of young apple buds by *Nectria ditissima*. Cracks in the leaf-scar tissue seem to be a means of entrance for the fungus. As long as the leaves remained on the tree no autumn infection occurred. Spraying seemed to reduce the number of cankers formed. A more complete report is promised.—*W. H. Chandler.*

DISEASES CAUSED BY BACTERIA

2037. GOSSARD, H. A., and R. C. WALTON. Dissemination of fire blight. *Ohio Agric. Exp. Sta. Bull.* 357. 81-126, *fig.* 1-13 + 3 *fig.* unnumbered. 1922.—This bulletin comprises a report of a series of studies on fire blight dissemination conducted by the junior author in

cooperation with the department of entomology. It was found that *Bacillus amylovorus* may live in honey for 72 hours or more. Infections were obtained by the use of honey taken from 3 hives, by the use of apple pollen removed from the baskets of bees caught as they were entering the hive, and by inserting the mouth parts of bees into incisions made in tender twigs. The fire blight organism was found to be alive in aphid honey-dew after 7 full days, and to survive in peach, plum, and cherry nectar for 5 days. Rain was proved to be the most important factor in the dissemination of infection over a tree after centers are established, and especially if the latter are near the top. It was estimated that 50-90 per cent of blossom infection was accomplished by infected rain water. Seventy-two hours after pollination, blossoms are only slightly susceptible to infection, and after 144 hours they are practically immune. Several sucking and boring insects were observed to be carriers of fire blight. All experiments with ants were negative. The authors suggest that there is ample ground for crediting blossom fire blight with traveling northward with the zone of inflorescence to a greater extent than is now accepted. The fire blight organism was not found to be sensitive to the electric violet ray.—R. C. Thomas.

2038. GROENEWEGE, J. Landbouwkundige onderzoekingen over de slijmziekte. [Agricultural investigations of slime disease.] Dept. Landb. Nijv. en Handel [Nederland.-Indië] Alg. Proefsta. Landb. Mededeel. 12. 79 p., 16 pl. 1922.—The peanut (*Arachis hypogaea*), even with wounded roots, may remain healthy in soil or water cultures containing the causal organism (*Bacterium Solanacearum*) of this disease. This bacterium is believed to be a normal constituent of the soil flora, and the incidence of the disease which it causes is dependant on environmental conditions favoring the susceptibility of the host. Susceptibility of peanut and tobacco is due to lack of soil oxygen. When diseased plants are found in soils in good general tilth the roots are seen to be decayed at and below points where they pass through clods. These clods exhibit an internal blue color due to imperfectly oxidized iron compounds. Death of the root at such a point is directly due to oxygen hunger; the bacteria subsequently use the lesion as an infection port. In pot experiments, 61 per cent of the plants growing in paraffined pots wilted, while in ordinary unglazed pots only 18 per cent showed disease symptoms. The rapid loss of virulence of *B. Solanacearum* in artificial cultures reported by other investigators was not observed. Honing's failure to secure infection with strains long in cultivation was due to the use as inoculum of subcultures which were 1-2 weeks old and therefore dead. The peanut is easily grown in a solution containing 0.1 per cent KNO_3 and 0.05 per cent each of CaSO_4 , MgSO_4 , and $\text{Ca}_3(\text{PO}_4)_2$ with a trace of Fe. In water cultures very young plants infected to the point of wilting, and with bacteria already in the petioles, in some cases recovered. The plants most diseased in water cultures were obtained under the driest atmospheric conditions. In both peanut and tobacco unquestionably infected plants developed new roots which appeared free from bacteria. It is concluded that the bacteria can spread only in the direction of the transpiration stream. The penetration of aerated water into the soil following the root downward is indicated by the finding of orange (therefore ferric) particles in otherwise blue soils. The presence of fresh organic matter in the soil is thought to increase the amount of disease by exhausting the oxygen supply. Adding sugar to pot cultures at the rate of approximately $\frac{1}{4}$ and $\frac{1}{2}$ per cent by weight, resulted in decreased disease. This is explained in connection with the effect of the sugar on the water-holding capacity of the soil. The fact that the disease in tobacco is more serious in north Sumatra than in Mid-Java is attributed to the poorer soil cultivation in the former locality.—Carl Hartley.

2039. JARVIS, E. Bureau of sugar experiment stations. Combating sugar cane pests. Cane pests on the Herbert River. Australian Sugar Jour. 14: 413-416. 1922.—The gumming disease (*Bacillus vascularum*) is prevalent throughout the Herbert River district, occurring mostly in Clarke's Seedling (H. Q. 426). The cane variety Badila is already infected and it is feared may become more so. The variety H. Q. 409, although practically immune to the gumming disease, is unpopular here because of its slow growth and tendency to arrow freely and very early. Selection of clean cane, planting of immune varieties, good drainage and cultivation of land, and the use of green manures are advised.—A brief discussion is also given to

the pest-destruction fund, to damage by rats and by white ants, and to a tachinid fly parasite of the cane borer.—*C. Rumbold*.

2040. MARTIN, J. P. Variation in color of pear blight exudate. *Phytopathology* 12: 399-400. 1922.—A dark green color was noted in the first exudate from a single loquat (*Eriobotrya japonica* Lindl.) twig inoculated with *Bacillus amylovorus* (Bur.) De T., while from other twigs inoculated at the same time the exudate had the normal color.—*B. B. Higgins*.

2041. THOMAS, ROY C. A bacterial rosette disease of lettuce. *Ohio Agric. Exp. Sta. Bull.* 359. 197-214, 8 fig. 1922.—A bacterial rosette disease of lettuce found chiefly in greenhouses in Ohio is reported. The disease closely resembles, and is thought to have been previously confused with, the older recognized form of rosette due to *Rhizoctonia*. Inoculation experiments have demonstrated the pathogenicity of the bacterium associated with the disease, and it is thought that the organism can survive indefinitely in the soil. Control experiments have shown that the formaldehyde-drench plan is an effective method of eradication. Steam sterilization is also suggested. Cultural studies of the pathogen have revealed points of similarity and of difference between it and another one causing a similar disease previously reported from South Carolina. The name *Aplanobacter Rhizoctonia* n. sp. is suggested for the Ohio organism.—*R. C. Thomas*.

2042. WILTSHIRE, S. P. A bacterial infection of plum trees. *Univ. Bristol Ann. Rept. Agric. and Hort. Res. Sta.* 1920: 78-80. 1920.—Trunks of large plum trees were found to have been killed, the part first killed being about 3½ feet above ground. Bacterial masses were constantly present in the diseased cortex of the many specimens examined, together with fungus hyphae and in many cases *Cytospora* fructifications. “. . . the association of the bacteria with the disease in such a number of cases is extremely suggestive and appears to be more than an accidental occurrence. The relationship between the bacterial organism and the fungus *Cytospora* is only a matter of conjecture. . . .”—*W. H. Chandler*.

DISEASES CAUSED BY ANIMAL PARASITES (INSECTS, NEMAS, PROTOZOANS, ETC.)

2043. INSTITUT INTERNATIONAL D'AGRICULTURE. Enquête sur la lutte contre la mouche des olives (*Dacus oleae*) dans les divers pays. [Investigations on the control of the olive fly.] vi + 89 p. Imprimerie de la Chambre des Députés: Rome, 1922.—This report is an assemblage of various papers from different countries, relating to olive-fly control. Several bibliographies list the principal publications dealing with this insect, and its control and relation to disease transmission.—*Frederick V. Rand*.

2044. SCHLUPP, W. F. The principal orchard pests and how to control them. 29 p., 5 fig. Johannesburg, [192-?].—This is a brief, popular handbook dealing with the insects of the orchard and their control. Following a general introduction, the codling moth, and various fruit flies, aphids, and scale insects are in turn briefly discussed.—*Frederick V. Rand*.

2045. WAHL, BRUNO. Auftreten des Kolorado-Kartoffelkäfers in Südfrankreich. [Appearance of Colorado potato beetle in southern France.] *Oesterr. Zeitschr. Kartoffelbau* 2: 24. 1 fig. 1922.—The area infested is already 250 square km. and constitutes the largest area in Europe into which this potato pest has yet escaped. The warm climate of France is thought likely to be conducive to its further spread.—*F. Weiss*.

INFECTIOUS CHLOROSES (MOSAIC AND PEACH YELLOWS GROUPS, ETC.)

2046. BRUNER, STEPHEN C. Bibliographia. La enfermedad de las “rayas amarillas” en la caña. [Bibliography. The yellow stripe disease of sugar cane.] *Rev. Agric. Com. y Trab. Cuba* 5: 32-33. 1922.—This is a critical review of MOISES SIMONETTO's *La Enfermedad de las Rayas Amarillas en la Caña* (Su Importación y Extensión—Año y Medio de Observaciones en Cuba) [see *Bot. Absts.* 11, Entry 1776].—*G. R. Hoerner*.

2047. GARDNER, MAX W., and JAMES B. KENDRICK. Overwintering of tomato mosaic. Bot. Gaz. 73: 469-485. Pl. 17. 1922.—The authors find no evidence for the transmission of mosaic by way of the seed. They were successful in proving that the inoculum may overwinter in perennial herbs. Various species of the genus *Physalis* are important in this respect. Mosaic was found affecting *Physalis subglabrata*, *P. virginiana*, *P. heterophylla*, and *Solanum carolinense*. Evidence was obtained that the disease had spread to *Physalis* plants 200-400 feet away from infected tomato fields. Aphids and flea beetles are believed to play a part in the transmission to *Physalis* plants. The eradication of solanaceous perennial herbs in and near tomato fields is recommended as a control measure.—B. W. Wells.

PARASITIC PHANEROGAMS

2048. HERBERT, D. A. The parasitism of *Olax imbricata*. Philippine Agric. 11: 17-18. 1 fig. 1922.—*Olax imbricata* Blume (Malabaguio), a large woody vine with well developed leaves and a shallow and wide root system, occurs sparingly in Mount Makiling. Its large, rather soft roots branch and ultimately give rise to fragile white rootlets, which in contact with other roots produce a lateral haustorium of the same type as that found in the Santalaceae. Haustoria attached to a host root derive salts and water, as well as organic matter, from the host plant. Two of the 3 host plants observed were legumes. Self parasitism is common, and the best development of haustoria was found on roots of *Olax* itself.—Sam F. Trelease.

NON-PARASITIC DISEASES

2049. DEUSS, J. J. B. Kloetasch in theetuinien. [Ash from the Kloet in tea gardens.] De Thee 1: 67-68. 1920.—The eruption of the Kloet in East Java resulted in the deposition of an ash layer 5-20 cm. thick in a tea plantation. Defoliation and death of young plants followed. As a result of previous experience in this locality the ashes were worked into the upper soil as thoroughly as possible in order to prevent cementing into an impervious layer. The working in of as much organic matter as possible was also advised. On other plantations where the layer was only 1-1½ cm. deep it was turned under without injury to the plants.—Carl Hartley.

2050. FABRICIUS. [Rev. of: GRAEBNER, PAUL. Handbuch der Pflanzenkrankheiten begründet von Paul Sorauer. Vol. I. Die nichtparasitären Krankheiten. (Non-parasitic plant diseases.) 4th ed., 959 p., 264 fig. Paul Parey: Berlin, 1921 (see following entry).] Forstwiss. Centralbl. 44: 34-37. 1922.—This work is based on the theory that the chief causes of disease or weakness in plants, including susceptibility to parasitic diseases, are to be found in climatic, soil, or cultural conditions, and that the most effective means of combating the diseases are development of resistant forms and proper plant sanitation. The book does not overlook forestry and tree diseases, as so many books on plants do, but contains much of direct interest to foresters. It does omit some tree ailments, such as sun-scald.—W. N. Sparhawk.

2051. GRAEBNER, PAUL. Handbuch der Pflanzenkrankheiten begründet von Paul Sorauer. Vol. I. Die nichtparasitären Krankheiten. [Handbook of plant diseases founded by Paul Sorauer. 1. The non-parasitic diseases.] 4th ed., xv + 959 p., 264 fig. Paul Parey: Berlin, 1921.—This work constitutes a completely rewritten edition of volume 1 of SORAUER's Handbuch. In the words of Graebner, "The literature of this previously neglected and at the same time economically important subject had become so enormously increased that it was necessary to introduce extensive supplementary studies in spite of the fact that I had presented the non-parasitic diseases as a teacher for almost a quarter of a century. All using the third edition will recall how exceedingly difficult it is to find one's way through the complex subject matter. Therefore, so far as possible in adapting the present edition to the classification of Sorauer, I have undertaken a sharp delimitation of the sections and chapters in order to facilitate an understanding of the subject by the student and a rapid orientation by the specialist. As far as possible numerous references have been added as footnotes.—A number of new figures, especially photographic reproductions, have been included. To my

regret I have not succeeded in complying with the wish of the publisher to reduce the size of the work. On the contrary, through numerous supplementary additions, appearing especially in the corrections, it is even enlarged."—Under the general part of the work 3 sections deal respectively with historical phases of the subject, the nature of disease, and growth changes due to different geographical situation. In the 2nd part the special phases of the subject are exhaustively discussed under the following sections: (1) diseases caused by unfavorable soil conditions; (2) the influence of humidity, dryness, and movements of the air; (3) effects of heat and light; (4) wounds; (5) diseases caused by injurious gases and liquids; (6) the diseases exhibiting abnormal enzymatic functions under which are included the mosaic, sereh, and yellows groups, and several gummoses and resinoses.—This work is not to be confused with the *Lehrbuch der Nichtparasitären Pflanzen Krankheiten* [see Bot. Absts. 9, Entry 418], which is a concise textbook intended especially for students. [See also preceding entry.]—*Frederick V. Rand.*

2052. LA RUE, CARL D. **Lightning injury to *Hevea brasiliensis*.** *Phytopathology* 12: 386-389. 1922.—In the type of injury here discussed the current of electricity seems to pass principally through the cambium and young sap wood without external injury, such as tearing of the bark or branches. Usually one or more trees are killed and the surrounding trees more or less severely injured. The injury is most severe just back of the tip of a branch. When the injury is slight only the tips of the branches die. Death of the tissue is followed almost immediately with infection by *Diplodia*. Lightning injury to *Hevea* is, therefore, frequently diagnosed as "die back."—*B. B. Higgins.*

2053. SNELL, WALTER H., and NATHANIEL O. HOWARD. **Notes on chemical injuries to the eastern white pine (*Pinus Strobus* L.).** *Phytopathology* 12: 362-368. *Pl. 24, fig 1-2.* 1922.—Two instances of chemical injury to white pine trees are recorded. In one case the trees in an area approximately $\frac{1}{2} \times \frac{1}{4}$ mile in extent, adjacent to a brick kiln, were seriously injured, apparently by fumes from soft coal burned in the kiln. The leaves were reddish brown and from a distance appeared to be entirely dead; but close examination showed that the bases of many leaves were still green. Leaves of several broad-leaved species also showed injury. In the other case white pine trees were killed or severely injured by calcium chloride dissolved from metal containers which stood under the trees about a month.—*B. B. Higgins.*

DISEASES OF UNKNOWN CAUSE

2054. LEES, A. H. **A method of identifying reversion of black currants.** *Univ. Bristol Ann. Rept. Agric. and Hort. Res. Sta.* 1920: 66-70. *Pl. 4.* 1920.—Suggestions are given as to methods of identification and control of this disease. [See also Bot. Absts. 9, Entry 403; 11, Entry 4475].—*W. H. Chandler.*

2055. PALMER, W. B. **Pecan rosette.** *Proc. Ann. Convention Nation. Nut Growers' Assoc.* 20: 72-78. 1921.—This is a popular lecture. In the author's opinion water cannot be the main cause of rosette since the disease occurs under such widely varying water relations. After briefly reviewing the parts played by the various elements of plant nutrition and the results of experience in his own orchard, the author states that "Rosette can then be defined as that condition of a tree caused primarily by the lack of available nitrogen in the soil in which the tree grows or the inability of the tree to appropriate the nitrogen."—It is the rich nitrogen supply in the alluvial bottom lands, he says, that prevents rosette on such soils, and this is the deficient element in most soils. Rosette was relieved in his own orchard by heroic applications of nitrogen, but he does not think that the same result would necessarily follow in all orchards.—*Frederick V. Rand.*

2056. RAND, FREDERICK V. **Pecan rosette: its histology, cytology, and relation to other chlorotic diseases.** *U. S. Dept. Agric. Bull.* 1038. 42 p., 12 pl., (1 colored). 1922.—After a brief discussion of different types of plant chloroses a review is given of previously published histological and cytological studies relative to infectious chloroses and to chloroses caused

directly by soil or atmospheric conditions.—The 2nd part of the paper reviews the previous work on pecan rosette and then details the present histological and cytological investigation.—“As a class, the chloroses due to soil or atmospheric conditions are rather general effects which are more or less comparable to starvation, overfeeding, or direct poisoning. . . . In the specific chlorotic diseases of an infectious nature fundamental derangements in both physiological and structural development are simultaneously brought about. . . . The histological and cytological evidence suggests that pecan rosette in its specific sequence of signs and in the complexity of the structural and physiological derangements bears far more similarity to the known infectious chloroses than to those caused by soil or climatic conditions. Whether in this particular disease the factors responsible for alterations in the normal structure and metabolism must be introduced into the plant from without, or whether they originate within the plant itself, is a question yet to be answered; but whatever the ultimate solution of the problem the cause will undoubtedly not be found in any simple soil or water relation.”—A bibliography of 85 titles is appended.—*Frederick V. Rand.*

2057. WEAVER, WALTER. Pecan rosette. Proc. Ann. Convention Nation. Nut Growers' Assoc. 20: 67-72. 1921.—This is a popular lecture in which the author expresses the opinion that pecan rosette is strictly a moisture problem and due to excess of transpiration over intake. In support of this theory he draws the following from his own experience: No improvement after liberal feeding; quick results from manure mulch without appreciable rainfall; improvement under mulch with but little new growth; aggravation of rosette near barnyards with abundant food supply; marked aggravation following drought; appearance of rosette in late summer when the soil water supply is at a minimum and when high temperatures cause the greatest transpiration; and the usual absence of rosette in neglected orchards and near buildings where food is scanty and soil water is more abundant on account of shading, and where the roots are not disturbed or exposed to high temperatures. The rosette formation, indicating an adaptation to reduce transpiration, and the high percentage of pure water present in plants lend further support, he says, to this theory. The main suggestions for control include applications of potash and the use of cover crops.—*Frederick V. Rand.*

GENERAL AND MISCELLANEOUS PATHOLOGICAL LITERATURE

2058. ANONYMOUS. Control of insect pests and diseases of vegetable crops. Ohio Agric. Exp. Sta. Monthly Bull. 7: 89-97. 1922.—Methods which have proved efficient for the control of the most serious vegetable diseases found in Ohio are tabulated. A brief discussion is given of general cultural practices emphasizing sanitation, and brief directions are included for the preparation and use of current fungicides and methods of sterilization.—*R. C. Thomas.*

2059. B[ERNARD, CH.] Wortelziekten en boomstronken. [Root diseases and tree stumps.] De Thee 1: 25-26. 1920.—A planter reports much root disease in tea in the immediate vicinity of stumps of *Celtis cinnamomea*.—*Carl Hartley.*

2060. CHASE, W. W. The principal parasites of the peach. Georgia State Bd. Entomol. Bull. 61. 43 p., 19 fig. 1922.—This revision of bulletins 43 and 57 gives a spray schedule for peaches and discusses various fungus and insect parasites. Special attention is given to the relation of brown rot (*Sclerotinia fructigena* Schröt.) to the curculio. It is shown that a severe infestation of this insect increases the disease, and that there is also a relation between brown rot and excessive growth and moisture. Other parasites discussed are peach scab (*Cladosporium carpophyllum* Thum.), leaf curl (*Exoascus deformans* (B.) Fuckel.), peach tree borer (*Sanninoidea exitiosa* Say), plum curculio (*Conotrachelus nenuphar* Herbst.), San Jose scale (*Aspidiotus perniciosus* Comstock), shot-hole borer (*Scolytus rugulosus* Ratz), and nematode (*Heterodera radicola* (Greff.) Mul.).—*T. H. McHatton.*

2061. DEMAREE, J. B. Pecan disease investigations during 1921. Proc. Ann. Convention Nation. Nut Growers' Assoc. 20: 37-39. 1921.—This lantern slide lecture was given to ac-

quaint the growers with the lines of work being done rather than to show the results obtained. Experiments on rosette, scab, and kernel spot are briefly described and the locations given.—*Frederick V. Rand.*

2062. DOIDGE, ETHEL M. *Diseases of the apple, pear and quince.* 50 p., 17 fig. Johannesburg, [1917 ?].—This is a popular handbook briefly discussing the following diseases and their control: bitter rot (*Glomerella cingulata* (Stonem.) S. & S.), black rot (*Sphaeropsis Malorum* Peck), leaf blight (*Fabraea maculata* Atk.), scab (*Venturia inaequalis* Cke., and *V. pirina* Aderh.), powdery mildew (*Podosphaera leucotricha* (E. & E.) Salm.), bitter pit, die-back (*Valsa leucostoma* (Pers.) Fr.), apple cracking disease (*Coniothecium chomatosporium* Corda), crown gall (*Bacterium tumefaciens* Erw. Sm.), cankers (*Glomerella cingulata*, *Phylospora Cydoniae*, *Valsa leucostoma*, *Nectria ditissima* and sun scald). A general section on the prevention of diseases follows.—*Frederick V. Rand.*

2063. DOIDGE, ETHEL M. *Potato disease.* 49 p., 26 fig. Johannesburg, [1920].—This is a popular handbook briefly discussing the following diseases and their control: early blight or leaf curl (*Macrosporium Solani* E. & E.), scab (*Actinomyces chromogenus* Gasp.), corky or powdery scab (*Spongospora subterranea* (Wallr.) Johns.), black scab canker or wart (*Synchytrium endobioticum* Pers.), bacterial wilt (*Bacterium Solanacearum* Erw. Sm.), Rhizoctonia disease (*Corticium vagum* var. *Solani* Burt.), late blight (*Phytophthora infestans* de By.), and internal brown fleck.—*Frederick V. Rand.*

2064. EZEKIEL, WALTER N. *Photographing tube cultures.* *Phytopathology* 12: 399. 1922.

2065. MANUEL, H. L. *Faulty lime in Bordeaux mixture.* *Agric. Gaz. New South Wales* 33: 759. 1922.—Emphasis is placed on the fact that lime intended for Bordeaux mixtures should not be allowed to become carbonated.—*L. R. Waldron.*

2066. PENZIG, O. *Pflanzen-Teratologie systematisch geordnet.* [Plant teratology.] 2nd ed., much enlarged, Vol. I. xviii + xi + 283 p. 1921; Vol. II. 548 p. 1921; Vol. III. 624 p. Gebrüder Borntraeger: Berlin, 1922.—“Since the appearance more than twenty-five years ago of the first edition of this work, the observational material concerning plant anomalies and monstrosities has increased enormously and is to be found in many hundreds of papers and larger works distributed through the botanical literature of all lands. The time is, therefore, ripe for an exhaustive review of the observed facts gathered by various authors, and of their significance in the morphology and taxonomy of the individual groups discussed.”—Following the prefaces, introduction, and glossary the main part of volume 1 is given up to an alphabetically arranged bibliography. The remainder of the work gives bibliographical references and abstracts of published teratological data arranged according to the taxonomic position of the plants discussed. Volume 2 deals entirely with the dicotyledonous group Polypetalae, while volume 3 takes up the dicotyledonous Gamopetalae, and the monocotyledons, pteridophytes, bryophytes, fungi, lichens, and algae.—*Frederick V. Rand.*

2067. RAMSAY, A. A. *Storage experiments with lime intended for sprays.* *Agric. Gaz. New South Wales* 33: 747-749. 1922.—Fresh lime was slaked and kept under water for 172 days. A series of analyses during this period showed no appreciable diminution of the efficacy of the product.—*L. R. Waldron.*

2068. WRIGHT, HORACE J. *Plant pests and parasites. Preventives and remedies.* 32 p., 1 fig (on cover). “County Life.” London, 1922.—This brief, popular handbook takes up the pests and parasites (and their control) among (1) flowers, (2) fruits, and (3) vegetables. Sections on general enemies, and on useful washes and dressings are appended.—*Frederick V. Rand.*

PHARMACOGNOSY AND PHARMACEUTICAL BOTANY

HEBER W. YOUNGKEN, *Editor*E. N. GATHERCOAL, *Assistant Editor*

(See also in this issue Entries 1631, 1644, 1708, 1822, 1865, 1867, 1887)

2069. ANONYMOUS. Potash from kelp in Australia. Jour. Dept. Agric. Victoria 18: 498. 1920.—The average potash contents of the ash is about 14 per cent. Individual samples have yielded 30 per cent.—*Wm. E. Lawrence.*

2070. CHEEL, EDWIN. Notes on the "scarlet" and "blue" pimpernel. Australian Nat. 5: 18-19. 1922.—*Anagallis arvensis* is poisonous to birds. Some reasons are given for considering *A. arvensis* and *A. coerulea* as distinct species.—*T. C. Frye.*

2071. HASKIN, LESLIE L. The death Camas. Amer. Bot. 28: 141-143. 1922.

2072. HERBERT, D. A. Cyanophoric plants of the Makiling region. Philippine Agric. 11: 11-16. 1922.—By modifications of Guignard's sodium picrate test, 110 species, belonging to 41 families,—including native Philippine species, introduced fodder and food plants, ornamental plants, and weeds,—were tested for the presence of hydrocyanic acid, with the result that 86 species were characterized by its presence. The distribution of hydrocyanic acid in the plant was not uniform, even in species belonging to the same genus; in the majority of cases the greatest amount was in the bark. Nor was the acid always present in a given species.—*Sam F. Trelease.*

2073. KING, HAROLD. The isolation of muscarine, the potent principle of *Amanita muscaria*. Jour. Chem. Soc. [London] 121: 1743-1753. 1922.—Details are given of a method of isolating pure muscarine from fresh *A. muscaria* tissue. The distribution of muscarine in the various fractions obtained was determined by 2 methods of physiological assay: one consisted in observing the action of muscarine chloride on a loop of rabbit intestine, a dilution of 1 part in 600 millions giving an appreciable effect; the other in the effect on toad's heart, a distinct inhibition resulting at a dilution of 1 part in 75 millions. Attention is called to the difficulty of separating choline and muscarine. Other substances obtained from tissue of *A. muscaria* were ergosterol, 1-leucine, mannitol, and fumaric acid.—*F. E. Denny.*

2074. MELL, C. D. The early uses of the yaupon. Amer. Forestry 28: 531. 1922.—The author briefly discusses *Ilex vomitoria* and its uses in the preparation of a tea and as a diuretic.—*Chas. H. Otis.*

2075. SAYRE, L. E. Standards of purity for medicinal agents. Trans. Kansas. Acad. Sci. 30: 232-233. 1919/21 [1922].—"This paper is contributed largely to give information as to what is now in evidence so far as medicinal standards are concerned and what the new revision committee of the U. S. Pharmacopoeia (10th) will be obliged to face."—*F. C. Gates.*

DIFFUSION, PERMEABILITY

2079. BROWN, WILLIAM. On the preparation and use of collodion osmometers. *Ann. Botany* 36: 433-439. 1922.—A method is described of preparing thimble-shaped membranes of collodion for use as osmometers. They are accurate, easy to make and manipulate, and by treatment with alcohol of different strengths can be brought to any desired degree of permeability. The method of using them is also described and the results of experiments performed with them are given.—*W. P. Thompson*.

2080. TRÖNDLE, A. *Neue Untersuchungen über die Aufnahme von Stoffen in die Zelle*. [Cell absorption.] *Biochem. Zeitschr.* 112: 259-285. 1920.—Palisade cells of *Buxus sempervirens* and *Acer platanoides* absorbed no KCl or NaCl when narcotized by ether or chloral hydrate. At lower concentrations of the narcotics, slow absorption, as determined by plasmolysis, occurred. After treatment with dilute oxalic or hydrochloric acid, the palisade cells of *Buxus sempervirens* absorbed NaCl in proportion to the outer concentration instead of at a constant rate, as in the checks. *Spirogyra* (*S. majuscula* and *S. sp.*) cells absorbed quinine, caffeine, or piperidine, the product of outer concentration and the time required to precipitate the tannin present in the vacuole being a constant. In the presence of traces of acid no absorption occurred. Alkaloid bases, salts, and salts in the presence of dilute acid penetrated the cells in the same time when killed by chloroform.—*H. D. Hooker, Jr.*

WATER RELATIONS

2081. COUPIN, HENRI. *Détermination de l'optimum d'humidité du milieu extérieur chez les Oscillaires*. [The determination of the optimum humidity for the external medium of *Oscillarias*.] *Compt. Rend. Acad. Sci. Paris* 174: 822-824. 1922.—The author finds that the optimum humidity for the growth of this blue-green alga is that provided by a 1 per cent solution of gelatin.—*C. H. Farr*.

2082. SINGH, KHARAK. Development of root system of wheat in different kinds of soils and with different methods of watering. *Ann. Botany* 36: 353-361. 3 fig. 1922.—Specially planned experiments showed that wheat plants in pots grow better when watered from below than when watered from above. With light soil the difference is most marked in young plants; with heavy soils it becomes most conspicuous at later stages. Growth is best in pure sand over a layer of farm-yard manure. It is better in a mixture of 25 per cent sand and 75 per cent Rothamsted soil than in either a mixture of 50 per cent of each or pure Rothamsted soil.—*W. P. Thompson*.

MINERAL NUTRIENTS AND SALT RELATIONS

2083. GUILLEMIN, MADELEINE, and W. P. LARSON. The relation between the fixed and free salts of bacteria. *Jour. Infect. Diseases* 31: 344-355. 1922.—The diffusion of salts out of the dead cells of *B. coli* is demonstrated. The free salts are found to predominate over the fixed in the bacterial cells.—*R. V. Allison*.

2084. JONES, LINUS H., and JOHN W. SHIVE. Influence of wheat seedlings upon the hydrogen ion concentration of nutrient solutions. Bot. Gaz. 73: 391-400. 1922.—Solutions of Tottingham's series were used. Marked differences were found in the rates of reaction change. Those solutions resistant to change, indicating buffer action, were those with the highest volume-molecular proportions of soluble phosphate salts, though 1 exception to this was found. A tendency for the solutions to approach a common pH value (always through increase of the H-ion content) was observed. A solution modified by substituting $(\text{NH}_4)_2\text{SO}_4$ for KNO_3 in equivalent osmotic concentrations "has shown that the pH values of these solutions are not greatly altered by contact with the roots of young wheat plants between the ages of 4 and 5 weeks, the tendency always being toward a slight increase in the H-ion concentration of the solution during growth intervals of 3 or 4 days without renewal of the solutions. It is thus easily seen that for certain types of culture studies in which it is desirable to maintain the H-ion concentrations of the nutrient media within comparatively narrow variation limits, solutions of this kind possess marked advantages over those in which the H-ion concentrations are rapidly decreased by the action of the plants."—B. W. Wells.

2085. LESAGE, PIERRE. Étude des plantes salées, pendant la période où se produisent des anomalies. [Plants in hypertonic salt solutions, during the period of abnormal development.] Compt. Rend. Acad. Sci. Paris 174: 56-58. 1922.—In these further studies on the effect of different concentrations of sodium chlorid on the fruiting of *Lepidium sativum*, the author was able to grow plants to maturity in concentrations as high as 14 per cent; but the germination of the seed produced was very poor. The salt solution affects the absorption of water and ions, such as potassium. The seed of plants grown in cultures with high salt content are shorter and thicker than the controls. Sixty-five of 265 fruits of plants grown in high salt concentration showed 3-4 locules; only 1 out of 90 control plants had this abnormality. Little evidence is presented that this abnormality is inheritable. [See also Bot. Absts. 9, Entry 482.]—C. H. Farr.

2086. MASCHHAUPT, J. G. De samenstelling onzer cultuurgewassen in opeenvolgende groeiperioden. [The composition of crops in successive periods of growth.] Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefsta. 25: 131-139. 1921.—This paper includes results of investigations made to determine: (1) during what part of the growing period the plant obtains mainly nitrogen or phosphorus; (2) whether the amount of nitrogen and ash constituents in the harvested crops is the maximum present at any period during growth; and (3) whether at the end of vegetative growth these substances are returned to the soil.—The soil used was a poor sand, the plot was fertilized with 80 kgm. nitrogen as $(\text{NH}_4)_2\text{SO}_4$, 96 kgm. P_2O_5 as Thomas slag, and 210 kgm. K_2O in the form of "patent kali."—Potatoes were planted April 26, 1919, and harvests and analyses made on June 4 and 20, July 4 and 26, August 11 and 29. Leaves and tubers but no roots were analyzed.—The weight (dry) of the leaves rises until the end of July, then decreases in early August. A marked decrease in the second half of August was due to dying of foliage. Nitrogen in the leaves is very high in the beginning, and then decreases slowly; in the tubers the nitrogen content decreases between July 4 and 26, but no more after that. It increases in the leaves to the beginning of July and is then seemingly transferred to the tubers, as the total nitrogen (leaves and tubers) seems to be constant. P_2O_5 decreases very much in the leaves, while in the tubers it seems to remain constant after an initial decrease. The total amount increases at the end of the growing period. Potassium increases in the leaves to early July, afterwards decreasing; in tubers it decreases very much during July, but increases later. SO_3 increases in leaves to July 26 and decreases after August 11, the total SO_3 increasing to the end. The Cl data are similar to those on SO_3 . CaO in leaves decreases to July 4 or July 26, the total amount increasing between July 4 and July 26 and then remaining constant. The MgO content is changeable in the leaves and constant in the tubers, the total increasing somewhat.—It was found that at the end of the growing period there is in potatoes no loss in nitrogen and ash constituents. What is lost in the leaves is deposited in the tubers. The slight decrease in Na_2O and CaO is possibly due to loss of foliage near the end of August.—A German résumé concludes the paper.—Peter J. Klaphaak.

2087. SAUVAGEAU, C., et G. DENIGES. A propos des efflorescences du *Rhodomenia palmata*; présence d'un xylane chez les algues floridées. [The efflorescence of *Rhodomenia palmata*; the presence of xylane in the red algae.] Compt. Rend. Acad. Sci. Paris 174: 791-794. 1922.—The efflorescence of this alga is found to be due to KCl, but not to mannite or trehalose. [See also Bot. Absts 11, Entry 3020.]—C. H. Farr.

PHOTOSYNTHESIS

2088. STOKLASA, J. Die Bedeutung der Radioaktivität des Kaliums bei der Photosynthese. III. [The significance of the radioactivity of potassium in photosynthesis.] Biochem. Zeitschr. 108: 173-184. 1920.—Reasons are given for considering that magnesium has no relation to photosynthesis. Carbon assimilation is considered a decomposition of potassium bicarbonate under the influence of light to formic acid, oxygen, and potassium carbonate, and the further decomposition of formic acid to formaldehyde and oxygen. The β - and γ -rays of potassium are thought to be important in photosynthesis.—H. D. Hooker, Jr.

METABOLISM (GENERAL)

2089. BRIDEL, MARC. Sur la présence d'un glucoside à essence dans les tiges foliées et les racines du *Sedum Telephium* L. [On the presence of a glucoside in the leafy shoots and roots of *Sedum Telephium*.] Compt. Rend. Acad. Sci. Paris 174: 186-188. 1922.—The amount of reducing sugar in the extract is increased after treating with invertin, and still more if treated with emulsin. This is taken as evidence of the presence of a glucoside upon which these enzymes act. The physical and chemical properties of the glucoside are described.—C. H. Farr.

2090. CLARK, E. P. The structure of fucose. Jour. Biol. Chem. 54: 65-73. 1922.—Fucose was prepared from *Ascophyllum nodosum* by an improved method. Fucose ($C_6H_{12}O_6$) may be considered as a methyl pentose. The positions of the hydroxyl groups on carbon atoms 2, 3, and 4, heretofore determined by purely chemical means, have been verified by a study of the optical properties of preparations from fucose.—G. B. Rigg.

2091. COHEN, CLARA. Über die Bildung von Acetaldehyd bei den Umsetzungen von Zucker durch Pilze. [Acetaldehyde formation in sugar decomposition by fungi.] Biochem. Zeitschr. 112: 139-143. 1920.—The formation of acetaldehyde from glucose by *Aspergillus cellulosa*, *Monilia candida*, *Mucor racemosus*, *M. Rouxii*, and *Oidium lactis* was demonstrated by using disodium sulphite or calcium sulphite.—H. D. Hooker, Jr.

2092. COMBES, RAOUL. La recherche des pseudo-bases d'anthocyanidines dans les tissus végétaux. [The pseudo-bases of the anthocyanidines of plant tissues.] Compt. Rend. Acad. Sci. Paris 174: 58-61. 1922.—An attempt is made to establish the conclusion that the substances considered by Noack as pseudo-bases of anthocyanidines are really phlobatannins. The tissues employed were the leaves of *Ampelopsis hederacea*, of grapes, and of apples; also the pericarp of *Aesculus Hippocastanum*.—C. H. Farr.

2093. FÄRBER, E., und F. F. NORD. Die phytochemische Reduktion des Acetols zu optischaktivem Propylenglykol. [Phytochemical reduction of acetol to optically active propylene glycol.] Biochem. Zeitschr. 112: 313-323. 1920.—Acetol, which is optically inactive, was reduced by yeast to levorotatory propylene glycol.—H. D. Hooker, Jr.

2094. HADJOPOULOS, L. G. Complement fixation in typhoid fever. Jour. Infect. Diseases 31: 226-232. 1922.—The formation of complement-fixing bodies was observed as one of the earliest and most constant immune manifestations in the course of typhoid infection. The satisfactory application of the complement-fixation test in the diagnosis of the fever is described.—R. V. Allison.

2095. IRVINE, JAMES COLQUHOUN, and EDMUND LANGLEY HIRST. The constitution of polysaccharides. Part V. The yield of glucose from cotton cellulose. Jour. Chem. Soc. [London] 121: 1585-1591. 1922.—Careful methods, described in detail, were used, anhydrous cotton cellulose being first converted into cellulose triacetate, then into alpha- and beta-methylglucosides, then into glucose. "Considering the standard of purity in which the mixed methylglucosides were isolated, there can be no further doubt that cotton cellulose is composed entirely of glucose residues."—F. E. Denny.

2096. JOYNER, REGINALD ARTHUR. The viscosity of cellulose in cuprammonium hydroxide solution. Part I. The determination of the viscosity. Jour. Chem. Soc. [London] 121: 1511-1522. Fig. 1. 1922.—An apparatus was devised for dissolving cotton cellulose and measuring the viscosity by the falling-sphere method. Cuprammonium solutions of high cellulose-dissolving power were prepared by bubbling air through a mixture of clean copper turnings and strong ammonia. Adding about 1 gm. of sucrose per l. hastened the dissolution of the copper and protected the reagent against the loss of dissolved copper on standing. A study was made of the effect on the viscosity produced by varying the relative proportions of copper, ammonia, and cellulose. The most suitable proportion for viscosity measurements varied with the type of cotton, but for general use a solution containing 13 gm. of dissolved copper, 20 gm. of cellulose, and 200 gm. of ammonia per l. is recommended. With high copper concentration and low ammonia content cellulose is gelatinized and dissolves slowly. Large variations in viscosity values resulted from the difficulty in taking a representative sample of cotton.—F. E. Denny.

2097. OSBORNE, T. B., A. J. WAKEMAN, and C. S. LEAVENWORTH. The water-soluble constituents of the alfalfa plant. Jour. Biol. Chem. 53: 411-429. 1922.

2098. RICHARDSON, WILLIAM D. The vitamine doctrine and the oleomargarine industry. 16 p. Institute of Margarin Manufacturers: Washington, 1921.—In this paper there is presented a brief discussion of the vitamins and their occurrence. Emphasizing the variety of plant and animal products in which the fat-soluble vitamin (A) occurs, the author endeavors to show that "given an ordinary, every day, reasonable well balanced diet for the average man, woman or child, it does not make any difference from the dietary standpoint whether the individual eats oleomargarine or butter,"—B. M. Duggar.

2099. SAMEC, M., und H. HAERDTL. Studien über Pflanzenkolloide IX. Zur Kenntniss verschiedener Stärkearten. [Plant colloids IX. Starches.] Kolloidchem. Beih. 12: 281-300. 1920.—The authors used carefully prepared starches from potato, *Maranta arundinacea*, *Mannihot utilissima*, *Curcuma Zedcaria*, horse chestnut, wheat, *Oryza glutinosa*, maize, and rice, and found that all contain an electrodialytically precipitable, viscous portion that conducts electricity (A. Meyer's β -amylose; L. Maquenne's amylopectin) and a portion that is the opposite in all these respects (Maquenne's amylose). The relative amounts of these 2 are different in different starches, as are also the water content of the grain, the viscosity of the starch solution, and the rapidity with which diastase acts on the starch. All starches contain phosphorus, the variation in amount being paralleled by the electric conductivity of the electrodialyzed solution. The method of union or degree of saturation of the phosphoric acid varies, however. All starches react with alkalis and become more fluid as the temperature is raised.—H. E. Pulling.

2100. STOKLASA, J. Der Mechanismus der physiologischen Wirkung der Radiumemanation und der Radioaktivität des Kaliums auf die biochemischen Vorgänge bei den Wachstumsprocess der Pflanzen. II. [Mechanism of the action of radium and radioactive potassium on biochemical processes in plant growth.] Biochem. Zeitschr. 108: 140-172. 1920.—Under the influence of radium emanations for 5 days, 48.04 per cent of the total nitrogen was converted to amide nitrogen by proteolytic enzymes, as compared with 32.16 per cent under control conditions. Radium emanations stimulated the development and metabolism of many plants,

the dosage depending on the plant. Stimulation was produced by a weak dosage in all but potash plants, such as the sugar beet, in which growth was depressed. Tissues rich in potassium were found to be sensitive to radium emanations. This was found especially true of green tissues, etiolated leaves being deficient in potassium. The toxic action of radium is attributed to the products of augmented carbon assimilation. Radium exerted no toxic influence on the chlorophyll-free cells of bacteria, in spite of their being rich in potassium.—*H. D. Hooker, Jr.*

2101. WASICKY, RICHARD. Ein Beitrag zur Kenntnis der Rolle der Pflanzenglycoside. [The role of plant glucosides.] *Biochem. Zeitschr.* 113: 1-18. 1921.—Several samples of the isolated leaves and stems of *Digitalis purpurea* about 1 year old were placed separately in Knop's nutrient solution and in tap water. Some were exposed to sunlight and others kept in the dark for a varying period of time, at the end of which the effect produced upon glucosidal content was determined, using the biological method for assaying the digitalis glucosides. Experiments were also carried out to determine the action of the accompanying enzymes and to locate the glucosides in the leaves by microchemical reactions. The writer states that the quantity of the glucosides in digitalis follows the assimilation curve, being at its maximum at the time when assimilation is at its greatest intensity. He concludes that glucosides undoubtedly play an important part in regulating the turgidity of plant cells.—*J. M. Marañon.*

2102. HOFFMAN, WALTER FRED, and ROSS AIKEN GORTNER. Sulfur in protein 1. Effect of acid hydrolysis upon cystine. *Jour. Amer. Chem. Soc.* 44: 341-361. 1922.

2103. JONES, D. B., C. E. F. GERSDORFF, C. O. JOHNS, and A. J. FINKS. The proteins of the lima bean, *Phaseolus lunatus*. *Jour. Biol. Chem.* 53: 231-240. 1922.—The lima bean meal used yielded 21.17 per cent of protein, consisting of 2 globulins and an albumin, all 3 containing tryptophane.—*G. B. Rigg.*

2104. VICKERY, H. B. The rate of hydrolysis of wheat gliadin. *Jour. Biol. Chem.* 53: 495-511. 1922.—Acid hydrolysis of this protein is a continuous process proceeding from first to last without marked interruption due to the existence of stable complexes, and is, therefore, clearly distinguished from enzymatic hydrolysis.—*G. B. Rigg.*

2105. WARBURG, O., und E. NEGELEIN. Über die Reduktion der Salpetersäure in grünen Zellen. [Nitric acid reduction in green cells.] *Biochem. Zeitschr.* 110: 66-115. 1920.—*Chlorella pyrenoides* Chick was transferred from Knop's solution to a solution of $\frac{N}{10}$ sodium nitrate- $\frac{N}{11}$ nitric acid, and nitrate reduction was studied under thermostatic conditions. Gas exchange was measured with the Haldane apparatus and also by measuring the difference in gas pressure between 2 vessels in 1 of which the evolved CO_2 was absorbed by 5 percent KOH. A Haldane-Barcroft gas manometer was used. NH_3 was determined by Nessler's colorimetric method and HNO_2 with α -naphthylamine sulphanilic acid. Nitrate reduction occurred in the dark, the CO_2 - O_2 ratio being 1.3:2.0. CO_2 equal to the O_2 consumption resulted from respiration, the excess CO_2 being produced by nitrate reduction in decreasing amounts over several hours. NH_3 was produced simultaneously in increasing amounts until 1 molecule was produced for every 2 of CO_2 according to the reaction: $\text{HNO}_3 + \text{H}_2\text{O} + 2\text{C}$ (in organic combination) = $\text{NH}_3 + 2\text{CO}_2 + 162,000$ cal. Until this equation is reached, part of the NH_3 is thought to be assimilated. Only 30 per cent of the energy evolved is available to the cell in the form of chemical energy. Nitrate reduction was 20 times as sensitive to HCN as carbon assimilation. This is thought to indicate that the 2 processes are independent and that catalytically active heavy metals participate in nitrate reduction. 0.013 per cent phenylurethan completely inhibited carbon assimilation, reduced the formation of extra CO_2 30 per cent and stimulated respiration. At low partial pressures of O_2 nitrous acid was formed, NH_3 production was decreased in proportion, and the cells were poisoned by the nitrite and died. HCN did not depress nitrite formation. When illuminated the cells evolved $2\frac{1}{2}$ -3 times as

much extra O_2 as extra CO_2 produced in the dark, and 2-3 times as much NH_3 . The reaction never reached the equation $HNO_3 + H_2O = NH_3 + 2O_2$ as nitrogen assimilation continued uninterrupted during illumination, producing an NH_3 deficit. Illumination increased nitrogen reduction but independently of carbon assimilation. When narcotized, illuminated cells gave off extra CO_2 . The stimulating effect of light is thought to result from increased absorption of nitric acid.—*H. D. Hooker, Jr.*

METABOLISM (ENZYMES, FERMENTATION)

2106. BIJL, PAUL A. VAN DER. Studies on some fungi and the deterioration of sugar. Union South Africa Dept. Agric. Sci. Bull. 18. 19 p. 1920.—The fungi studied are *Penicillium divaricatum*, strains of the *Aspergillus repens glaucus* group, strains of the *Penicillium luteum purpurogenum* series, *Aspergillus niger*, *A. terreus*, and *A. fumigatus*. The growth of these fungi was observed in sugar solutions of different densities and studies were made of the influence of acidity or alkalinity and of chlorides upon the inversion of sucrose by fungi, the hygroscopic nature of the decomposition products of dextrose, the influence of different moisture contents on the deterioration of refined sugar infected with fungi, the effect of partial sterilization by heat, and the effect of various disinfectants on the fungi.—The normal losses due to inversion in sucrose in mills can be attributed to (1) the enzyme invertase which is normally present in cane, and (2) the enzyme secreted by various microorganisms.—The inversion of sugar by microorganisms is influenced by temperature, the moisture present in the sugar, humidity of the atmosphere, exposure to infection by microorganisms, and hygroscopic non-sucrose substances present in raw sugar. All these factors can be controlled to a large extent.—*E. M. Doidge.*

2107. DAVISON, WILBURT C. Filterable "substance" antagonistic to dysentery and other organisms (d'Herelle's phenomenon, bacteriophage, bacteriolytic agent, bacteriolysant, etc.). Absts. Bact. 6: 159-177. 1922.—This is an extensive, analytical, and critical review of the literature which deals with the d'Herelle phenomenon, namely, that Berkefeld filtrates of stool cultures and of cultures from other sources kill and dissolve dysentery bacilli and other organisms. D'Herelle's idea that this agent is the living *Bacteriophagum intestinale* is rejected and it is concluded: that the phenomenon probably depends upon a bacteriolytic enzyme produced by bacteria; that the amount of this enzyme produced by a culture can be increased by external influences; that the action of these external influences is probably to favor the development of lysogenic organisms at the expense of non-lysogenic; that this enzyme not only dissolves organisms but also favors the multiplication of bacteria which produce this enzyme; and that it is highly improbable that this phenomenon represents a defense mechanism on the part of an animal against bacterial invasion.—The publications of 32 authors are noted in the bibliography.—*D. Reddick.*

2108. EFFRONT, JEAN. Sur les propriétés distinctives des amylases de différentes provenances. [On the distinctive properties of amylases from different sources.] Compt. Rend. Acad. Sci. Paris 174: 18-21. 1922.—A new method is employed in this study, namely, the coagulation of starch by iodine. Amylases were studied from 18 sources, including human and vegetable material. They are compared as to ability to liquefy and to saccharify starch expressed as grams per hour, and also as to the intensity with which they accomplish hydrolysis in the presence of an excess of diastase after 5 hours of optimum temperature. The amylases are found to vary much in these properties. The optimum temperature for liquefaction is also highly variable. The filtration of some of the amylases is found to increase their activity, possibly due to the adherence to the filter and consequent removal of certain colloidal substances which may have a retarding effect on the reaction.—*C. H. Farr.*

2109. HAAR, A. W. VAN DER. Die Entbehrlichkeit des Mangans für das Oxydasenmolekül bei der Züchtung von *Hedera helix*, und die Bertrandsche Mangantheorie der Oxydasen. [The superfluosity of manganese in the oxydase molecule produced by *Hedera helix* in culture, and Bertrand's manganese-oxidase theory.] Biochem. Zeitschr. 113: 19-28. 1921.—

Germinating and growing *Hedera helix* in nutrient culture solutions practically free from manganese, van der Haar obtained plants containing only 0.02 mgm. of manganese in 12.4 gm. of green weight. The ungerminated seed contained 0.001 mgm. manganese per seed. The 12.4 gm. was the weight of one plant, which showed a slight increase in manganese over that found in the seed. The oxidase obtained from these plants gave all the normal reactions characteristic of oxidase from plants growing under normal conditions. The writer concludes that Bertrand's manganese theory, according to which the oxidase is a manganese protein compound, is not applicable to the *Hedera* oxidase, which he thinks is to be considered as a glucoprotein compound.—*F. G. Gustafson.*

2110. IREDALE, THOMAS. The role of protective colloids in catalysis. Part II. Jour. Chem. Soc. [London] 121: 1536-1542. 1922.—This is a study of the effect of certain colloids in inhibiting the catalytic decomposition of H_2O_2 by colloidal platinum. Effectiveness was shown to be related to the method of preparation of the inhibitor. A comparison is made of 2 solutions of gelatin of the same concentration, 1 thought to consist of a large number of small particles, the other of a small number of large particles. The latter was always less effective as an inhibitor at low concentrations (0.000005 per cent) and not always at high (0.01 per cent). The "inhibition number" was defined as "that percentage of protective colloid which is just insufficient to inhibit catalytic action." Gelatin, egg-albumin, dextrin, and starch were effective in the order named. The same order holds for the Zsigmondy-gold-number coagulation-effect, and the 2 phenomena are thought to be related to the same property—"the capacity of the protective colloid for inhibiting further adsorption."—*F. E. Denny.*

2111. KÖHLER, E. Über Fermentbildung. [Enzyme formation.] Biochem. Zeitschr. 112: 236-254. 1920.—The production of zymogen and activation to zymase in yeast are stimulated independently; 5 per cent maltose retards the former and stimulates the latter; 5 per cent sucrose, glucose or fructose stimulates the former and retards the latter. Zymogen production is thought to occur in the outermost regions of the living substance.—*H. D. Hooker, Jr.*

2112. KÖHLER, E. Untersuchungen über den Gang der alkoholischen Gärung der Hefe. [The course of alcoholic fermentation by yeast.] Biochem. Zeitschr. 108: 235-243. 1920.—The rate of fermentation was measured by counting the bubbles of gas given off per minute. The course of fermentation was found to be irregular and dependent on the concentration of sugar. Increase in the concentration of alcohol during fermentation induced smaller rhythmic fluctuations in the rate of the reaction. Retardation and stimulation are thought to alternate during the course of fermentation.—*H. D. Hooker, Jr.*

2113. KÖHLER, E. Untersuchungen über den Ablauf der alkoholischen Gärung der Hefe. II. [The course of alcoholic fermentation by yeast.] Biochem. Zeitschr. 110: 128-132. 1920.—The larger rises and falls in the curve of alcoholic fermentation in response to changes in the concentration of sugar are characterized as "zig-zag phenomena."—*H. D. Hooker, Jr.*

2114. MICHAELIS, L., und M. ROTHSTEIN. Zur Theorie der Invertasewirkung. [Theory of invertase action.] Biochem. Zeitschr. 110: 217-233. 1920.—Invertase acting on 2-40 per cent sucrose in acetate or phosphate buffer solutions of various H-ion concentrations indicated that invertase combined with 1 molecule of sucrose to form an acid with dissociation constant of 3×10^{-7} . Under the experimental conditions (low salt content of the solutions and absence of marked colloid precipitants) the acid appeared molecularly dispersed and dissociated. The undissociated molecules decomposed spontaneously into the products of the enzymatic reaction. The anions were stable. This is thought to explain the effect of pH values from 3.5 to alkalinity on invertase activity.—*H. D. Hooker, Jr.*

2115. MORAN, THOMAS, and WILLIAM CUDMORE McCULLAGH LEWIS. Studies in catalysis. Part XVI. The inversion of sucrose by hydrogen ion. Jour. Chem. Soc. [London] 121: 1613-

1624. 1922.—H-ion concentrations and inversion-velocity constants were measured. These data, together with values for the viscosity of the solution and for the osmotic and vapor pressure of sucrose, permitted the authors to suggest a mechanism of the inversion process. Two consecutive reactions are involved. The activity of the H-ion was markedly increased in the presence of sucrose.—*F. E. Denny.*

2116. NEMEC, A. *Über Urikase im Samenorganismus.* [Uricase in seed.] *Biochem. Zeitschr.* 112: 286-290. 1920.—Five gm. soy-bean meal added to 100 cc. 0.3 per cent potassium urate and 5 cc. toluol decomposed the uric acid to NH_3 and CO_2 at 35°C . The enzyme activity was greater in the presence of atmospheric O_2 .—*H. D. Hooker, Jr.*

2117. NEUBERG, C., und M. SANDBERG. *Weitere Mitteilungen über chemisch definierte Katalysatoren der alkoholischen Gärung.* [Chemically defined catalyzers of alcoholic fermentation.] *Biochem. Zeitschr.* 109: 290-329. 1920.—Experiments with 82 substances including metallic as well as organic compounds showed that all reducing substances stimulated alcoholic fermentation by living yeast cells and by enzyme preparations. This is thought to show a relation between the activation of fermentation and deoxidation.—*H. D. Hooker, Jr.*

2118. NEUBERG, C., und W. URSUM. *Die dritte Vergärungsform des Zuckers als allgemeine Folge der Dismutationswirkung anorganischer und organischer Alkalisatoren.* [The third type of sugar fermentation as a general result of "dismutation" by inorganic or organic compounds producing an alkaline reaction.] *Biochem. Zeitschr.* 110: 193-215. 1920.—Substances such as ammonium bicarbonate, potassium pyrophosphate, etc., that tend to produce an alkaline reaction in solution induced the fermentation of sucrose to acetic acid, alcohol, carbon dioxide, and glycerol.—*H. D. Hooker, Jr.*

2119. PETERSON, W. H., E. B. FRED, and J. A. ANDERSON. *The fermentation of hexoses and related compounds by certain pentose-fermenting bacteria.* *Jour. Biol. Chem.* 53: 111-123. 1922.—This new group of pentose-fermenters converts glucose, fructose, lactose, raffinose, and melezitose almost quantitatively into lactic acid.—*G. B. Rigg.*

2120. PETERSON, W. H., E. B. FRED, and E. G. SCHMIDT. *The fermentation of pentoses by molds.* *Jour. Biol. Chem.* 54: 19-34. 1922.—Twenty-five species, representing *Aspergillus*, *Penicillium*, and *Mucor*, were studied, 16 of which fermented pentoses (xylose and arabinose) with rapidity. Most of the remaining 9 cultures grew slowly, although 3 or 4 produced only a few mycelial threads. The best fermenters were found among species of *Aspergillus* and *Penicillium*, although a number of molds of these types only slowly attacked the pentoses. The *Mucors*, *Rhizopus nigricans*, and *Cunninghamella* were also found to be very slow fermenters. From these results it is suggested that pentoses might be of considerable value in the separation and classification of fungi.—*G. B. Rigg.*

2121. RONA, P. *Über die Wirksamkeit der Fermente unter abnormalen Bedingungen und über die angebliche Aldehydnatur der Enzyme.* [Enzyme activity under abnormal conditions and the reputed aldehyde character of enzymes.] *Biochem. Zeitschr.* 109: 279-289. 1920.—The enzymes pepsin, trypsin, amylase, emulsin, invertase, and maltase retained their hydrolytic activity in the presence of sodium bisulphite, hydroxylamin, benzolsulphhydroxamic acid, disodium sulphite, potassium cyanide, and phenylhydrazine,—reagents that react with aldehydes,—provided the H-ion concentration was regulated. This is thought to disprove the aldehyde character of enzymes.—*H. D. Hooker, Jr.*

Zeitschr.* 111: 115-133. 1920.—The optimum pH value of 7.3-7.5 for soy-bean urease activity was confirmed. Acceleration of urease action by blood serum occurred only in prolonged experiments. No acceleration by amino-acids or retardation by H_2O or NaCl was detected. Inhibition of urease and lipase by various arsenic compounds was investigated.—*H. D. Hooker, Jr.*

ORGANISM AS A WHOLE

2123. FITCH, C. P. The cultivation of *Bacterium abortus* Bang. Jour. Infect. Diseases 31: 233-236. 1922.—The use of horse serum-beef infusion agar with a pH of 6.8-7.2 and an atmosphere of 10 per cent CO₂ or H₂ is described as giving most satisfactory results in the cultivation of this organism.—R. V. Allison.

2124. GALE, G. W. A preliminary account of some investigations on leaf-aeration in certain Natal plants. South African Jour. Sci. 18: 153-155. 1921.—The quantitative results given illustrate and confirm an important ecological principle, namely, that pioneer types are more variable in their physiological functions than subsequent types, and for that reason able to adapt themselves to the more varied conditions presented by the habitat during early stages in plant succession.—E. P. Phillips.

2125. LOTKA, ALFRED J. Contribution to the energetics of evolution. Proc. Nation. Acad. Sci. [U. S. A.] 8: 147-151. 1922.—“In every instance considered, natural selection will so operate as to increase the total mass of the organic system, to increase the rate of circulation of matter through the system, and to increase the total energy flux through the system, so long as there is presented an unutilized residue of matter and available energy.” Evolution tends to produce a maximum energy flux, provided the hereditary variations available for selection include some that tend toward increase of energy flux.—Howard B. Frost.

2126. LOTKA, ALFRED J. Natural selection as a physical principle. Proc. Nation. Acad. Sci. [U. S. A.] 8: 151-154. 1922.—The 1st and 2nd laws of thermodynamics do not, in general, completely determine the course of physical events, either in the presence or in the absence of life. Other principles must be added to explain fully what really occurs. One such principle is that of natural selection, or of “the persistence of stable forms.” The units of organic evolution are “energy transformers subject to irreversible collisions of peculiar type—collisions in which trigger action is a dominant feature.” Natural selection “functions, as it were, as a 3rd law of thermodynamics (or a 4th, if the 3rd place be given to the Nernst principle).” —Howard B. Frost.

2127. PEROTTI, R. Per la conoscenza dei rapporti fra microrganismi e pianta verde. [The relation between microorganisms and higher plants.] [Abstract.] Boll. Mens. R. Staz. Patol. Veg. 2: 96-99. 1921.

2128. VERZAR, F., und J. BÖGEL. Weitere Untersuchungen über Stoffwechselregulierung bei Bakterien. [Regulation of metabolism in bacteria.] Biochem. Zeitschr. 108: 207-219. 1920.—*Bacillus coli communis*, *B. paratyphi* B, and *B. proteus* X19 produced maximum acidity in 1 per cent glucose. At lower concentrations alkali formation followed the initial acid production. The titratable acidity at the above mentioned maximum and the threshold concentration at which alkali formation began were highest in *B. coli*. *Streptococcus haemolyticus* never produced alkali. The ultimate acidity was independent of the initial reaction. Gas formation was synchronous with acid production in *B. coli*; oxygen consumption as measured by Bancroft's apparatus was greater during alkali formation. No connection was found between movement and gas formation in *B. paratyphi*. Ethyl and methyl alcohol, chloroform, and formaldehyde retarded gas exchange in *B. coli* at concentrations much below the inhibiting dose. The toxicity of the alcohols was peculiar in that it was summated with that of the acids formed from glucose, so that a lower maximum acidity was reached in the presence of alcohol. Methyl alcohol was less toxic than ethyl.—II. D. Hooker, Jr.

GROWTH, DEVELOPMENT

2129. BROWN, WILLIAM. On the germination of fungi at various temperatures and in various concentrations of oxygen and of carbon dioxide. Ann. Botany 36: 257-283. 4 fig. 1922.—This paper describes experiments which had for their object the examination of the

behavior of certain storage rot fungi under the conditions prevailing in the practice of fruit storage. The fungi used were: *Botrytis cinerea*, *B. parasitica*, *Mucor* sp., *Rhizopus nigricans*, *Penicillium glaucum*, *Monilia cinerea*, *Fusarium* sp., *Phoma roseola*, *Alternaria Grossulariae*, and *Sphaeropsis malorum*. A series of experiments was first carried out dealing with the effect on germination of various concentrations of CO₂ and O₂. It was found that within wide limits O₂ had little effect on the germination and growth of these fungi. The latter processes were retarded by CO₂ and this retardation was more marked the lower the temperature and the weaker the nutrient in which the fungus spores were sown, and, to a less degree, it was more marked the greater the density of the medium. The author discusses the practical considerations which arise from his work. He concludes that the experimental results indicate that the gas storage method is most effectively used in combination with the ordinary cold storage method, and that it will give the best results when no attack of the fruit has begun previous to storage, and when conditions are such that a minimum of nutrients is available to fungous spores on the surface of the fruit. A review is given of the most recent and important papers dealing with the effect of temperatures on the growth of fruit-rot organisms.—W. P. Fraser.

2130. RIPPEL, AUGUST. Über die Wachstumskurve der Pflanzen. [Regarding the growth curves of plants.] Landw. Versuchssta. 97: 357-380. 1921.—This is a further discussion [see Bot. Absts. 9, Entry 519] of the applicability of the growth curves of Robertson and Mitscherlich [see Bot. Absts. 9, Entries 517, 518].—B. M. Duggar.

MOVEMENTS OF GROWTH AND TURGOR CHANGES

2131. ZAEFFEL, EDGAR. Sur le mécanisme de l'orientation des feuilles. [On the mechanism of orientation of leaves.] Compt. Rend. Acad. Sci. Paris 174: 119-120. 1922.—By splitting the petiole lengthwise and noting the curvature and torsion of the half petiole in either air or water, it is concluded that the petiole adjusts the orientation of the blade by differences in the water content of the various parts.—C. H. Farr.

GERMINATION, RENEWAL OF ACTIVITY

2132. LESAGE, PIERRE. Sur la détermination de la faculté germinative autrement que par la germination des graines. [The determination of the germinating power of seed in some other way than by germinating them.] Compt. Rend. Acad. Sci. Paris 174: 766-767. 1922.—The viability, that is the germinating power, of the seeds of *Lepidium sativum*, it was found, can be determined by the use of 20 different solutions of potash. Those seeds which become colored in a 2⁻⁵N to $\frac{1}{2}$ 2⁻⁹N solution will not germinate. Those which remain uncolored in these solutions are viable and will germinate. The color appears within 4 hours.—C. H. Farr.

2133. NEMEC, ANTONIN, et FRANTISEK DUCHON. Sur une méthode indicatrice permettant d'évaluer la vitalité des semences par voie biochimique. [A biochemical method permitting the evaluation of the viability of seed.] Compt. Rend. Acad. Sci. Paris 174: 632-634. 1922.—The method consists in determining the activity of the catalase. This is accomplished by finding the amount of O₂ liberated from H₂O₂. This is found to be in direct proportion to the germinating power. Oats which will not germinate at all may liberate as low as 4.1; those which have 100 per cent germination liberate about 78.6; and those with 66 per cent germination liberate 57.1. The same is true with peas, although in this case the proportion corresponds even more closely than with oats.—C. H. Farr.

RADIANT ENERGY RELATIONS

2134. GORIS, A., et H. DELUARD. Influence des radiations solaires sur la culture de la belladone et la formation des alcaloïdes dans les feuilles. [The influence of solar radiations on the culture of belladonna and the formation of alkaloids in leaves.] Compt. Rend. Acad. Sci. Paris 174: 188-190. 1922.—Experiments were run in triplicate. Set A, in the sunlight, continuously yielded 0.65 per cent alkaloid for the 1st crop and 0.52 per cent for the 2nd. Set B, in the shade for 6 weeks, and in the sun for 6 weeks, yielded only 1 crop of 0.42 per cent.

Set C, in the shade throughout the growing season, yielded nearly as much as B. It is concluded that plants growing in the sun will furnish 7-8 times the amount of alkaloid as those grown in the shade.—*C. H. Farr.*

TOXIC AGENTS

2135. ACEL, D. Über die oligodynamische Wirkung der Metalle. [The oligodynamic action of metals.] *Biochem. Zeitschr.* 112: 23-26. 1920.—The oligodynamic action of water in contact with metallic silver was shown to be due to the presence of silver compounds in solution which formed silver sulphide with ammonium sulphide after evaporation of the water. Water treated with ammonium sulphide lost its oligodynamic properties.—*H. D. Hooker, Jr.*

2136. CONOVER, JOHN R. The determination of the value of certain soaps in disinfecting wall and floor surfaces. *Amer. Jour. Public Health* 12: 602-605. 1922.

2137. DOERR, R. Zur Oligodynamie des Silbers. II. [Oligodynamics of silver.] *Biochem. Zeitschr.* 107: 207-218. 1920.—The bactericidal action of metallic silver was destroyed by previous heating of the metal, by repeated boiling in distilled water, or by prolonged imbedding in agar. It was reactivated by contact with strongly dissociated acids in dilute solution. The oligodynamic chemical was dialyzable, though at a different rate from silver oxide under certain conditions. No such difference was observed in the diffusibility through agar. In agar, the sterile zone about metallic silver, or silver oxide or nitrate, was surrounded by 2 concentric rings where bacterial colonies developed to unusual size. Similar zones (hemolytic) occurred about silver in blood-agar and this action could be destroyed by the same means as the bactericidal action, which is thought to be due to water-soluble silver compounds formed at the surface of the metal.—*H. D. Hooker, Jr.*

2138. DOERR, R. Zur Oligodynamie des Silbers. III. Mitteilung. [The oligodynamics of silver. III.] *Biochem. Zeitschr.* 113: 58-69. 1921.—On heating metallic silver until the edges begin to melt it loses its bactericidal property. On remaining in air this toxic property is regained, but not if kept under liquid paraffin. By further experiments the writer shows that a given area of metallic silver possesses a definite amount of toxic substance, and that if this is dissolved the silver is no longer toxic until the metal again has been exposed to air for some time. Thus an area of 200 square cm. gives off twice as much toxic substance as does an area of 100 square cm. From these experiments the writer draws the conclusion that the silver as such is not the toxic substance (oligodynamic property), but that the bactericidal property or substance is a soluble compound of silver formed in the presence of air, probably Ag_2O . In still further experiments the writer found that typhus bacteria were less influenced by the bactericidal action of silver than were the coli bacteria. Thus when grown on a solid medium with a piece of imbedded metallic silver an area 1.5 mm. wide surrounding the silver remained free from bacteria; in the next 1.5 mm.-zone there were only typhus bacteria; beyond this both typhus and the coli bacteria grew. By adding milk sugar to the agar this condition was further emphasized. Paratyphus bacteria of group A or B behaved like the typhus bacteria. The author thinks that by further work a method for separating these as well as other bacteria might be developed.—*F. G. Gustafson.*

2139. JACKSON, LLOYD E. The bacterial action of dry cleaning. *Amer. Jour. Public Health* 12: 507-509. 1922.—The "dry-cleaning" process, when properly conducted, has a very high and hygienically satisfactory bactericidal efficiency.—*C. A. Ludwig.*

2140. JULIANELLE, LOUIS A. Studies of hemolytic staphylococci. *Jour. Infect. Diseases* 31: 256-284. 1922.—Staphylococci were observed to produce a hemolytic substance in broth about the 6th day with a maximum at the 9th or 10th, disappearing on the 13th to 16th day. The nature and activity of the substance is described and it is thought to be associated with proteolysis and perhaps autolysis.—*R. V. Allison.*

2141. KAPPEN, H. **Über die Aziditätsformen des Bodens und ihre pflanzenphysiologische Bedeutung.** [The forms of soil acidity and their significance in relation to plant physiology.] Landw. Versuchssta. 96: 277-307. 1920.—The author discusses 3 characteristic forms of soil acidity. The 1st is exhibited by merely shaking the soil with water and determining the acid content by titration. This is due to free acids and acid salts. The 2nd is that type obtained by treating the soil with solutions of true neutral salts. This was originally taken to indicate the existence of humic acids but it is now known that such acidity is in part due to the occurrence of mineral acids in the extract. This phenomenon is now explained by adsorption or ion exchange, resulting from the interchange of ions between the neutral salts and certain aluminium and iron compounds which exist as colloidal constituents of the soil. The 3rd form of acidity is that induced by the capacity of the soil to dissociate such salts as consist of a strong base and a weak acid. The salts of this nature are characterized by hydrolysis in water. In the soil a part of the base is adsorbed and the corresponding acid is set free. This can be designated hydrolytic acidity. Throughout the paper the relation of humus type and content to the production of acidity is discussed, in particular the physiological significance of the 3rd form of acidity. In general the latter is considered to be uninjurious. With special reference to the importance of humic acids in respect to the growing plant, it is stated that the low solubility of these substances renders them of little consequence in soil acidity. They constitute, therefore, an extremely small part of the 1st form of acidity and likewise of the 2nd type, since in the latter case these acids do not affect neutral salts. In consequence, humic acids may be considered only in the 3rd category of acidity, that is, with hydrolytic acidity, in which category, however, they may not be regarded as injurious to plant growth. In the application of lime to soil it is held that the least effect is that of its action upon the humic acids.—B. M. Duggar.

2142. MACINNES, JEAN. **The growth of the wheat scab organism in relation to hydrogen ion concentration.** Phytopathology 12: 290-294. Fig. 1. 1922.—A species of *Fusarium* isolated from scabby wheat was grown in a modified Czapek's solution plus a mixed buffer solution. The H-ion concentration was varied by the addition of increasing amounts of NaOH. The organism grew at all concentrations between pH 3 and pH 11.7. This range is decidedly wider than for any fungus previously studied; and, considering the large number of hosts attacked by this fungus, its tolerance of acid and alkaline media may be significant.—B. B. Higgins.

2143. PLANTEFOL, L. **Sur le toxicité de divers phénols nitrés pour le *Sterigmatocystis nigra*.** [The toxicity of various nitrogenous phenols towards *Sterigmatocystis nigra*.] Compt. Rend. Acad. Sci. Paris 174: 123-126. 1922.—A study is reported on the germination and growth of *Sterigmatocystis nigra* in ortho-, meta-, para nitrophenol; 1, 2, 4—dinitrophenol; and 1, 2, 4, 6-trinitrophenol. It is found that the nitrophenols are more toxic than phenol. The ortho-mononitrophenol is the least toxic of the mono- group; and the para- is the most toxic. The dinitrophenol is much more toxic than any of the mono- types. The trinitrophenol has a degree of toxicity like the mono- compounds.—C. H. Farr.

2144. PLOTHO, O. VON. **Der Einfluss der kolloidalen Metallösungen nach Übertragung des Pilzmycels aus verschiedenen Nährsubstraten.** [The influence of metals in colloidal solution after transfer of the mycelium from various nutrient solutions.] Biochem. Zeitschr. 110: 33-59. 1920.—The fixation of colloidal metals by the plant membrane occurred in the absence of organic colloids, but when the amount was insufficient to prevent all fixation, storage of the metal was inversely proportional to the amount of organic colloid. Since gold could be prepared in colloid solution without organic protective colloids, gold storage readily occurred. Silver and copper required protective colloids and in undiluted solutions there was no fixation. On dilution the degree of protection was reduced and eventually some silver and copper fixation occurred. Storage occurred when the charge on the membrane particles was positive, as in acid solution, the charge on the particles of colloidal metal being negative under all conditions. Hence, storage was possible only by those organisms that tended to

make the solution acid. By regulating the acidity of the hydrosol, storage could be regulated. Retardation of growth never occurred in colloidal gold solutions, but it appeared in colloidal silver and copper solutions and the smaller the colloid particles the greater the retardation. The resistance of the organisms varied, being less in *Aspergillus* than in other fungi and greater in *Bacillus Brassicae* than in *B. megatherium*. The toxicity of silver and copper was evident in delayed germination and conidia development, in swellings of the membrane, in the development of giant cells, in bendings and thickenings of the mycelium and of the membrane, and in modification of the conidiophores.—*H. D. Hooker, Jr.*

2145. RONA, P., und H. PETOW. Beiträge zum Studium der Giftwirkung. Versuche über die Giftwirkung des Thiodiglykols und seine Derivate an Sojabohnenurease. [The toxic action of thiodiglycol and its derivatives on soy-bean urease.] Biochem. Zeitschr. 111: 143-165. 1920.—Thiodiglycol was not toxic to urease. Thiodiglycol acetate and sulphonate do not affect the H-ion concentration; the former is not toxic, the latter is to a moderate degree. The dichlordiethyl sulphide increases the H-ion concentration and completely inhibits urease activity when present in small amounts. It retards urease activity slightly when the H-ion concentration is regulated. The tetrachlordiethyl sulphide increases H-ion concentration and inhibits urease activity even when the reaction is regulated.—*H. D. Hooker, Jr.*

2146. SCHNABEL, A. Über die Bestimmung zell- und keimschädigender Substanzen in dünnen Lösungen auf biologischem Wege. (I. Mitteilung: Optochin.) [Biological determination of optochin in dilute solutions.] Biochem. Zeitschr. 108: 258-278. 1920.—One part of optochin in a million or more could be determined by the effect on the reduction of methylene blue by pneumococci. The ultimate dilution that could be determined was a function of time, temperature, and number of bacteria. At room temperature 1 part in a billion could be detected qualitatively. Quantitative data were best obtained at 37°C.—*H. D. Hooker, Jr.*

2147. WALKER, W. F. The treatment of swimming pool water with ultraviolet rays. Amer. Jour. Public Health 12: 320-325. 1922.—Ultraviolet rays proved effective for keeping bacterial contamination in a swimming pool reduced to a low point.—*C. A. Ludwig.*

ELECTRICITY AND MECHANICAL AGENTS

2148. SZENT-GYÖRGYI, A. VON. Kataphoreseversuche an Kleinlebewesen. Studien über Eiweissreaktionen. III. [Cataphoresis experiments on micro-organisms. Studies on protein reaction. III.] Biochem. Zeitschr. 113: 29-35. 1921.—The writer found that in general bacteria migrated toward the anode, while some trypanosomes migrated toward the anode and others toward the cathode. He found that morphologically there is no difference between organisms that migrate to opposite poles. In these experiments the writer used a potential difference of 100 volts, the organisms being suspended in isotonic sugar solution, Ringer's solution (without the bicarbonate), or in a mixture of 3:1 of the 2. All solutions were kept at pH 7.0 (regulated with phosphate buffers).—*F. G. Gustafson.*

SOIL SCIENCE

A. G. McCall, *Editor*

(See also in this issue Entries 1534, 1542, 1543, 1545, 1554, 1560, 1567, 1569, 1570, 1571, 1591, 1592, 1593, 1594, 1595, 1596, 1608, 1611, 1723, 1725, 1836, 1840, 1843, 1878, 1891, 1910, 2082)

2152. ANONYMOUS. An outline of the uses of lime. Nation. Lime Assoc. Pamphlet 251. 8 p. 1922.

2153. ANONYMOUS. Eine einfache Methode zur Bestimmung des Säuregrades in Boden. [A simple method for determining the acidity of soils.] Mitteil. Deutsch. Landw. Ges. 37: 461-462. 1922.—A paper (title not given) by J. HISSINK, in Veldbode No. 1018, is reviewed. The work of Hissink was based on the method of Comber described in Jour. Agric. Sci. 10: 420-424. 1920.—A. J. Pieters.

2154. ANONYMOUS. Recent changes in artificial fertilizers. Agric. Gaz. New South Wales 33: 629-630. 1922.—The article discusses production changes which have come about during the past several years. These are most noticeable among nitrogenous fertilizers. Of these there are at least 7 recent kinds and much experimental work is necessary before these fertilizers can be used to best advantage.—L. R. Waldron.

2155. ANONYMOUS. The living soil. [Rev. of: FRANCÉ, R. H. Das Edaphon. Untersuchungen zur Ökologie der bodenbewohnenden Mikroorganismen. (Ecology of soil organisms.) 99 p. Franck'sche Verlagsbuchhandlung: Stuttgart, 1921.] Nature 110: 206-207. 1922.—The author coined the term "Edaphon" to cover all forms of life in the soil. He has performed a real service in bringing together scattered material, but has omitted reference to much recent work and perhaps over-emphasized the importance of soil organisms.—O. A. Stevens.

2156. BRAUND, H. J. The soils of the Murrumbidgee irrigation areas. How to develop their capacity for fruit production. Agric. Gaz. New South Wales 33: 631-638. 1922.—The physical structure of the soil is discussed and the total amount of plant food per acre to a depth of 4 feet is given. It is pointed out that when physical and chemical conditions in a soil are favorable for optimum plant growth, the biological factor readily adjusts itself. In certain of these soils it was found that the sub-strata were of single grain formation, preventing proper root penetration. Suggested methods for bringing about a crumb structure of soil in the sub-soil are discussed. Growing *Melilotus alba* in conjunction with deep application of gypsum is the method recommended.—L. R. Waldron.

2157. DEUSS, J. J. B. Groenbemesters in theetuinien. [Green manures in tea gardens.] De Thee 2: 50-51. 1921.—The tea experiment station in Java has recommended the planting of legumes in the tea gardens, but the planters have been slow to accept the idea. Experience with *Tephrosia* for soil improvement and partial control of weed grasses is described. If the legume is properly placed and pruned it does not suppress the tea.—Carl Hartley.

2158. DEUSS, J. J. B. Uitwassching en kalkbemesting. [Leaching and lime fertilizing.] De Thee 1: 107-109. 1920.—The author expresses disapproval of a proposal to dig catch basins in tea gardens to decrease erosion. In the tea regions of West Java the rainfall exceeds evaporation. There is too much tendency to leaching, even soils on limestone being deficient in the lime required for the best development of tea. A system should be used which takes off surplus rainwater, rather than one that retains it.—Carl Hartley.

2159. DEUSS, J. J. B. Zand-, leem- en kleigronden. [Sand, loam, and clay soils.] De Thee 2: 48-50. 1921.—A popular discussion is presented of the distinguishing characters of these soil types. Java tea is mainly grown on loam, the clay soils giving poor results.—Carl Hartley.

2160. GUTHRIE, F. B. The tick bean as green-manure. *Agric. Gaz. New South Wales* 33: 751. 1922.—An analysis of tick bean (*Vicia faba*) grown under irrigation showed that 98 pounds of nitrogen, 26 of phosphoric acid, and 127 of potash are added to each acre of soil when the crop is plowed under green.—*L. R. Waldron*.

2161. HUDIG, J., en C. MEIJER. De beteekenis van "Tetrafosfaat" als meststof. [The importance of tetraphosphate as fertilizer.] *Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefsta.* 25: 140-159. *Pl.* 1-8. 1921.—This fertilizer is made from natural phosphates by crushing and heating. From experimental results the following conclusions are drawn: The tetraphosphate functioned best on acid soils but very seldom surpassed superphosphate. Whenever it gave better results it was due to a greater acidity of the soil not favorable for superphosphate. Some acid soils in Netherlands (mostly sand) can be fertilized to advantage with either tetraphosphate or natural phosphates.—*Peter J. Klaphaak*.

2162. KUFFNER, KARL. Zur Phosphorsäurefrage. [On the question of phosphoric acid.] *Mitteil. Deutsch. Landw. Ges.* 37: 512-513. 1922.—The author points out that on some soils, rich in phosphate plants may suffer from phosphate hunger. He gives some data to show that such cases occur when the ratio of magnesium to calcium is wider than 1 to 2.5. When calcium exceeds this proportionate amount the phosphate combines into the insoluble tricalcium phosphate.—*A. J. Pieters*.

2163. LIGTENBERG, J. F. Grondwaterstand, capillariteit en verdamping. [Height of ground water, capillarity, and transpiration.] *Cultura* 34: 262-270. 1922.—A general consideration of the physics of the soil as worked out by Wollny, King, Versluijs, and others is presented. The writer brings together these results as well as his own in connection with the future relation of the IJssel Lake to the height of the ground water of the province of Friesland.—*J. C. Th. Uphof*.

2164. NOSTITZ, A. Über die Bedeutung des austauschbaren Bodenkalkiums für die Pflanzenernährung. [The meaning of exchangeable soil potash in plant nutrition.] *Jour. Landw.* 70: 45-72. 1920.—An experiment with Rothenburger, Bayreuther, and Augsburg soils is reported.—*F. M. Schertz*.

2165. OSUGI, S., and N. SOYAMA. On the change of soil-reaction by manuring. *Ber. Ohara Inst. Landw. Forsch.* 2: 79-93. 1921.—A progress report is made on the effect of various fertilizers on the H-ion concentration of field soils on which barley and rice were grown. The effect of the alkaline reaction of lime, lime-nitrogen, and wood ashes on the barley soil was distinct. The soil from the paddy rice field showed an alkaline reaction which resembled that of the irrigation water.—*H. S. Reed*.

2166. PETIT, A. A propos du "reveil de la terre arable." [Concerning the washing of fertile soil.] *Compt. Rend. Acad. Sci. Paris* 174: 1033-1034. 1922.—A summary is made of an article published by the author in 1909, in which data were presented which have been more recently confirmed by Lumière [see *Bot. Absts.* 11, Entry 3153]. A beneficial effect upon seed germination is indicated following washing the soil with distilled water.—*C. H. Farr*.

2167. VEIL, C. Relation entre l'indice de chlore et la teneur en azote de la terre végétale. [The relation between the index of chlorine and the nitrogen content of the soil.] *Compt. Rend. Acad. Sci. Paris* 174: 317-319. 1922.—The author reports a study to determine with what precision the nitrogen content of the soil can be determined by the loss of active chlorine from sodium hypochloride. Tests were made with various soils from 5 localities. A soil rich in nitrogen has a high chlorine index. In very rich soils in which the nitrogen content was found to be higher than 0.4 per cent the chlorine index ran higher than 30. In poor soils with a nitrogen content of less than 0.1 per cent, the chlorine index is 7-12. If the nitrogen content is between 0.1 and 0.2 per cent the chlorine index is 15-17.—*C. H. Farr*.

2168. WILLIAMS, C. O. Apparent infertility of the soil around trees. Jour. Dept. Agric. Union South Africa 5: 254-258. 1922.—From experiments carried out to test the moisture content of the soil around trees the conclusion is drawn that the apparent infertility is due to the absorption of the moisture by the ramified roots of the trees.—*L. J. Goldblatt.*

TAXONOMY OF VASCULAR PLANTS

J. M. GREENMAN, *Editor*

E. B. PAYSON, *Assistant Editor*

(See also in this issue Entries 1532, 1599, 1635, 1647, 1652, 1679, 1725, 1749, 1863, 1894, 1909, 1947, 2070)

GENERAL

2169. HAINES, H. H. The botany of Bihar and Orissa. An account of all the known indigenous plants of the province and of the most important or most commonly cultivated exotic ones. Gamopetalae. Part IV. *Small 8vo*, p. 419-754. Adlard & Son & West Newman: London, 1922.—This part follows strictly the plan of previously issued parts of the work and includes the families Rubiaceae to Labiatae, arranged essentially in the sequence of Bentham and Hooker's Genera Plantarum. The following apparently new names and combinations are included: *Gardenia gummifera* L.f. var. *gummiferoides*, *Blumea atropurpurea*, *B. lacera* DC. var. *erianthoides*, *Spilanthes acmella* L. var. *typica*, *Sonchus arvensis* L. vars. *typica* and *glaber*, *Lobelia zeylanica* L. var. *aligera* (*L. aligera* Haines), *Mimusops hezandra* Roxb. vars. *typica* and *orizensis*, *Diospyros sylvatica* Roxb. var. *latifolia*, *Carissa paucinervia* A. DC. vars. *opaca* Stapf and *gangetica* Stapf, *C. spinarum* L. vars. *diffusa* and *scandens*, *C. inermis* Vahl var. *Dalzellii*, *Swertia angustifolia* Ham. var. *pyramidalis*, *Hydrolea zeylanica* Vahl vars. *erecta* and *diffusa*, *Ipomoea hastata* (*Merremia hastata* Hallier), *I. caespitosa*, *I. cymosa* R. & S. var. *cochleata*, *I. turpethum* Br. var. *humilior*, *Convolvulus paniculatus* (*Ipomoea paniculata* Burm.), *Datura Stramonium* L. var. *Wallichii* (*D. Wallichii* Dunal), *Limnophila hirsuta* Benth. var. *Clarkei*, *Vandellia crustacea* Benth. var. *verticillata*, *V. brachiata* (*Bonnaya brachiata* Link & Otto), *V. veronicaefolia* (*Bonnaya veronicaefolia* Spreng.), *V. verbenaeefolia* (*Bonnaya verbenaeefolia* Spreng.), *V. oppositifolia* (*Bonnaya oppositifolia* Spreng.), *V. tenuifolia* (*Bonnaya tenuifolia* Spreng.), *Lindernia parviflora* (*Ilysanthes parviflora* Benth.), *L. hyssopioides* (*Ilysanthes hyssopioides* Benth.), *Didissandra lanuginosa* Clarke var. *minuta*, *Tecoma stans* (L.) Juss. var. *apiifolia*, *Stereospermum angustifolium* (*S. chelonoides* var. *angustifolium* Haines), *S. chelonoides* (*Bignonia chelonoides* L. f.), *Dolichandrone falcata* Seem. var. *Lawii* (*D. Lawii* Seem.), *Barleria cristata* L. var. *albida*, *Premna flavescens* Ham. var. *gmelinoides*, *P. latifolia* Roxb. var. *Gamblei* (*P. integrifolia* Gamble), *Orthosiphon grandiflorus* (*Ocimum grandiflorum* Blume), *Nepeta hindostana* (*Glechoma hindostana* Roth), and *Leucas montana* Spreng. vars. *mollissima*, *pilosa* (*L. pilosa* var. *pubescens* Benth.), and *parvifolia*.—*J. M. Greenman.*

2170. RYDBERG, PER AXEL. Ambrosiaceae. North Amer. Flora 33: 3-44. 1922.—The author treats the genera *Iva*, *Leuciva*, *Oxytenia*, *Chorisiva*, *Cyclachaena*, *Euphrosyne*, *Dicoria*, *Hymenoclea*, *Ambrosia*, *Acanthambrosia*, *Franseria*, and *Xanthium* as a distinct family of the Carduales. Generic and specific characterizations are given together with a complete citation of synonymy, statement of the type locality, and distribution of the species. The following new genera, new combinations, and new species occur: *Leuciva* n. gen. *L. dealbata* (*Iva dealbata* Gray), *Chorisiva* n. gen., *C. nevadensis* (*Iva nevadensis* M. E. Jones), *Cyclachaena pedicellata*, *C. lobata*, *Dicoria oblongifolia*, *D. hispidula*, *Hymenoclea pentalepis*, *Ambrosia monophylla* (*Iva monophylla* Walt.), *A. diversifolia* (*A. artemisiifolia diversifolia* Piper), *A. Rugelii*, *A. californica*, *Acanthambrosia* n. gen., *A. Bryantii* (*Franseria Bryantii* Curran), *Franseria Palmeri*, *F. villosa* (*F. bipinnatifida villosa* Eastw.), *F. linearis* (*Gaertneria linearis* Rydb.), *F. canescens* (*Ambrosia fruticosa* var. *canescens* Benth.), *F. strigulosa*, *F. confertiflora* (*Ambrosia confertiflora* DC.), *F. Pringlei*, *F. caudata*, *F. hispidissima*, *F. incana*, *F. leptophylla* (*F. camphorata* var. *leptophylla* Gray), *F. intricata*, *F. malvacea*, *F. Sanctae-Gertrudis*, and *F. lancifolia*.—*E. B. Payson.*

2171. RYDBERG, PER AXEL. *Carduaceae*. North Amer. Flora 33: 45-46. 1922.—In the present part of volume 33 Rydberg commences the treatment of the family *Carduaceae* with a characterization of the family as a whole and the presentation of a key to the 17 tribes into which he separates the family. The first tribe, the *Vernonieae*, is elaborated by GLEASON.—E. B. Payson.

PTERIDOPHYTES

2172. DEAM, C. C. Is *Botrychum dissectum* a sterile mutant? Amer. Fern Jour. 11: 114. March 31, 1922.

2173. FERNALD, M. L. *Polypodium virginianum* and *P. vulgare*. Rhodora 24: 125-142. 1922.—Detailed study of the American plants leads to the conclusion that the plant of eastern America which has long passed as *Polypodium vulgare* is a distinct species, *P. virginianum* L., which reappears in eastern Asia, while the plants of the Pacific slope which have been known as *P. californicum* Kaulf., *P. intermedium* Hook. & Arn., *P. falcatum* Kellogg, and *P. hesperium* Maxon are an intergradient series with all the specific characters of the European *P. vulgare*. The following new names occur: *P. vulgare* var. *intermedium* (Hook. & Arn.) n. comb. based on *P. intermedium* Hook. & Arn., var. *intermedium* forma *projectum* n. f., var. *Kaulfussii* (D. C. Eaton) n. comb. based on *P. californicum* var. *Kaulfussii* D. C. Eaton; and under *P. virginianum* forma *acuminatum* (Gilbert) n. comb. based on *P. vulgare acuminatum* Gilbert, forma *elongatum* (Jewell) n. comb. based on *P. vulgare* forma *elongatum* Jewell, forma *brachypterum* (Ridlon) n. comb. based on *P. vulgare* forma *brachypterum* Ridlon, forma *subsimplex* n. f., forma *deltoideum* (Gilbert) n. comb. based on *P. vulgare* forma *deltoideum* Gilbert, forma *bipinnatifidum* n. f., forma *chondroides* n. nom. for *P. vulgare* var. *bifido-multifidum* Gilbert not Druery, forma *alato-multifidum* (Gilbert) n. comb. based on *P. vulgare* var. *alato-multifidum* Gilbert, and forma *Churchiae* (Gilbert) n. comb. based on *P. vulgare* var. *Churchiae* Gilbert.—M. L. Fernald.

2174. HOPKINS, L. S. Is *Botrychum dissectum* a sterile mutant? Amer. Fern Jour. 11: 114-116. March 31, 1922.

2175. MAXON, WILLIAM R. Notes on American ferns—XVIII. Amer. Fern Jour. 11: 105-107. March 31, 1922.—Range is extended for 4 species; and a note is given on the reported hybrid between *Polystichum acrostichoides* (Michx.) Schott and *Dryopteris cristata* (L.) Gray, which seems to be only an extreme form of *Polystichum acrostichoides* (Michx.) Schott.—F. C. Anderson.

2176. MAXON, WILLIAM R. Studies of tropical American ferns—No. 7. Contrib. U. S. Nation. Herb. 24: 33-63. Pl. 11-20. 1922.—This paper consists of studies of various small groups of tropical American ferns. A revision of the North American species of *Alsophila* grouped with *A. armata* contains a key to 13 species, with full descriptions and synonymy. *A. strigillosa* (Cuba), *A. notabilis* (Cocos Island), *A. pansamalana* (Guatemala), *A. nesiotica* (Cocos Island), and *A. trichiata* (Costa Rica and Panama) are new. A new *Alsophila*, *A. Williamsii* from Panama, of another group, is also described. The following new names and new species appear under *Dicranopteris*: *D. affinis* (Mett.), *D. Brittonii* (from Trinidad), *D. gracilis* (Mart.), *D. longipes* (Fée), *D. longipinnata* (Hook.), *D. maritima* (Hieron.), *D. nervosa* (Kaulf.), *D. nuda* (Moritz), *D. pennigera* (Mart.), *D. pruinosa* (Mart.), *D. remota* (Kaulf.), *D. rubiginosa* (Mett.), *D. simplex* (Desv.), *D. velata* (Kunze), *D. yungensis* (Rosenst.). A key to the 4 species of *Cheilanthes* known from Jamaica is given. Two, *C. Harrisii* and *C. jamaicensis*, are new. *Polystichum deminuens*, from Cuba, and *P. Killipii*, from Jamaica, are described as new. *Atalopteris* Maxon & C. Chr. n. gen., based on 2 species heretofore referred to *Psomiocharpa*, is described and discussed, and a key is given to the 2 known species, *A. aspidioides* (Griseb.) Maxon & C. Chr., from Cuba, and *A. Maxoni* (Christ) C. Chr., from Jamaica. Three new species of the subgenus *Stigmatopteris* of *Dryopteris* are described: *D. nothochlaena*, from Jamaica, *D. hemiptera*, from Cuba, and *D. sordida*, from Guatemala.

Under miscellaneous notes, various range extensions are listed, and new combinations and names are made as follows: *Pityrogramma schizophylla* (Baker), *P. Eggersii* (Christ), and *Dryopteris anceps* (*Acrostichum Fendleri* Baker). . Ten of the species described in this paper are illustrated by photographic plates.—S. F. Blake.

2177. WEATHERBY, C. A. The group of *Polypodium lanceolatum* in North America. Contrib. Gray Herb. 65: 3-14. 1922.—As here understood *P. lanceolatum* is a species of wide distribution in tropical regions of America, Africa, and India and in its main distinguishing characters it is constant enough throughout its range, but in certain other characters, notably those of the scales of the rootstalk, it varies considerably. The most readily recognizable of these variants occur in Mexico and Central America and it is these divergent forms which are considered in the present paper. A key is given to the several species and varieties of this group and synonyms and exsiccatae are freely cited. The following new species and varieties and new combinations are described: *P. lanceolatum* L. var. *complanatum*, *P. lanceolatum* L. var. *crassinervatum* (*Drynaria crassinervatum* Fée), *P. lanceolatum* L. var. *tricophorum*, *P. erythrolepis*, *P. Conzattii*, *P. fruticosum* Maxon & Weatherby, *P. panamense*.—E. B. Payson.

SPERMATOPHYTES

2178. AMES, O. Descriptions of new orchids from tropical America with nomenclatorial changes. Proc. Biol. Soc. Washington 35: 81-88. 1922.—*Aa Rosei*, *Bletia Nelsonii*, *Malaxis mexicana*, *M. Rosei*, *M. tepicana*, *Pelexia Mazonii*, *Platystele compacta*, *Pleurothallis palliolata*, and *Stelis Johnsonii* are described as new species. The following new combinations are made: *Malaxis acianthoides* (*Microstylis acianthoides* Schltr.), *Malaxis blephariglottis* (*Microstylis blephariglottis* Schltr.), *Malaxis brachyrrhyncha* (*Microstylis brachyrrhyncha* Reichb. f.), *Malaxis Javesiae* (*Microstylis Javesiae* Reichb. f.), *Malaxis lepanthiflora* (*Microstylis lepanthiflora* Schltr.), *Malaxis lepidota* (*Microstylis lepidota* Finet), *Malaxis linguella* (*Microstylis linguella* Reichb. f.), *Malaxis minutiflora* (*Microstylis minutiflora* Schltr.), *Malaxis monticola* (*Microstylis monticola* Schltr.), *Malaxis ocreata* (*Microstylis ocreata* S. Wats.), *Malaxis pandurata* (*Microstylis pandurata* Schltr.), *Malaxis Pittieri* (*Microstylis Pittieri* Schltr.), *Malaxis platyglossa* (*Microstylis platyglossa* Robins. & Greenm.), *Malaxis Pringlei* (*Microstylis Pringlei* S. Wats.), *Malaxis streptopetala* (*Microstylis streptopetala* Robins. & Greenm.), *Malaxis tenuis* (*Microstylis tenuis* S. Wats.), *Malaxis Tonduzii* (*Microstylis Tonduzii* Schltr.), *Malaxis Tuerckheimii* (*Microstylis Tuerckheimii* Schltr.), *Malaxis Wercklei* (*Microstylis Wercklei* Schltr.).—J. C. Gilman.

2179. ASHE, W. W. Notes on trees and shrubs of southeastern North America. Rhodora 24: 77-79. 1922.—The range of *Viburnum densiflorum* Chapm. is extended from Alabama into Newton County, Texas, and of *Quercus hybrida* (Chapm.) Small from Mississippi into Newton County; *Quercus obtusa* (Willd.) Ashe is maintained as a coastal plain species distinct from *Q. laurifolia* Michx. The following are new: *Quercus arenicola* n. nom., based on *Q. hybrida* (Chapm.) Small (1903), not Bechst. (1829); *Q. arenicola integra* n. var.; *Q. obtusa obovatifolia* (Sargent) n. comb., based on *Q. rhombica* var. *obovatifolia* Sargent; *Q. moultonensis* n. nom., based on *Q. hybrida* Houba (1887), not Bechst. (1829); *Q. nigra heterophylla* n. comb., based on *Q. aquatica* var. Ait., and *Acer barbatum sinuosum* (Rehder) n. comb., based on *A. sinuosum* Rehder.—M. L. Fernald.

2180. ASHE, W. W. Notes on the trees and shrubs of the southeastern United States. Bull. Torrey Bot. Club 49: 265-268. 1922.—The following are published: *Castanea pumila* Margaretta var. nov., *C. floridana* (Sarg.) comb. nov., *C. Ashei* (Sudworth) comb. nov., \times *Quercus coloradensis* hybr. nov. (*Q. virginiana* Mill. \times *Q. macrocarpa* Michx.), *Q. nigra elongata* comb. nov., *Malus elongata pubens* var. nov., and *M. platycarpa parvula* var. nov. A key is given to the *Castanea pumila* group.—P. A. Munz.

2181. BARTLETT, H. H. Color types of *Corallorrhiza maculata* Raf. Rhodora 24: 145-148. 1922.—Three color types from Michigan are described and designated *Corallorrhiza maculata* var. *flavida* (Peck) n. comb., based on *C. multiflora flavida* Peck, var. *fusca* n. var., and var. *punicea* n. var.—M. L. Fernald.

2182. BLAKE, S. F. **New Asteraceae from Utah and Nevada.** Proc. Biol. Soc. Washington 35: 173-178. 1922.—*Chrysopsis viscida cinerascens*, *Aster glaucodes pulcher*, *Erigeron caespitosus anactis*, and *Tetradymia comosa tetrameres* are described as new subspecies. *Aplopappus brickellioides*, *Aster bellus*, *Bahia ourolepis*, and *Ptiloria cinerea* are described as new species.—J. C. Gilman.

2183. BLAKE, S. F. **New plants from South and Central America collected by Wilson Popenoe.** Proc. Biol. Soc. Washington 35: 117-124. 1922.—*Tibouchina asperipilis*, *Centronia tunguraguae*, *Gaultheria pubiflora*, *Disterigma margaricoccum*, *D. Popenoei*, *Macleania irazuensis*, *M. laurina*, *M. Popenoei*, and *Citharexylum subflavescens* are described as new species.—J. C. Gilman.

2184. BLAKE, S. F. **The identity of the genus *Adventina* Raf.** *Rhodora* 24: 34-36. 1922.—Rafinesque's *Adventina* (1836) proves to be identical with *Galinsoga* Cav. (1794) and his *Adventina ciliata* forms the basis of *Galinsoga ciliata* (Raf.) n. comb., which is identical with *G. aristulata* Bicknell (1916). Rafinesque's account furnished the first records of either *G. aristulata* or *G. parviflora* in the U. S. A.—M. L. Fernald.

2185. BLAKE, S. F. **Two new species of Moraceae from South America.** Proc. Biol. Soc. Washington 35: 179-180. 1922.—The species described are *Brosimum columbianum* and *Brosimopsis diandra*.—J. C. Gilman.

2186. BRITTON, N. L., and J. N. ROSE. **Two new genera of Cactaceae.** Bull. Torrey Bot. Club 49: 251-252. 1922.—*Thelocactus* (Schumann), formerly a subgenus under *Echinocactus*, is raised to generic rank; *Neolloydia* gen. nov. is published. The following new combinations are made: *Thelocactus hexaedrophorus* (Lemaire), *T. bicolor* (Galeotti), *T. lophothele* (Salm-Dyck), *Neolloydia conoidea* (De Candolle), and *N. Beguinii* (Weber). The first named species under each genus is the type species.—P. A. Munz.

2187. ENGLER, A. **Additamentum ad Araceas-Philodendroideas.** Das Pflanzenreich Heft 71 (IV. 23E). 2* p. 1920.—This is a short supplement to Engler and Kraus *Araceae-Philodendroideae-Philodendreae*, Das Pflanzenreich Heft 55 (IV. 23Da), 1912, and concerns primarily the genera *Ariarum* and *Piptospatha*. One new combination is included, namely, *Piptospatha perakensis* (*P. elongata* N. E. Brown var. *perakensis* Engler, *Rhynchophyle perakensis* Ridley).—J. M. Greenman.

2188. ENGLER, A., und K. KRAUSE. **Araceae-Colocasioideae.** Das Pflanzenreich Heft 71 (IV. 23E). 139 p., 29 fig. 1920.—Three tribes are included in the subfamily treated in the present part, namely, *Colocasieae*, *Syngonieae*, and *Ariopsidae*. These tribes embrace 15 tropical genera of which the largest and best known are *Alocasia*, *Xanthosma*, *Caladium*, and *Syngonium*. The following new species, varieties, and combinations are included; and the authorship, unless otherwise indicated, should be attributed to Engler: *Steudnera Henryana*; *S. Gagei* Krause; *Gonatanthus punilius* Engl. & Krause (*Caladium punilum* D. Don); *Caladium angustifolium*; *C. Schomburgkii* Schott var. *venosum* (*C. venosum* N. E. Brown) and *rubescens* (*C. rubescens* N. E. Brown); *C. bicolor* (Ait.) Vent. vars. *surinamense* (*C. surinamense* Miq.), *bohemicum* (*C. bohemicum* Hort.), and *roseo-maculatum*; *C. picturatum* C. Koch vars. *adamanthinum* (*C. adamantinum* L. Lind.) and *sagittatum* (*C. sagittatum* L. Lind. & Rodig.); *Xanthosma atrovirens* C. Koch vars. *Kochii*, *Moritzii* (*X. atrovirens* C. Koch & Bouché var. *versicolor* C. Koch), and *panduriforme*; *X. Ulei*; *X. mafaffa* Schott var. *typicum*; *X. belophyllum* (Willd.) Kunth var. *Kunthii*; *X. obtusilobum*; *X. Buchtienii*; *X. Riedelianum* Schott var. *brancoanum*; *X. Eggersii* (*Caladium Eggersii* Engl.); *X. brasiliense* (*Caladium brasiliense* Desf); *X. helleborifolium* (Jacq.) Schott vars. *angustisectum* (*X. angustisectum* Engl.) and *Weberbaueri*; *Colocasia antiquorum* Schott var. *globulifera* Engl. & Krause; *Alocasia Merrillii* Engl. & Krause; *A. atropurpurea*; *A. Gageana* Engl. & Krause; *A. crassinervia*; *A. crassifolia*; *A. inornata* Hallier f.; *A. indica* (Roxb.) Schott vars. *typica*, *violacea*, and *diversifolia* (*A. indica* var. *hetero-*

phylla (Schott) Engl.); *A. Lecomtei*; *A. tonkinensis*; *A. hainanensis* Krause; *A. grata* Prain; *A. denudata* Engl. var. *elongato*; *A. Uhinkii* Hort. (*A. macrorrhiza* × *indica* var. *metallica*); *A. Leopoldi* Hort. (? *A. indica* × *Sanderiana*); *A. splendens* (Hort.) Linden (? *A. indica* × *Sanderiana*); *A. subodora* Engl. & Krause (*A. odora* × *argyrea*); *Schizocasia acuta* Engl. var. *typica*; *Syngonium Rothschuhianum*; *S. Vellozianum* Schott var. *oblongisectum*; *S. macrophyllum*; *S. amazonicum*; *S. podophyllum* Schott vars. *Oerstedianum* (*S. Oerstedianum* Schott), *multi-sectum*, and *albolineatum* (*S. albolineatum* Hort.).—J. M. Greenman.

2189. FASSETT, NORMAN C. *Lophotocarpus* on the northeastern river-estuaries. *Rhodora* 24: 71-73. Pl. 137. 1922.—*Lophotocarpus calycinus* (Engelm.) J. G. Smith, a southern species, has well developed sagittate leafblades; while the more northern *L. spongiosus* (Engelm.) J. G. Smith, a plant confined to estuaries from the Delaware River to the Gulf of St. Lawrence, has the blades commonly obsolete. No differences are found in the fruit and study of a large series of specimens demonstrates that where their ranges are coincident the 2 plants intergrade but northward the sagittate blades become progressively rarer until the more northern colonies bear only phyllodia. The new combination, *L. calycinus* var. *spongiosus* (Engelm.) Fassett, is made—M. L. Fernald.

2190. FERNALD, M. L. *Brassica arvensis* (L.) Kuntze, var. *Schkuhriana* (Reichenb.) n. comb. *Rhodora* 24: 36. 1922.—The transfer is based on *Sinapis Schkuhriana* Reichenb. (1837-38).—M. L. Fernald.

2191. FERNALD, M. L. *Lysimachia terrestris* (L.) BSP., var. *ovata* (Rand and Redfield), n. comb. *Rhodora* 24: 76. 1922.—The new combination is based on *L. stricta* var. *ovata* Rand & Redfield (1894).—M. L. Fernald.

2192. FERNALD, M. L. Notes on *Sparganium*. *Rhodora* 24: 26-34. 1922.—Notes are given on the identity and geographic distribution of critical American species, with key to the species of eastern North America. The following are recognized: *S. eurycarpum* Engelm., *S. androcladum* (Engelm.) Morong (*S. lucidum* Fernald & Eames), *S. americanum* Nutt., *S. chlorocarpum* Rydberg (*S. diversifolium* of American authors), *S. chlorocarpum* var. *acaule* (Beeby) n. comb., *S. angustifolium* Michx. (*S. affine* Schnitzl.), *S. fluctuans* (Morong) Robinson, *S. minimum* Fries, and *S. hyperboreum* Laestad.—M. L. Fernald.

2193. FERNALD, M. L. Some variations of *Cakile edentula*. *Rhodora* 24: 21-23. 1922.—The author divides the species into var. *typica* (Iceland and Labrador to South Carolina; Azores), var. *lacustris* n. var. (strands of the Great Lakes), and var. *californica* (Heller) n. comb. (*C. californica* Heller, British Columbia to California).—M. L. Fernald.

2194. FERNALD, M. L. The American variations of *Linnaea borealis*. *Rhodora* 24: 210-212. 1922.—The author recognizes in America: typical *L. borealis* L. (*L. serpyllifolia* Rydb.) in Alaska; var. *americana* (Forbes) Rehder, Greenland and Labrador to Alaska and south to the northern and upland states; var. *longiflora* Torr., British Columbia to northern California.—M. L. Fernald.

2195. FERNALD, M. L. The generic name *Phragmites*. *Rhodora* 24: 55-56. 1922.—The author discusses the names *Phragmites* and *Trichoon* Roth (1798), the latter taken up by some European authors as antedating *Phragmites* Trin. (1820). The latter name, however, dates from Adanson (1763) and should be retained.—M. L. Fernald.

2196. FERNALD, M. L., and C. A. WEATHERBY. Varieties of *Geum canadense*. *Rhodora* 24: 47-50. 1922.—Besides typical *G. canadense* the following are recognized: forma *glandulosum* n. f., var. *texanum* n. var., var. *camporum* (Rydberg) n. comb. (*G. camporum* Rydberg), var. *camporum* f. *adenophorum* n. f., var. *Grimesii* n. var.—M. L. Fernald.

2197. GLEASON, HENRY ALLEN. *Vernonieae*. North Amer. Flora 33: 47-110. 1922.—As the first tribe of the *Carduaceae* the author presents a complete treatment of the 19 recognized genera of this tribe. Of these 19 genera *Vernonia* is the largest with 123 species. Keys to the genera and species are given as well as a complete citation of synonymy, statement of type localities, distribution, and illustrations. The following new species and new combinations are included: *Centratherum violaceum* (*Spixia violacea* Schrank), *Vernonia callilepis*, *Eremosia oolepis* (*Vernonia oolepis* Blake), *E. angusta*, *E. callilepis* (*Vernonia Steetzii* var. *callilepis* Schz. Bip.), *E. obtusa*, *E. littoralis* (*Vernonia littoralis* Brand.), *Oliganthes ferruginea*.—*E. B. Payson*.

2198. HOEHNE, F. C. *Melastomáceas dos Hervários: Horto "Oswaldo Cruz," Museu Paulista, Comissão de Linhas Telegráficas Estratégicas de Mato-Grosso ao Amazonas, Jardim Botânico do Rio de Janeiro, etc.* [Melastomaceae of the herbaria of the Horto "Oswaldo Cruz," Paulista Museum, Commission of the strategic telegraph lines of Mato-Grosso on the Amazon, of the Botanical Garden of Rio de Janeiro, etc.] *Anexos Mem. Inst. Butantan [Bot.] 15: 1-198. Pl. 1-21, and frontispiece.* 1922.—The Melastomaceae represented in the various herbaria mentioned are treated in detail with brief descriptions, critical notes, and the citation of specimens for each species. The following species and varieties are described as new: *Microlicia Warmingiana* Cgn. var. *glandulosa*, *M. insignioides*, *M. insignioides* var. *gracilis*, *M. suborbicularifolia*, *M. sulfurea*, *M. Bradeana*, *Lavoisiera itabirana*, *Rhynchanthera spicata*, *R. corumbaensis*, *R. cacerensis*, *R. linearifolia*, *R. coxinnensis*, *Poteranthera genliseoides*, *Acisanthera bracteosa* (*Comolia bracteosa* Huber), *Macairea villosa*, *M. goyazensis*, *Tibouchina paulistana*, *T. Valtherii* Cgn. var. *minor*, *T. urceolaris* Cgn. var. *papillosa*, *T. rupicola*, *Comolia affinis*, *C. Kuhlmannii*, *Leandra purpureo-villosa*, *L. xantholasia* Cgn. var. *setulosa*, *L. cardiophylla* Cgn. var. *integra*, *L. aurea* Cgn. var. *aggregatiflora*, *L. sparsisetulosa*, *L. hirtella* Cgn. var. *Löfgrenii*, *L. pauloensis*, *Miconia nambyquarae*, *M. Camposnovaesii*, *M. rubiginosa* DC. var. *Kuhlmannii*, *M. cubatanensis*, *M. petropolitana* Cgn. var. *macrophylla*, *M. mattogrossensis*, *M. theaezans* Cgn. var. *setulosa*, *Tococa Kuhlmannii*, *Clidemia cubatanensis*, *C. Kuhlmannii*, *C. longisetosa*, *C. rubra* Mart. var. *ursina*, *C. pusilliflora*, *Henriettella Duckeana*, *Ossaea Duckeana*, *Topobea rupicola*, *Mouriria pusa* Gardn. var. *grandifolia*.—*E. B. Payson*.

2199. INMAN, O. L. *Calamagrostis canadensis* and some related species. *Rhodora 24: 142-144.* 1922.—The author gives a key to and synonymy of *Calamagrostis Macouniana* Vasey, *C. canadensis* (Michx.) Nutt., *C. canadensis* var. *robusta* Vasey, *C. canadensis* var. *Langsdorfi* (Link) n. comb. based on *Arundo Langsdorfi* Link, *C. blanda* Beal, *C. perplexa* Scribn., *C. Porteri* Gray, and *C. Scribneri* Beal.—*M. L. Fernald*.

2200. KRAUSE, K., e F. C. HOEHNE. *Contribuições ao conhecimento das Rubiaceas do Brasil meridional.* [Contributions to the knowledge of the Rubiaceae of southern Brazil.] *Anexos Mem. Inst. Butantan [Bot.] 15: 1-33. Pl. 1-6.* 1922.—Many Rubiaceae species of southern Brazil are listed with notes as to their distribution, habits of growth, and common names. The following species are described as new by K. Krause: *Coccocypselum cordatum*, *Psychotria florestana*, *P. Hoehnei*, *Palicourea Hoehnei*, *Faramea Hoehnei*, *Richarsonia acutifolia*.—*E. B. Payson*.

2201. LINDER, D. H. Some varieties of *Panicum virgatum*. *Rhodora 24: 11-16. Fig. 1-6.* 1922.—The following varieties are discussed: var. *cubense* Griseb., var. *scorteum* n. var. from Bermuda, var. *thyrsiforme* n. var. from Florida and Mississippi; var. *spissum* n. var. from Nova Scotia to New Jersey and central New York.—*M. L. Fernald*.

2202. LINGELSHEIM, A. *Oleaceae-Oleoideae-Fraxineae und Oleaceae-Oleoideae-Syringaeae.* *Das Pflanzenreich Heft 72 (IV. 243 i u. ii).* 125 p., 22 fig., 1 map. 1920.—Two genera are included in the tribe *Fraxineae*, namely, *Fontanesia* and *Fraxinus*. The former has but a single species, *Fontanesia phillyreoides* Labill., with varieties *mediterranea* (F. *phillyreoides* C. K. Schneider) of the Mediterranean region and *Fortunei* (Carr.) Koehne of

China. *Fraxinus* includes 64 recognized species and numerous varieties. The following new species, varieties, and combinations are recorded: *Fraxinus ornus* L. vars. *typica* Lingelsh. and *sanguinea* Hausmann & Lingelsh., *F. Paxiana* Lingelsh. var. *depauperata*, *F. retusa* Champ. vars. *typica* and *integra*, *F. fallax*, *F. stylosa*, *F. longicuspis* Sieb. & Zucc. var. *Sieboldiana* (Blume), *F. chinensis* Roxb. vars. *typica*, *rotundata*, *tomentosa*, and *acummata*, *F. yunnanensis* (*F. velutina* Lingelsh., not Torr.), *F. dipetala* Hook. & Arn. var. *typica*, *F. Schiedeana* Schlecht. & Cham. vars. *typica* and *palmarum*, *F. Jonesii*, *F. xanthoxyloides* Wall. var. *dimorpha* (Coss. & Dur.), *F. americana* L. var. *albicans* (Buckl.), *F. pennsylvanica* Marsh. var. *pubescens* (Lam.), *F. Rehderiana*, *F. oregona* Nutt. vars. *latifolia* (Benth.) and *glabra*, *F. velutina* Torr. vars. *typica*, *glabrata*, and *coriacea* (Wats.), *F. lanceolata* Borkh. vars. *viridis* (Michx.), *macrocarpa*, and *Lindheimeri* (Wenzig), *F. Uhdei* (Wenzig) Lingelsh. vars. *typica* and *pseudoperiptera*, *F. caroliniana* Mill. vars. *platycarpa* (Michx.) and *cubensis* (Griseb.), *F. elbursensis*, *F. syriaca* Boiss. var. *persica* (Boiss.), *F. oxycarpa* Willd. vars. *oxyphylla* (Marsch. Bieb.), *angustifolia* (Vahl), *algeriensis*, *australis* (Gay), *macrocarpa*, and *tamariscifolia* (Vahl), *F. Bornmülleri*, *F. Brandisii*, and *F. nigra* Marsh. vars. *sambucifolia* (Lam.) and *mandschurica* (Rupr.). Two new hybrids are also recorded, namely, *F. americana* × *pennsylvanica* (*F. Biltmoreana* Beadle) and *F. lanceolata* × *pennsylvanica* (*F. cinerea* Bosc.). A map accompanies the text, which shows the geographical distribution of *Fraxinus*. The tribe *Syringaceae* embraces 3 genera, namely, *Syringa*, *Schrebera*, and *Forsythia*. These genera, on account of the long corolla-tube, dehiscence of capsule, and winged seeds, constitute a natural group; their center of geographical distribution is in central Asia. The following new species, varieties, and combinations are recorded: *Syringa villosa* Vahl var. *Limprichtii*, *S. glabra* (*S. villosa* var. *glabra* C. K. Schneider), *S. Schneideri* (*S. Dielsiana* Schneider, in part), *S. oblata* Lindl. vars. *typica* and *affinis* (*S. affinis* Henry), *S. persica* L. vars. *typica* and *coriacea*, *S. amurensis* Rupr. var. *rotundifolia* (Decne.), *Schrebera Schellenbergii*, *S. excelsa* with vars. *typica* and *somnifera*, *S. Nyassae*, *S. Gilgiana*, and *Forsythia suspensa* (Thunb.) Vahl var. *pubescens* (Rehder).—J. M. Greenman.

2203. MACBRIDE, J. FRANCIS. A revision of *Astragalus*, subgenus *Homalobus*, in the Rocky Mountains. Contrib. Gray Herb. 65: 28–39. 1922.—The author treats the species of this group from the same range as is included in Rydberg's *Flora of the Rocky Mountains and Adjacent Plains*, but recognizes only 26 species instead of the 45 maintained by Rydberg under *Homalobus* as a distinct genus. A dichotomous key is presented for the species and varieties treated. Specimens are cited for each species and variety and synonyms are freely included. The following new names, varieties, and forms occur: *Astragalus tenellus* Pursh forma *strigulosus* (*Homalobus strigulosus* Rydb.), *A. tenellus* Pursh var. *Clementis* (*Homalobus Clementis* Rydb.), *A. tenellus* Pursh forma *acerbus* (*A. acerbus* Sheld.), *A. campestris* (Nutt.) Gray var. *diversifolius* (*A. diversifolius* Gray), *A. Garrettii* (*Homalobus paucijugus* Rydb.), *A. Carletonii* (*Homalobus humilis* Rydb.), *A. hylophilus* (Rydb.) A. Nels. var. *oblongifolius* (*Homalobus oblongifolius* Rydb.), *A. Rydbergii* (*Homalobus decurrens* Rydb.) *A. serotinus* Gray var. *strigosus* (*A. strigosus* Coult. & Fish.), *A. serotinus* Gray var. *Palliseri* (*A. Palliseri* Gray), *A. curvicarpus* (*A. speiroparpus* Gray var. *curvicarpus* Sheld.).—E. B. Payson.

2204. MACBRIDE, J. FRANCIS. Notes on certain Leguminosae of the tribe Psoraleae. Contrib. Gray Herb. 65: 14–23. 1922.—The following new species and varieties as well as new names and combinations are given: *Psoralea tenuiflora* Pursh var. *Bigelovii* (*Psoralidium Bigelovii* Rydb.), *P. scaposa* (*P. hypogaea* Nutt. var. *scaposa* Gray), *P. humilis* (*Pedimelum humile* Rydb.), *P. macrostachya* DC. var. *longiloba* (*Hoita longiloba* Rydb.), *P. arosela* Benth. (*Dalea Benth. Brandg.*), *P. megacarpa* (*Dalea megacarpa* Wats.), *P. Fremontii* (Torr.) Vail var. *Wheeleri* Robinson (*P. Wheeleri* Vail), *P. Fremontii* (Torr.) Vail var. *Saundersii* (*Dalea Saundersii* Pursh), *P. tinctoria* (*Dalea tinctoria* Brandg.), *P. mollis* (Benth.), Heller var. *neo-mexicana* (*Dalea mollis* Benth. var. ? *neo-mexicana* Gray), *P. laxiflora* (*Dalea laxiflora* Schlecht.), *P. leporina* (Ait.) Rydb. var. *alba* (*Dalea alba* Michx.), *P. leporina* (Ait.) Rydb. var. *Thouini* (*Dalea Thouini* Schrank), *P. vernicia* Rose var. *citrina* (*P. citrina* Rydb.), *P. tomentosa* (Cav.) Rose var. *psoraleoides* (*Dalea psoraleoides* Moric.), *P. polycephala* (Benth.)

Rydb. var. *minutifolia* (*P. minutifolia* Rydb.), *P. triphylla* (*Dalea triphylla* Sessé & Moc.), *P. versicolor* (Zucc.) Rydb. var. *tsugoides* (*P. tsugoides* Rydb.), *P. Wislizeni* (Gray) Vail var. *Sanctae-Crucis* (*P. Sanctae-Crucis* Rydb.), *P. lasiostachya* (Benth.) Rose var. *glabrescens* (*P. glabrescens* Rydb.), *P. lasiostachya* (Benth.) Rose var. *involuta* (*P. involuta* Rydb.), *P. lutea* Cav. var. *caudata* (*P. caudata* Rydb.), *P. Arsenei*, *P. Dalea* (L.) Britton var. *robusta* (*Thornbera robusta* Rydb.), *P. pumila* (*Thornbera pumila* Rydb.), *P. tenuicaulis* (*Dalea tenuicaulis* Hook. f.), *P. pazensis* (*Dalea pazensis* Rusby), *P. parvifolia* (*Dalea parvifolia* Hook. f.), *P. multifoliolata* (*Psoralea multifoliolata* Clos), *P. humifusa* (*Dalea humifusa* Benth.), *P. cylindrica* (*Dalea cylindrica* Hook.), *P. coerulea* (*Galega coerulea* L. f.), *P. calliantha* (*Dalea calliantha* Ulbrich), and *P. boliviana* (*Dalea boliviana* Britton). A key is given to the species closely related to *Parosela microphylla*.—E. B. Payson.

2205. MACBRIDE, J. FRANCIS. Various North American spermatophytes, new or transferred. Contrib. Gray Herb. 65: 39-46. 1922.—The following new species, varieties, new combinations, and new names are given: *Cleome lutea* Hook. var. *Jonesii*, *Lotus Torreii* (Gray) Greene var. *seorsus*, *Mentzelia laevicaulis* (Dougl.) T. & G. var. *acuminata* Nels. & Macbride (*Nuttallia acuminata* Rydb.), *M. parviflora* (*Bartonia parviflora* Dougl.), *Opuntia compressa* (*Cactus compressus* Salisb.), *Oenothera Abramsi*, *O. erythra* (*Sphaerostigma erythra* Davidson), *Gomphocarpus Torreii*, *G. Torreii* var. *Xanti* (*G. tomentosus* (Torr.) Gray var. *Xanti* Gray), *Phacelia viscida* (Benth.) Torr. forma *albiflora* (*Eutoca albiflora* Nutt.), *Allocarya stipitata* Greene var. *micrantha* (*A. stipitata* Greene subsp. *micrantha* Piper), *Solanum Xanti* Gray var. *Spenceriae*, *Castilleja Douglasii* Benth. var. *contentiosa*, *Lepachys columnifera* (*Rudbeckia columnifera* Nutt.), *Stephanomeria Wheeleri* (*Chaetadelphia Wheeleri* Gray).—E. B. Payson.

2206. MAIDEN, J. H. A critical revision of the genus *Eucalyptus*. Vol. VI, Part 4. pp. 165-218, pl. 220-223. John Spence: Sydney, July 1922.—In this number the author continues his discussion of hybrids, and adds a 3rd chapter on timber. Two hybrids between *Eucalyptus sideroxylon* A. Cunn. and *E. leucoxylon* F. v. M. are recorded. A 3rd new hybrid \times *E. mcintyrensis* from Mount McIntyre, South Australia, is characterized. Under the caption "Fossil plants attributed to *Eucalyptus*" a brief résumé of the subject is given and the following fossil plants, found in Australia and Tasmania, although previously published, are here redescribed and illustrated: *Eucalyptus Plutii* McCoy; *E. Kayseri* and *E. Milligani* Johnston; *E. Delftii*, *E. Diemenii*, *E. Hayi*, *E. Houtmanni*, *E. Mitchelli*, *E. cretacea*, *E. Davidsoni*, *E. oxleyana*, *E. scoliophylla*, and *E. Warraghiana* Ettingshausen; *E. praecoriacea*, *E. Hermani*, *E. Howittii*, *E. Kitsoni*, *E. Suttoni* (*E. Muelleri* Deane), and *E. Chapmani* Deane (*E. Woollsii* Deane).—J. M. Greenman.

2207. MERRILL, E. D. New or noteworthy Philippine plants, XVII. Philippine Jour. Sci. 20: 367-476. 1922.—One hundred six new species are described, while certain changes in nomenclature are proposed, the most important of which is the acceptance of *Polychroa* Lour. (1790) in place of *Pellionia* Gaudich. (1826). The proposed new species are as follows: *Ficus Xavieri*, *F. kalingaensis*, *Elatostema bontocense*, *E. capizense*, *E. Edañoi*, *E. euphlebiu*, *E. kalingaense*, *E. lignosum*, *E. samarense*, *Pipturus angustifolius*, *Polychroa multinervia*, *P. ferruginea*, *Pycnarrhena membranifolia*, *Goniotalamus puncticulifolius*, *Cryptocarya Edañoi*, *C. cagayanensis*, *Rubus perfulvus*, *R. heterosepalus*, *Cassia mindanaensis*, *Mucuna foveolata*, *M. samarensis*, *Evodia confusa*, *Aglaia cupreo-lepidota*, *Dichapetalum euphlebiu*, *Croton lancilimbus*, *Trigonostemon angustifolius*, *Cyclostemon Bavanii*, *C. oligophlebiu*, *Homalanthus concolor*, *Alchornea pubescens*, *Cleistanthus Barrooi*, *Mangifera parvifolia*, *Lophopetalum paucinervium*, *Meliosma bontocensis*, *Guioa mindorensis*, *Rhamnus mollis*, *Leca nitida*, *Saurauia longipedicellata*, *Pyrenaria mindanaensis*, *Calophyllum obliquinervium*, *Casuarina mindanaensis*, *Aquilaria apiculata*, *Eugenia mirabilis*, *E. lancilimba*, *Schefflera bukidnonensis*, *S. halconensis*, *S. cinnamomea*, *Arthropphyllum Cenabrei*, *Alangium pilosum*, *Dimorphanthera mindanaensis*, *Styphelia philippinensis*, *Maesa megalobotrya*, *M. undulata*, *Ardisia calaritensis*, *Discocalyx brachybotrys*, *D. phanerophlebia*, *Embelia elliptica*, *E. luzoniensis*, *E. ovatifolia*, *Rapanea angustifolia*, *R. oblongibacca*, *Madhuca philippinensis*, *Linociera longifolia*, *Gentostoma acumi-*

natissima, *Strychnos Cenabrei*, *Tabernaemontana mindorensis*, *Kopsia grandiflora*, *Clerodendron luzoniense*, *Callicarpa magnifolia*, *Vitex unifoliolata*, *Limnophila obovata*, *Dichrotrichum coriaceum*, *Trichosporum mindanaense*, *Cyrtandra rufotricha*, *C. aclada*, *C. Barnesii*, *C. zamboangensis*, *C. parva*, *C. subglabra*, *Hypoestes mindorensis*, *H. axillaris*, *H. tenuis*, *H. confertiflora*, *Hemigraphis lanceolata*, *H. pachyphylla*, *Peristrophe cordatibractea*, *Strobilanthes pachys* C. B. Clarke, *Hallieracantha brevipetiolata*, *Tarenna pangasinensis*, *Cowiea philippinensis*, *Izora myriantha*, *Pleiocarpidia lanaensis*, *Gardenia megalocarpa*, *Urophyllum mindorensis*, *Argostemma arachnosum*, *Lasianthus mindanaensis*, *L. acuminatissimus*, *Hedyotis camarinensis*, *H. bambusetorum*, *Ophiorrhiza dolichophylla*, *Alsomitra simplicifolia*, *Lonicera mindanaensis*, *Pentaphragma mindanaense*, *Vernonia bontocensis*, *V. mindanaensis*, and *Lactuca integra*. The following new combinations also appear: *Ichnanthus vicinus* (F. M. Bail.), *Cleidion Ramosii* (Merr.), *Hallieracantha aequifolia* (C. B. Clarke), and *H. addisomensis* (Elm.), with *H. Elmeri* as a new name for *Hypoestes pulgarensis* Elm. *Ficus argentea* Blanco, a species of previous entirely doubtful status, is redescribed. Eighteen species of Myrsinaceae recently proposed by Mez are reduced to previously described forms.—E. D. Merrill.

2208. MERRILL, ELMER D. *Studies on Philippine Rubiaceae, IV.* Philippine Jour. Sci. 17: 425-485. 1920.—In this 4th paper of the series, 62 new species are proposed, making 160 new species described in the whole series. The new species are as follows: *Gynochthodes mindanaensis*, *Hedyotis atropurpurea*, *H. brachyantha*, *H. catanduanensis*, *H. diffusissima*, *H. laxiflora*, *H. longipendunculata*, *H. oligantha*, *H. scaberrima*, *H. simplex*, *Izora luzoniensis*, *Morinda coriacea*, *M. nitida*, *Mussaenda acuminatissima*, *Ophiorrhiza Macgregorii*, *O. ovata*, *O. pubiflora*, *O. stenophylla*, *O. tenuis*, *Plectronia brunnea*, *P. oligophlebia*, *P. Ramosii*, *P. subcapitata*, *Psychotria amplissima*, *P. capizensis*, *P. castanea*, *P. cardiophylla*, *P. cordatula*, *P. elliptilimba*, *P. fenicis*, *P. heteromera*, *P. lancilimba*, *P. longipetiolata*, *P. lucida*, *P. magnifolia*, *P. nagapatensis*, *P. obscurinervia*, *P. pallidifolia*, *P. panayensis*, *P. Piperi*, *P. pygmaea*, *P. scaberula*, *P. tricarpa*, *Randia rostrata*, *Tarenna acuminata*, *T. catanduanensis*, *T. elongata*, *T. littoralis*, *T. nitida*, *T. obtusifolia*, *T. stenantha*, *Pavetta Elmeri*, *P. multinervia*, *P. Williamsii*, *P. subferruginea*, *Timonius auriculatus*, *Urophyllum caudatum*, *U. affine*, *U. panayense*, *U. quadribacteolatum*, *Williamsia panayensis*, and *W. longistipula*. The status of *Tarenna* is discussed and 31 Philippine and Indo-Malayan species are enumerated, with the following new names: *T. angustifolia* (*Stylocoryna angustifolia* King), *T. adpressa* (*Stylocoryna adpressa* King), *T. Maingayi* (*Webera Maingayi* Hook. f.), *T. costata* (*Stylocoryna costata* Miq.), *T. pumila* (*Webera pumila* Hook. f.), and *T. buruensis* (*Stylocoryna buruensis* Bartl.).—E. D. Merrill.

2209. OSTERHOUT, GEO. E. *Two new plants from western Colorado.* Bull. Torrey Bot. Club 49: 183-184. 1922.—*Nuttallia marginata* and *Acrolasia humilis* are described as new species.—P. A. Munz.

2210. RADLKOFER, L. *Sapindaceae novae Philippinenses.* Philippine Jour. Sci. 20: 657-662. 1922.—The following new species are described: *Lepisanthes acutissima*, *L. macrocarpa*, *Hedyachras* gen. nov., *H. philippinensis*, *Trigonachras falcatocuspidata*, and *Mischocarpus sublaevis*. An amplified description of *Euphorianthus obtusatus* Radlk., Mindanao-Celebes, is given.—E. D. Merrill.

2211. RENDLE, A. B., E. G. Baker, and S. LE M. MOORE. *A systematic account of the plants collected in New Caledonia and the Isle of Pines by Prof. R. H. Compton, M. A., in 1914.* Part 1. Flowering plants (angiosperms). Jour. Linn. Soc. Bot. London 45: 245-418. Pl. 13-24. 1921.—The paper enumerates 830 species, 230 of which are new, and there are 10 new genera. There are many peculiar endemic forms, and many species are recorded from the island for the 1st time. Much information is presented concerning the distribution of the flora of the region. The families represented by the largest number of species are the Orchidaceae, Euphorbiaceae, Rubiaceae, and Myrtaceae; the families Leguminosae, Saxifragaceae, and Apocynaceae are well represented. The new genera are *Comptonella* (Rutaceae),

Salaciopsis (Celastrineae), **Montagueia** (Anacardiaceae) (commemorating the late Mr. P. D. Montague, zoologist to the expedition), **Paracryphia** (Eucryphiaceae), **Enochoria** (Araliaceae), **Merismostigma** (Rubiaceae), **Tropalanthus** (Sapotaceae), **Depanthus** (Gesneraceae), **Adenodaphne** (Lauraceae), and **Dendrophyllanthus** (Euphorbiaceae). The new species are as follows: **MONOCOTYLEDONS** (by A. B. Rendle, who is each case is authority for the species). *Dendrobium Comptonii*, *Bulbophyllum lingulatum*, *B. Comptonii*, *Phreatia Comptonii*, *Phajus neocaledonicus*, *Calanthe oreadam*, *C. neocaledonica*, *Sarcochilus neocaledonicus*, *Acianthus nanus*, *A. culiciferus*, *A. bracteatus*, *A. corniculatus*, *Campynema neocaledonicum*, *Freycinetia Comptonii*, *F. monticola*, *Eriocaulon Comptonii*, *Costularia neocaledonica*, *Scleria neocaledonica*.—**DICOTYLEDONS**, **Polypetalae** (by E. G. Baker, who in each case is authority for the species): *Hibbertia Comptonii*, *H. dissitiflora*, *H. insulana*, *Drimys Comptonii*, *D. odorata*, *D. pauciflora*, *Ionidium serratum*, *Agation rufo-tomentosum*, *A. longipedicellatum*, *A. Comptonii*, *Pittosporum penduliflorum*, *Garcinia Comptonii*, *Microsema Comptonii*, *Sterculia Comptonii*, *Elaeocarpus nodosus*, *E. toninensis*, *E. dolichopodus*, *E. Comptonii*, *Ryssopteris taomensis*, *Boronella parvifolia*, *Melicope platystemon*, *M. montana*, *Comptonella albiflora*, *Evodia canalisensis*, *E. lactea*, *Zanthoxylon neocaledonicum*, *Z. albiflorum*, *Dutailleya Comptonii*, *Murraya flava*, *Dysoxylum Comptonii*, *D. gamosepalum*, *Sphenostemon Comptonii*, *Salaciopsis neocaledonica*, *Euroschinus rubromarginatus*, *E. sylvicola*, *Montagueia haplostemon*, *Semecarpus ngoyensis*, *Arthroclanthus grandifolius*, *A. Comptonii*, *Phaseolus neocaledonicus*, *Mucuna neocaledonica*, *Storkiella Comptonii*, *Albizia Comptonii*, *Parinarium neocaledonicum*, *P. minutiflorum*, *Geissois magnifica*, *Codia tinifolia*, *Pancheria rubrivenia*, *P. communis*, *Spiraeanthemum Comptonii*, *S. rubescens*, *Polysoma Comptonii*, *Paracryphia suaveolens*, *Terminalia rubricarpa*, *Cloezia Comptonii*, *C. angustifolia*, *Myrtus proliza*, *M. luteoviridis*, *Eugenia gyrosepala*, *E. angustibracteolata*, *E. mouensis*, *E. stephanophylla*, *E. brachycalyx*, *E. hydrophila*, *E. ignambiensis*, *E. arborea*, *E. Comptonii*, *E. neocaledonica*, *E. toninensis*, *E. paniensis*, *Psidium kuakuense*, *Casearia Comptonii*, *Homalium sylvicolum*, *Schefflera combouiensis*, *S. Comptonii*, *Dizygotheca polyantha*, *Eremopanax canalisensis*, *Enochoria sylvicola*, *Apiopetalum arboreum*. **DICOTYLEDONS**, **Gametatae** (by S. Le M. Moore, who in every case is authority for the species): *Bikkia fulgida*, *B. alyxioides*, *B. truncata*, *B. Comptonii*, *Lucinaea neocaledonica*, *Randia Comptonii*, *Gardenia cerifera*, *G. sylvestris*, *Atractocarpus cucumicarpus*, *A. oblongus*, *Cyclophyllum cymosum*, *Merismostigma neocaledonicum*, *Ixora kuakuensis*, *I. florida*, *I. Comptonii*, *Morinda ligustrina*, *Psychotria suaveolens*, *P. Comptonii*, *P. frondosa*, *P. pubituba*, *P. declieuxioides*, *P. laxissima*, *P. subpallens*, *P. rarifolia*, *P. roseo-tincta*, *P. lepidocalyx*, *P. toninensis*, *P. gneissica*, *P. patula*, *Cephaelis saltiensis*, *C. rubefacta*, *C. bowardioides*, *Lagenophora neocaledonica*, *Erigeron neocaledonicus*, *Blumea canalisensis*, *Scaevola rotundata*, *Dracophyllum compactum*, *Rapanea grandifolia*, *Chrysophyllum gordoniaefolium*, *C. floribundum*, *C. Comptonii*, *C. peninsulare*, *Planchonella serpentina*, *P. saligna*, *Palaquium neocaledonicum*, *Tropalanthus Sealyae*, *T. Comptonii*, *Symplocos calophylloides*, *S. munda*, *Melodinus paucivenosus*, *M. citricarpus*, *Rauwolfia suaveolens*, *Alyxia nummularia*, *A. Johnsoniae*, *A. serpentina*, *Pterochrosia Comptonii*, *P. neriifolia*, *Alstonia lanceolifera*, *A. retusa*, *A. Comptonii*, *A. saligna*, *Parsonsia Comptonii*, *P. effusa*, *P. taomensis*, *Tylophora insulicola*, *Marsdenia assimulata*, *Hoya limoniaca*, *Geniostoma lopeziaefolium*, *G. consimile*, *G. sluggeoides*, *G. oleifolium*, *Lindernia neocaledonica*, *Depanthus glaber* (*Coronanthus glabra* C. B. Clarke), *Pseuderanthemum Comptonii*, *Justica pinensis*, *Myoporum rotundatum*, *Gmelina neocaledonica*, *Oxera crassiflora*, *O. Comptonii*, *O. gmelinoides*. **MONOCHLAMYDEAE** (by S. Le M. Moore, who, except where otherwise indicated, is authority for the species): *Timeroa canalisensis*, *Atriplex jubata*, *Nepenthes humilis*, *Piper Comptonii*, *Hedycarya saligna*, *H. Engleriana*, *H. Comptonii*, *H. symplocoides*, *H. Perkinsiana*, *Trimenia neocaledonica* Bak. fil., *Adenodaphne corifolia*, *Litsea neocaledonica*, *Beauprea multijuga*, *B. Comptonii*, *Grevillea acervata*, *G. Comptonii*, *G. producta*, *Stenocarpus Comptonii*, *S. phyllodineus*, *Loranthus pustulatus*, *L. glaucescens*, *L. Comptonii*, *L. canalisensis*, *L. angustiflorus*, *Exocarpus dilatatus*, *Ricinocarpus neocaledonicus*, *Dendrophyllanthus Comptonii*, *Phyllanthus triquetrus*, *P. durus*, *P. rhodocladus*, *P. induratus*, *P. casearioides*, *P. Comptonii*, *P. salacioides*, *P. maytenifolius*, *P. serpentinus*, *P. gneissicus*, *P. toninensis*, *P. pterocladus*, *P. castus*, *P. sylvicola*, *P. ligustrifolius*, *Acalypha finitima*, *Cleidion viridiflorum*, *C. sylvestre*, *C. panduratum*, *C. Comptonii*, *C. obovatum*, *C. paucidentatum*, *Macaranga longispica*, *M. mista*, *M. meiophylla*, *M. porrecta*, *Balanops reticulata*, *B. acicarpa*, *Ficus Comptonii*, *F. leptorhachis*, *F. oreadam*, *F. cretacea*, *F. campicola*.—A. J. Eames.

2212. ROBINSON, B. L. *Dyscritothamnus*, a new genus of Compositae. *Contrib. Gray Herb.* 65: 24-28. Pl. 1. 1922.—*Dyscritothamnus* is described as a genus of Compositae new to science. To it is assigned one species, *D. filifolius*. It is based upon a somewhat fragmentary specimen collected in 1840 by Ehrenberg near the boundary between Queretaro and Hidalgo in Mexico. It seems to be intermediate in relationship between the Eupatorieae and the Astereae but is tentatively referred to the former.—E. B. Payson.

2213. ROBINSON, B. L. Records preliminary to a general treatment of the Eupatorieae II. *Contrib. Gray Herb.* 65: 46-54. 1922.—The following species and varieties are described as new to science: *Eupatorium angulifolium*, *E. angulifolium* vars. *typicum* and *fratri*, *E. elegans* HBK. vars. *typicum* and *pubens*, *E. neriifolium*, *E. militare*, *E. sagittiferum*, and *Kanimia microphylla*. *Eupatorium subpenninervium* Sch. Bip. and *E. viscosum* HBK. are discussed.—E. B. Payson.

2214. ROWLEE, W. W. The genus *Costus* in Central America. *Bull. Torrey Bot. Club* 49: 283-292. Pl. 12-15. 1922.—A key to the Central American species of *Costus* is given with a discussion of the species, of which the following new ones are described: *C. bracteatus*, *C. sepauculensis*, and *C. congestus*.—P. A. Munz.

2215. RUSBY, H. H. New species of trees of medical interest from Bolivia. *Bull. Torrey Bot. Club* 49: 259-264. 1922.—The following new species are published: *Nectandra coto*, *Ocotea pseudo-coto*, *Aerodiclidium benense*, *Guarea Bangii*, and *G. alborosea*. The bark of the 1st one named is the source of "coto," that of the 2nd is sold as such but is worthless; the 4th furnishes spurious "cocillana."—P. A. Munz.

2216. SCHLECHTER, R. Orchidaceae Bradeanae Paulenses. *Anexos Mem. Inst. Butantan [Bot.]* 14: 1-68. Pl. 1-14, and frontispiece. 1922.—This paper is published as part of the Contributions to the Knowledge of the Orchid Flora of Brazil under the joint authorship of R. SCHLECHTER and F. C. HOEHNE. In the present paper, however, the senior author alone treats of an orchid collection made in the state of São Paulo, Brazil, by Alexandre Curt Brade. Much additional information is given concerning species previously described and the following new genera, species, and varieties are characterized: *Habenaria Bradei*, *H. polyrhiza*, *Pogonia paulensis*, *P. fragrans*, *Vanilla angustipetala*, *Pelexia septrum*, *P. laminata*, *Cyclopogon graciliscapa*, *C. Bradei*, *C. iguapensis*, *C. saxicolus*, *C. paulensis*, *C. multiflorus*, *Sarcoglottis tenuis*, *Stenorrhynchus Bradei*, *Craniches Bradei*, *Physurus longicalcaratus*, *Pseudostelis* n. gen., *P. spiralis* (*Pysosiphon spiralis* Ldl.), *P. deregularis* (*Stelis deregularis* Rdr.), *P. Bradei*, *Physosiphon Bradei*, *Pleurothallis Bradei*, *P. subpicta*, *P. Curtii*, *P. transparens*, *P. Dryadum*, *P. sororcula*, *P. iguapensis*, *P. Alexandri*, *Octomeria similis*, *O. iguapensis*, *O. Bradei*, *O. gracilis* Lodd. var. *paulensis*, *O. Alexandri*, *Fractiunguis* n. gen., *F. reflexa* (*Hexisea reflexa* Reichb. f.), *F. brasiliensis*, *Epidendrum Alexandri*, *E. iguapensis*, *Eulophia longifolia* (HBK.) Schltr. var. *flavescens*, *Promenaea paulensis*, *Dipteranthus Bradei*, *Dichaea Cogniauxiana*, *Campylocentrum pubirachis*.—E. B. Payson.

2217. SCHNEIDER, CAMILLO. Notes on American willows, XII. *Jour. Arnold Arboretum* 2: 61-121. 1921 [1922].—This article concludes the series of papers on American willows by this author [see Bot. Absts. 1, Entries 801, 813; 3, Entries 1838, 1839; 4, Entries 1769, 1770; 7, Entries 1490, 2238, 2239; 8, Entry 741; 11, Entry 3236].—It starts with a systematic enumeration of the sections, species, varieties, and forms of American willows; 116 species belonging to 23 sections are enumerated. This is followed by remarks on the hybrids of American willows hitherto observed and by remarks on the geographical distribution of American willows which consist chiefly of an enumeration under each state, province, or country of the species known to occur there. Analytical keys to the species of American willows form the 4th part of the article; 3 keys are provided, 1 for the determination of staminate specimens, 1 for pistillate specimens, and 1 for leaf specimens. An index to all the sections, species, varieties, and forms mentioned in the 12 papers constituting the series concludes the article. The following new names and combinations are proposed: *Salix arctica* f. *diplodictya* (Trautv.) S. Rebbiana f.

luxurians (Fern.) f. *capreifolia* (Fern.), var. *projecta* (Fern.), *S. pedicellaris* f. *tenuescens* (Fern.), *S. Scouleriana* f. *poikila* (Schneid.), \times *S. Glatfelteri* (*S. amygdaloides* \times *nigra*), \times *S. Grayi* (*S. argyrocalyx* \times *planifolia*), \times *S. gaspeensis* (*S. brachycarpa* \times *chlorolepis*), and sect. *Mexicanae*.—Alfred Rehder.

2218. SCHULZ, O. E. *Cruciferae-Brassicaceae (pars prima)*. Das Pflanzenreich Heft 70. (IV, 105). 290 p., fig. 1-35. 1919.—In the present part the author treats the first 2 subtribes of the *Brassicaceae*, namely the *Brassicinae* and the *Raphaninae*. An extensive bibliography is included of papers dealing with the taxonomy, morphology, and anatomy of a larger or smaller number of species of these 2 subtribes. There is presented also a concise account of the general vegetative characteristics, the anatomy, the floral structure, the pollination, and the structure of the fruits, seeds and embryos of the plants considered in this paper. The *Brassicaceae* find their center of distribution in the Mediterranean region. In the western part of this region occur many highly differentiated and mostly monotypic genera. All the species of the 2 subtribes are native to the old world. Twenty-eight genera receive recognition and are treated in great detail. Keys are given to the subtribes, genera, and species. For each species a bibliography is given which includes the synonymy of the species; a lengthy description and statement of geographical distribution with the citation of some specimens also occurs. The principal genera treated are *Brassica* with 33 species, *Erucastrum* with 15, *Sinapis* with 8, *Diplotaxis* with 19, *Raphanus* with 8, and *Crambe* with 19. The following new species and specific combinations occur: *Brassica atlantica* (*B. oleracea* L. var. *insularis* (Moris) subvar. *atlantica* Coss.), *B. cadmea* v. Heldreich ms., and *Sinapodendron palmense* (*Brassica palmensis* O. Ktze). In addition to these there are a very great number of new varieties and new varietal combinations as well as a smaller number of other subspecific novelties.—E. B. Payson.

2219. SMITH, CHARLES PIPER. *Studies in the genus Lupinus. VII. L. succulentus and L. niveus*. Bull. Torrey Bot. Club. 49: 197-206. Fig. 75-78. 1922.—For North American annuals and biennials, outside of a few Mexican and Costa Rican species, 6 groups are recognized: *Stiversiani*, *Succulenti*, *Sparsiflori*, *Micranthi*, *Concinni*, and *Subcarnosi*; a key is given distinguishing between these groups. In the *Succulenti*, *Lupinus succulentus* Dougl. is used for the plant commonly known as *L. affinis* Agardh, a name which belongs to another species. *L. succulentus* Layneae and *L. succulentus* Brandegeii are described as new varieties. Under the *Micranthi* only *L. niveus* Wats. is treated in this paper.—P. A. Munz.

2220. THARP, B. C. *Commelinantia*, a new genus of the Commelinaceae. Bull. Torrey Bot. Club 49: 269-275. Pl. 10-11. 1922.—*Commelinantia* n. gen. is published for *C. anomala* (Torr.) n. comb., based on *Tradescantia anomala* Torr.—P. A. Munz.

2221. WEATHERBY, C. A. A new species of *Eleocharis* from Massachusetts. Rhodora 24: 23-26. 1922.—*Eleocharis fallax* n. sp., from Cape Cod, Massachusetts, an isolated northern representative of *E. arenicola* Torr. (South Carolina to California and Guatemala), *E. montana* (HBK.) R. & S. (tropical America), *E. Dombeyana* Kunth (Andes from Ecuador to Bolivia), and *E. truncata* Schlecht. (Mexico) are discussed and their diagnostic characters presented in a key.—M. L. Fernald.

2222. WIEGAND, K. M. *Carex laxiflora* and its relatives. Rhodora 24: 189-201. 1922.—This is a monographic revision of the group. The following are described and discussed: *C. albursina* Sheldon, *C. blanda* Dewey, *C. laxiflora* Lam., *C. ormostachya* n. sp., *C. crebriflora* n. sp., *C. ignota* Dewey, *C. anceps* Muhl., *C. striatula* Michx., *C. styloflexa* Buckley, *C. styloflexa* var. *fusiformis* (Chapm.) n. comb. based on *C. fusiformis* Chapm., *C. styloflexa* var. *remotiflora* n. var., *C. leptonervia* Fernald.—M. L. Fernald.

2223. WIEGAND, K. M. Notes on some East-American species of *Bromus*. Rhodora 24: 89-92. 1922.—Keys are given to the introduced species of the *Bromus secalinus* affinity and

to the native species of the *B. ciliatus* group. The following are discussed: *B. secalinus* L., *B. secalinus* f. *hirtus* (F. Schultz) n. comb. based on *B. mutabilis* ♂ *hirtus* F. Schultz, *B. racemosus* L., *B. commutatus* Schrad., *B. hordeaceus* L., *B. hordeaceus* f. *leptostachys* (Pers.) n. comb. based on *B. mollis* β. *leptostachys* Pers., *B. ciliatus* L., *B. ciliatus* f. *denudatus* n. f., *B. ciliatus* f. *laeviglumis* (Scribn.) n. comb. based on *B. ciliatus laeviglumis* Scribn., *B. altissimus* Pursh, *B. altissimus* f. *incanus* (Shear) n. comb. based on *B. purgans incanus* Shear, *B. purgans*, *B. purgans* f. *laevivaginata* n. f. and f. *glabriflorus* n. f.—M. L. Fernald.

2224. WIEGAND, K. M. Variations of *Carex annectans*. *Rhodora* 24: 73-74. 1922.—The 2 plants originally proposed by Bicknell as *Carex xanthocarpa* (1896) and *C. xanthocarpa annectans* (1896) prove to have well defined ranges, and are maintained as geographic varieties. The earlier *C. xanthocarpa* Degland (1807) necessitates the taking up of *C. annectans* Bicknell (1908) and the new combination *C. annectans* var. *xanthocarpa* (Bicknell) Wiegand.—M. L. Fernald.

BOTANICAL ABSTRACTS

A monthly serial furnishing abstracts and citations of publications in the international field of botany in its broadest sense.

UNDER THE DIRECTION OF

THE BOARD OF CONTROL OF BOTANICAL ABSTRACTS, INC.

AGRONOMY

C. V. PIPER, *Editor*

MARY R. BURR, *Assistant Editor*

(See also in this issue Entries 2343, 2403, 2404, 2412, 2416, 2422, 2436, 2437, 2442, 2494, 2508, 2622, 2674, 2675, 2680, 2687, 2693, 2792, 2793, 2795, 2821, 2822, 2827, 2829, 2831, 2833, 2839, 2842, 2891)

2225. ANONYMOUS. A novel method of growing potatoes. Agric. Gaz. New South Wales 33: 778. 1 fig. 1922.—Young plants were clipped and transplanted after having been planted some time. One tuber gave a crop of 126 pounds.—*L. R. Waldron*.

2226. ANONYMOUS. Efwatakala grass (*Melinis minutiflora*), how it eradicated plantation weeds. Tropic. Life 18: 128. 1922.—The article is a quotation from an account in the Rev. Agric. Tropic, San Salvador of a farmer's experience in eradicating Johnson grass, *Holcus halapense*, from his cultivated fields. Finding it almost impossible to destroy the Johnson grass by cultivation he seeded the fields to Efwatakala grass and the latter occupied the ground so fully that the Johnson grass was killed out. He then proceeded to destroy the Efwatakala by cultivation. Eradication of this grass was easy on account of its fibrous root system. This method of eradicating persistent weeds would appear of considerable value in tropical and sub-tropical regions. Note: The grass *Melinis minutiflora* is known as "Molasses grass" in the United States and as "Gordura grass" in Brazil where it is abundant. [See also Bot. Absts. 11, Entry 3298.]—*H. N. Vinall*.

2227. ANONYMOUS. Field experiments with peanuts. Grafton and Wollongbar experiment farms, 1921-22. Agric. Gaz. New South Wales 33: 793-794. 1922.—Peanut varieties used were Chinese, White Spanish, and Valencia. Planting was done late in September and the crop was harvested in March and April. The maximum yield of 2,165 pounds of nuts per acre was secured from White Spanish at Wollongbar. There is very little local demand for the crop.—*L. R. Waldron*.

2228. ANONYMOUS. Kieselsäure als Phosphorsäureersatz. [Silicic acid as a substitute for phosphoric acid.] [Rev. of: LEMMERMANN, OTTO. Die ertragsteigernde Wirkung der Kieselsäure bei unzureichender Phosphorsäuredüngung. Sonderabdruck a. d. Zeitschr. Pflanzenernähr. u. Düng. 8 vo, 72 p. 1922.] Wiener Landw. Zeitg. 72: 395-396. 1922 [1923].—Silicon in certain forms appears to be directly utilized by the plant, and an increase of yield is noted particularly

when the fertilizer is somewhat deficient in phosphoric acid but potash and nitrogen are supplied in the requisite quantities. The most favorable form of silicon was colloidal silicic acid; phonolith was without action and kieselguhr was injurious. The investigation was carried on in quartz sand and soil cultures, and the results confirmed in the field. The action of silicic acid fertilizer is held to be directly on the plant, as opposed to the conclusion first arrived at at Rothamsted that phosphates are thereby only rendered more readily assimilable. The importance of these findings, in view of the shortage of phosphates in central Europe, is emphasized.—*F. Weiss.*

2229. ANONYMOUS. *Verslag over het jaar 1921.* [Report for the year 1921.] Dept. Landb. Suriname 94 p. Paramaribo, 1922.—At the experiment station 297 hectares were planted in coffee. The growth of the plants was generally good, and the seed beds furnished sufficient material. A part of the land was at first planted with bacove as shade, later followed by coffee. The cocopalm plantation suffered considerably from heart rot. The breeding of coffee and cocoa is of much importance, and large numbers of budded and grafted plants are available. Fermentation of coffee bean shows some difficulties: instead of being complete in 4 days, the process is sometimes not concluded in 6 days or even more. By the addition of sour milk, however, fermentation may be finished in 1-3 days, and this new process is followed by several plantation owners.—Further short reports are given on malachra, okra, *Hibiscus cannabinus*, *H. sabdariffa*, rice, corn, bananas, citrus fruits, and forestry activities.—*J. C. Th. Uphof.*

2230. ARNY, A. C. *Border effect and ways of avoiding it.* Jour. Amer. Soc. Agron. 14: 266-278. 1922.—Experiments show that the removal of border rows is necessary in order to secure reliable results. However, under certain conditions this operation may not be necessary. Careful experimentation over a period of years is the only way to determine this point.—*F. M. Schertz.*

2231. BATTEN, E. T. *Experiments with cotton and peanuts.* Virginia Agric. Exp. Sta. Bull. 229. 22 p., 5 fig. 1922.—The 8 years' experiments were conducted at Holland, Virginia. Lime was found to be beneficial and should be applied to all soils in the locality once in 4 years. Fertilizer should not be applied directly to peanuts except on the poorer soils where acid phosphate and cottonseed meal, or other organic source of nitrogen, are recommended. Cotton should receive nitrogen, phosphorous, and potash, especially the latter. Nitrogen should be used sparingly on the richer soils and must be balanced with phosphorous to insure early maturity. A complete fertilizer, analyzing 4-8-2, is profitable for the corn crop. Soy beans should be included in the rotation, either as a separate crop or planted in the corn.—*F. D. Fromme.*

2232. BAUER, FRANZ. *Ueber Kunstdüngung.* [Use of artificial fertilizers.] Wiener Landw. Zeitg. 72: 78-79. 1 fig. 1922.—Practically all of Austria's needs for artificial fertilizers, must be met by importation. Owing to the high price of imported fertilizer, and to prevent the sale of worthless products, the manufacture of a mixed fertilizer has been undertaken under state auspices. A diagram showing the artificial fertilizers which may or may not be mixed before application, and recommendations for rates of application are given.—*F. Weiss.*

2233. BEAVEN, E. S. *Trials of new varieties of cereals. Part II.* Jour. Ministry Agric. Great Britain 29: 436-444. 1922.—A description is given of the "half-drill-strip" method of sowing cereals designed to reduce the probable error of the results of trials of new races.—*M. B. McKay.*

2234. BIDWELL, GEORGE L., LESLIE E. BOPST, and JOHN D. BOWLING. *A physical and chemical study of milo and feterita kernels.* U. S. Dept. Agric., Bull. 1129. 8 p. 1922.—On the whole, kafir, milo, and feterita resemble one another in composition and appearance. Aside from their food value for man and domestic animals, they may possibly be used com-

mercially in the manufacture of starch, sirup, alcohol, and oil, when proper machinery and processes have been devised, but probably not for malting purposes.—*J. T. Buchholz.*

2235. BLAIR, A. W. **Agricultural and commercial values of nitrogenous plant foods.** Jour. Amer. Soc. Agron. 14: 162-167. 1922.—No greater returns have been received from the use of organic forms of nitrogen than from inorganic forms, and it has cost the farmer more. The ready availability of nitrate has had much to do with the larger yields where nitrate was used. The commercial values of organic materials should be made more in accordance with their agricultural values.—*F. M. Schertz.*

2236. BLAKELY, W. F. **Weeds of New South Wales.** Agric. Gaz. New South Wales 33: 815-817. 1 fig. 1922.—Tumbling mustard (*Sisymbrium altissimum*) was first collected at Cudal in 1920. The plant is figured and described, and methods of control are suggested.—*L. R. Waldron.*

2237. BROWN, B. A. **Plot competition with potatoes.** Jour. Amer. Soc. Agron. 14: 257-258. 1922.—Experiments show that apparently yields of potatoes are not influenced by competition between single-row plots.—*F. M. Schertz.*

2238. BROWN, B. E. **Effect of borax in fertilizer on the growth and yield of potatoes.** U. S. Dept. Agric. Bull. 998. 8 p. 1922.—Results of these experiments, conducted on Caribou loam, Aroostook County, Maine, showed that definite injury occurred with an application as low as 5 pounds of borax per acre when the borax was put in the furrows and the planting done immediately. Some of the reactions with borax were: failure of the seed piece to germinate; killing of sprouts; absence of roots on seed pieces; general weakness of plants which come through the ground; bleaching of the foliage; poor stand and low yields.—*J. T. Buchholz.*

2239. CHALONS. **Beiträge zur Sorteneinteilung von Weizen und Roggen unter besonderer Berücksichtigung der Halmanordnungen.** [Contribution to the variety separation of wheat and rye, with special reference to blade arrangement.] Landw. Jahrb. 57: 667-677. 1922.—On analyzing varieties of winter and summer wheats and rye, the author demonstrated that the thickness of the spikelet is subject to great variations within the individual plants and therefore can not be used as a basis of variety differentiation, as suggested by Moebins and Derlitzki. The size and arrangements of blades, however, are of importance, especially between the main blade and that of the second order.—*S. A. Waksman.*

2240. CHAMBLISS, CHAS. E., and J. MITCHELL JENKINS. **Some new varieties of rice.** U. S. Dept. Agric. Bull. 1127. 17 p., 4 pl. 1923.—“This bulletin includes a description of the rice plant, and a botanical and agronomic description of 7 new varieties that have been developed in the course of cooperative experiments at the Rice Experiment Station, Crowley, Louisiana, and of 4 varieties now widely grown in this country. The agronomic performance and adaptation of each variety, including a full description of the conditions under which the experiments were conducted, are discussed in detail. The commercial value of the milled rice of the new varieties from a culinary standpoint is indicated.”—*J. T. Buchholz.*

2241. COLLINS, S. H., and B. THOMAS. **The sugars and albuminoids of oat straw.** Jour. Agric. Sci. 12: 280-286. 1922.—“Fine weather” during harvesting is essential for obtaining high percentages of sugar which gradually disappears from straw after harvest. The loss is very rapid if straw becomes damp. The amount of albuminoids in oat straw is largely conditioned by the amount of nitrogen in the soil, but the amount of grain produced is also a factor. By proper management, oat straw of much higher feeding value can be obtained.—*V. H. Young.*

2242. CONNER, S. D. **Nitrogen in relation to crop production in the middle west.** Jour. Amer. Soc. Agron. 14: 179-182. 1922.—The nitrogen problem is the most important soil

fertility problem before the corn belt farmers. Average Indiana soils have lost 20-40 pounds of nitrogen per acre per year for the last half century. Legumes and manure are needed. Much of the profit in the use of lime, phosphate, and potash is in the beneficial effect on legumes.—*F. M. Schertz.*

2243. DAVIDSON, J. D., and R. G. STAPLEDON. **Failure of Black Yeo oats in Glamorgan in 1921.** Jour. Ministry Agric. Great Britain 29: 465-469. 1922.—On 10 farms spring-sown Black Yeo oats, with seed from the same source, failed in spite of the fact that the seed was quite normal in appearance, gave no evidence of defect, and on test had germinated 97 per cent. The failure was due in part to unfavorable climatic conditions and to the fact that the variety is a winter variety; but chiefly because the seed were defective in some physiological respect which rendered them particularly susceptible to the influence of drought. This defect was strikingly revealed by a differential germination test conducted in soil in pots in which normal, half, quarter, and double waterings were used. The results secured indicate that differential germination "tests conducted under conditions less favorable to germination and growth than ordinary conditions are competent to reveal defects in a sample that might be overlooked if only the ordinary test was conducted and to bring out such defects more prominently."—*M. B. McKay.*

2244. DAVIDSON, JEHIEL. **The effect of nitrates applied at different stages of growth on the yield, composition and quality of wheat.** Jour. Amer. Soc. Agron. 14: 118-122. 1922.—The effectiveness of nitrates in increasing yields consistently decreases as the time of application approaches the stage of heading. The effectiveness of nitrates in increasing the protein content ($N \times 5.7$) of the grain increases as their effectiveness in increasing the yield decreases.—*F. M. Schertz.*

2245. ELLETT, W. B., and T. K. WOLFE. **The effect of fertilizers on yield and market conditions of corn.** Jour. Amer. Soc. Agron. 14: 153-158. 1922.—Under the experimental conditions it appeared that phosphates and stable manures are the most valuable materials used for increasing the yield and quality of the corn crop. Organic matter in the form of green manure, as well as in the form of stable manure, has been valuable in increasing yield.—*F. M. Schertz.*

2246. FENTON, E. W. **Spotted medick.** Jour. Ministry Agric. Great Britain 29: 643-648. 2 fig. 1922.—Spotted medick (*Medicago arabica* All.; *M. maculata* Sibth.), a troublesome weed in meadow and pasture lands, has apparently been recently introduced into certain areas in wool, shoddy, and wool cleanings. It may be eradicated by dusting—preferably in early spring—with sulphate of ammonia at the rate of 5-12 ounces of the dust to 8 square yards of ground surface.—*M. B. McKay.*

2247. GARVER, SAMUEL. **Alfalfa root studies.** U. S. Dept. Agric. Bull. 1087. 28 p., 19 fig. 1922.—Studies were made at Redfield, South Dakota, on 7 varieties of alfalfa seeded at the same time and grown under the same soil moisture conditions. The root systems of the least hardy forms of purple-flowered alfalfa may be distinguished from the most hardy hybrid and yellow-flowered alfalfas with accuracy. The intermediate forms, however, are not sufficiently distinct to be distinguishable from one another or invariably from some forms of the non-hardy or of the yellow-flowered alfalfas. Factors tending to produce modification of tap roots in alfalfa are soil, climate, cultural treatment, and injuries.—*J. T. Buchholz.*

2248. GERICKE, W. F. **Studies on the effect of nitrogen applied to oats at different periods of growth.** Jour. Amer. Soc. Agron. 14: 312-320. 1922.—The paper reports the effect of N applied to oats at different periods of growth, on time of maturing of the plants, on the height and number of stalks produced, on production of dry matter, and on the protein content of the grain.—*F. M. Schertz.*

2249. GRAEBER, L. F. Scarification as it affects longevity of alfalfa seed. Jour. Amer. Soc. Agron. 14: 298-302. 1922.—The data indicate clearly that scarification exposes alfalfa seed to factors which cause a far more rapid decrease in viability than normally obtains with the untreated seed. To obtain best results, seed should be scarified shortly before seeding.—*F. M. Schertz.*

2250. HASKELL, S. B. A study of present and future supplies of fertilizer nitrogen. Jour. Amer. Soc. Agron. 14: 167-178. 1922.—A general review of the nitrogen situation is presented.—*F. M. Schertz.*

2251. HAYES, H. K., and A. N. WILCOX. The physiological value of smooth-awned barleys. Jour. Amer. Soc. Agron. 14: 113-118. 1922.—Comparative yield tests and comparative studies in threshing yard-square plots and also rod or head rows. Three men threshed and cleaned 120 samples per hour, recording weights of both straw and grain. A detailed description of the machine is given together with drawings.—*F. M. Schertz.*

2252. JENSEN, O. F. and M. E. OLSON. A small grain nursery thresher. Jour. Amer. Soc. Agron. 14: 110-112. 1922.—A small grain thresher is described which the authors find convenient in threshing yard-square plots and also rod or head rows. Three men threshed and cleaned 120 samples per hour, recording weights of both straw and grain. A detailed description of the machine is given together with drawings.—*Roland McKee.*

2253. KEMP, W. B. An index for measuring the performance of wheat varieties and strains. Jour. Amer. Soc. Agron. 14: 258-265. 1922.—The index is an aid to measuring the progress that has been made in variety testing and selection or breeding of wheat and other small grains.—*F. M. Schertz.*

2254. KERLE, W. D. The Clarence River maize growing contest. Agric. Gaz. New South Wales 33: 779-782. 1922.—Nine farmers competed, the crops being grown in each case under comparable conditions upon 2 farms. The plots securing 1st prize were planted to a local variety and gave an average yield of 94 bushels per acre.—*L. R. Waldron.*

2255. KNIERTEM, W. VON. Düngungsversuche mit verschiedenen neueren Stickstoffdüngemitteln. [Fertilizer experiments with various new nitrogenous fertilizers.] Mittell. Deutsch. Landw. Ges. 37: 654-655. 1922.—The writer reports the results of a test with urea, ammonium sulphate, and ammonium sulphate-nitrate on potatoes and beets. All plots received equal amounts of nitrogen in the above mentioned forms. The plot receiving urea gave the highest yield. Similar results were secured with sugar beets. In view of the high nitrogen content of urea (46 per cent) its use is advised since small quantities cover considerable areas.—*A. J. Pieters.*

2256. LAMBOURNE, J. Local production of gingelly as a catch crop. Malayan Agric. Jour. 10: 94-99. 1922.—It is shown that *Sesamum indicum* can be grown as a crop in the Malay Peninsula. The seed sown was of mixed races, which reduces the value of the experiment; it is not even clear that early races only were in the crop, though early races were present as the period from sowing to harvesting was 109 days. The constants of the oil obtained are given.—*I. H. Burkill.*

2257. LING, ARTHUR R. Sugar technology. [Rev. of: (1) DEERR, NOËL. Cane sugar: A text book on the agriculture of the sugar cane. The manufacture of cane sugar and the analysis of sugar house products. 2nd ed., rev. and enlarged, viii + 644 p., 29 pl. Norman Rodger: London, 1921. (2) JONES, LLEWELLYN, and FREDERIC I. SCARD. The manufacture of cane sugar. 2nd ed., xix + 481 p., 270 pl. Duckworth & Co.: London, 1921. (3) MURKE, F. Condensed description of the manufacture of beet sugar. v + 175 p. John Wiley and Sons: New York; Chapman and Hall: London. 1921.] Nature 110: 4-5. 1922.—The reviewer

regards the first 2 books as comprehensive and authoritative. The 3rd is intended for factory superintendents, etc., and scarcely desirable as an elementary textbook on the subject.—O. A. Stevens.

2258. LIPSCHÜTZ, H. Versuchsergebnisse mit Phosphathumus und Stickstoffhumus. [Experiments with phosphorus- and nitrogen-containing humus.] Wiener Landw. Zeitg. 72: 19-21. 1921.—The use of these fertilizers is claimed to have given greater yields of potatoes, mangels, and wheat, even in an abnormally dry year like 1921, than were obtainable by the use of mineral fertilizers alone. The particular value of these humus fertilizers is ascribed to the contained organic matter and soil-modifying bacteria.—F. Weiss.

2259. MCCOOL, M. M., and PAUL M. HARMER. Effect of fertilization on the growth of sugar beets on some Michigan muck soils. Jour. Amer. Soc. Agron. 14: 228-234. 1922.—A study is reported on the effect of fertilizers on tonnage, sugar content, and percent of purity of beets.—F. M. Schertz.

2260. MAKIN, R. N. Farmers' experiment plots. Maize experiments, 1921-22. South coast. Agric. Gaz. New South Wales 33: 790-792. 1922.—Trials for grain yields were conducted on 5 private farms. The maximum yield, 150 bushels per acre, was secured from Funk's yellow dent corn. Superphosphate gave best results in manurial trials.—L. R. Waldron.

2261. MARTIN, JOHN H. Experiments with cereals on the Belle Fourche Experiment Farm Newell, South Dakota. U. S. Dept. Agric. Bull. 1039. 72 p., 22 fig. 1922.—Experiments conducted on dry land for 12, and on irrigated land for 8, years are reported. The soil is a heavy, impervious clay known as Pierre clay. The seasonal precipitation is an important factor influencing the yield of grain. The best varieties of wheat, oats, and barley have yielded fairly well on dry land, but with complete or partial failure in some years. Varieties recommended for growing on dry land are: spring wheat,—Kubanka, Marquis; winter wheat,—Turkey, Kharkof; oats,—Kherson, Sixty-Day; barley,—White Smyrna, Hannechen. Winter wheat has produced higher average yields than spring wheat, but is uncertain due to winter-killing and soil blowing. The Kubanka is the highest yielding spring variety. On irrigated land the same wheat varieties are recommended. Winter wheat gives a slightly higher average yield than spring wheat. Other varieties recommended for irrigated land are: oats,—Silvermine, White Russian; barley,—Chevalier, Trebi; flax,—Damont, Reserve. Rate of seeding experiments are also reported, and recommendations made for the several varieties.—J. Lincoln Cartledge.

2262. MÜLLER, H. C., UND E. MOLZ. Versuche zur Erhöhung der Produktionskraft der Saatkartoffel. [Experiments on the increase of productivity of seed potatoes.] Landw. Jahrb. 57: 679-706. 1922.—Seed potatoes harvested when the vines were still green were distinguished by uniform germination, earlier growth, and larger yields in comparison with those harvested when the vines had died down. Plants injured in early development gave tubers with weakened productivity. Moderate shading produced results similar to early harvesting, the tubers being more productive than from plants grown in the light. Good light also increased the setting of tubers, while insufficient light diminished it and brought about more abundant leaf growth. Light and transpiration relations of the plant, which modify the starch content of the tubers, have an important influence upon the productivity of the seed potato. Also size of the seed potato, other things being equal, influences the yield.—S. A. Waksman.

2263. O'DWYER, MARGARET H. Preliminary report on the nutritive value of certain Australian grasses. Proc. Linn. Soc. New South Wales 46: 239-251. 1921.—Material was taken and air dried at (a) medium stage, halfway between beginning of shoot and flowering; (b) at early flowering; (c) when seed was quite set. Material was weighed at the farm as soon

as cut; this is responsible for certain inaccuracies due to lack of equipment. Rapid changes of material, especially those produced by wilting, are discussed. For analysis samples were ground fine enough to pass a 1 mm. sieve and stored in air tight bottles in the dark. The methods of the Association of Official [American] Agricultural Chemists (1919), were followed in the main. The effect of soil, season, and elevation was noted. Table 1 presents analyses of 3 specimens of *Danthonia semiannularis* Labill., 5 of *Schedonorus Hookerianus* Benth., and 2 of *Panicum prolutum* from different localities and soils. It also gives stage of growth, moisture content, ash, crude protein, true protein, crude fiber, ether extract, pentosans, carbohydrates, and albuminoid ratio. Table 2 shows the protein content at different stages of growth in 7 specimens of *Schedonorus Hookerianus*, 1 of *Panicum decompositum* R. Br., 4 of *P. prolutum*, 2 of *Eragrostis leptostachya*, 3 of *Danthonia semiannularis*, 1 of *D. pilosa* (?) R. Br., and 1 of *Pollinia fulva* Benth. Table 3 gives the protein content in the flowers of these species.—*Eloise Gerry*.

2264. PAERELS, J. J. Coirvezel. [Coconut fiber.] *Cultura* 34: 305-308. 1922.—After the settlement of the Hollanders in the Malayan Archipelago, the coconut fiber industry increased slightly until 1851, when, during the London exhibition, this product became better known. In Java, natives beat a section of the coat of the fruit until it becomes soft. This mass of fiber is soaked in water for 12 hours to loosen the "latek" or solid matter between the fibers and epidermis. After further beating the shortest fibers are removed by hand, then the entire mass is wrung. The fiber is dried in the sun, rolled by hand on a board, and later sorted into 2 types, both suitable for the production of rope. In Ceylon, on the other hand, a fermentation process is generally followed.—*J. C. Th. Uphof*.

2265. PAERELS, J. J. Vezel agave. [Fiber agave.] *Cultura* 74: 381-387. 1922.—The growing of agave for fiber is being developed in Dutch East India. *Agave sisalina*, *A. cantala*, and *A. fourcroydes* are cultivated. Harvesting in Java begins 3-4 years after the 2-year old plants have been planted. The older leaves are better for fiber production. Vertical leaves are not harvested, but those growing at an angle of 45° or more are cut. The dry period is the best for harvesting. In Java 3-4 cuttings are made a year, about 30 leaves to the plant are gathered, and 1000-1250 kgm., sometimes 2000, of fiber per bouw [0.70 hectare] are harvested.—*J. C. Th. Uphof*.

2266. PAWLIK, R. Ueber die Setzweite der Kartoffeln. [Concerning the planting distance for potatoes.] *Wiener Landw. Zeitg.* 72: 97. 1922.—Potatoes spaced about 20-30 cm. apart gave higher yields than those more closely or distantly planted. This requires about 20 bushels of seed per hectare.—*F. Weiss*.

2267. ROBERTSON, G. S. Field experiments with rock phosphates and basic slags. *Jour. Ministry Agric. Great Britain* 29: 519-530, 600-605. 10 fig. 1922.—"Rock phosphates produce exactly the same type of improvement in the quality of the hay crop and the pasture as the most soluble types of open hearth basic slag, and they are quite as effective in this respect. The open hearth low-soluble fluorspar slags are not so consistent in their behavior. The evidence suggests that the less soluble types do not improve the hay crops to the same extent as the high-soluble slags."—*M. B. McKay*.

2268. ROSSEM, C. VAN. De nauwkeurigheid van bemestingsproeven bij rijst, alsmede overzicht van de uitkomsten van de bemestingsproeven met stickstof- en fosforzuurhoudende kunstmest, genomen in de jaren 1911-1917. [The accuracy of fertilizer tests with rice, with a survey of the results of fertilizer tests with artificial fertilizers containing nitrogen and phosphoric acid.] *Dept. Landb. Nijv. en Handel [Nederland.-Indië] Alg. Proefsta. Landb. Mededeel.* 4. 33 p. 1920.—Errors due to soil variation are classed as systematic. If all observations are of equal accuracy, the arithmetic mean is the most probable value. Because the mean error decreases slowly with increasing numbers of observations, it is more economical to increase reliability by refining methods than by increasing the number of observations.

The mean error is a measure of the accuracy of a result, but not of its correctness. The latter depends also on the presence or absence of systematic errors. Deviations more than 3 times the mean error indicate systematic factors. Differences in experiments are considered significant if 3 times their mean error (4.5 times their probable error). In a test with 10 replications a difference must be as great as 6 pikols wet padi, and with 5 replications 8 pikols per bouw in order to be significant [1 pikol wet padi per bouw = 78 pounds per acre, or about 39 pounds milled rice per acre]. The mean error is independent of the mean yield. These conclusions are based upon 4 years' tests. In only 2 cases has potassium deficiency been demonstrated, and in these additions of potassium did not pay. The number of cases found of soils deficient in nitrogen equalled the number deficient in phosphorus, but the addition of double superphosphate to soils poor in phosphorus gave greater increases than the addition of equal quantities of ammonium sulphate or ammonium chloride to soils poor in nitrogen. In the district of Rembang an increased yield of 32 pikols per bouw resulted from adding 1 pikol of double phosphate per bouw.—*Carl Hartley.*

2269. RUZICKA, CHARLES H. Williston substation report 1914-1920. North Dakota Agric. Exp. Sta. Bull. 158. 104 p., 17 fig. 1922.—The results presented in many cases cover a period of 13 years. It is not evident that durum wheats have been significantly more resistant to drought and heat damage than the leading wheats of other groups.—In a rate-of-seeding test made with common wheat and extending over 8 years, yields from 4-, 5- to 6-peck rates were nearly identical.—A date-of-seeding trial was conducted with wheat for 4 years. Seeding was done April 15, May 1, and May 16. The average yields were 34.4, 29.7, and 20.2 bushels per acre, from early seeding to late seeding, respectively.—Phenological notes and weight per bushel are given on different groups of wheat.—Experiments do not warrant planting winter wheat except possibly in special cases.—Experiments were conducted with varieties of oats, barley, flax, and rye. In comparative yields secured from emmer, barley, and oats for a period of years, emmer has yielded 1728, barley 1875, and oats 2045 pounds per acre.—Both proso and millet occasionally have given excellent yields of seed.—Results with buckwheat have generally been negative.—In a 7-year trial of corn varieties, Dakota White Flint ranked 1st with 26.4 bushels, Gehu 2nd with 25.2 bushels, and North-western Dent 3rd with 23.2 bushels per acre.—The bulletin deals with manner, rate, and time of planting and cutting corn and previous treatment of the soil.—Following an ear-row and seed corn plot method for 5 years, yield was only slightly affected but the quality improvement was significant.—Certain varieties of sorgo gave good averages of fodder, but their inferior feed quality makes them an unimportant substitute for corn.—Sudan grass for an average of 6 years yielded 3351 pounds of air-cured hay per acre when sown in drills for cultivation.—Yields from sunflowers grown under dry land conditions were essentially the same as yields secured from corn similarly grown. In a trial of 1 season, sunflowers (irrigated) outyielded corn (irrigated) by 3 tons of green material per acre.—Forage crops from different kinds of millets have been successful only in certain years.—For the 3 years, 1915-1917, brome grass yielded 1528 pounds per acre and slender wheat grass 1253.—Timothy, red clover, and vetch have not been successful.—Results are discussed of extensive rotation experiments with small grains and corn.—Wheat on fall-plowed land plowed 8 inches deep and deep-tilled to a depth of 16-18 inches every 4th year showed only a slightly greater yield than when grown after plowing of medium depth.—It is possible to store in well handled fallow land only from $\frac{1}{3}$ to $\frac{1}{2}$ of the season's precipitation to be available for the succeeding crop. Disking stubble land in the fall after the binder has not shown increased yields over comparison plots treated in the ordinary way. Cultivation to maintain a mulch has evidently had but little effect aside from killing weeds.—Experiments with potatoes have covered a comparison of varieties, size and method of cutting seed tubers, rates and methods of planting, methods of soil treatment, and methods of field selection.—Notes are given on trees and shrubs and certain kinds are recommended. Notes are given on various fruits including crabapples, plums, and bush fruits.—*L. R. Waldron.*

2270. SCHUBERT. Eine bewährte Kartoffelsorte. [A potato variety of proved value.] Wiener Landw. Zeitg. 72: 96. 1922.—The variety Alma has been a consistent leader during 3 years of variety testing at several stations in Tyrol, outyielding in particular the newly introduced English potatoes.—*F. Weiss.*

2271. SCHUBERT, JOSEF S. **Etwas über Sortenwahl und Sortenwechsel im Kartoffelbau.** [Concerning selection of potato varieties.] *Oesterreich. Zeitschr. Kartoffelbau* 2: 1-3. 1922.—The author discusses the distribution of potato culture in Austria from the standpoint of soil types, yield, and varieties grown. He classifies varieties with respect to resistance to blight, scab, and wart diseases.—*F. Weiss.*

2272. SCHUSTER, GEORGE L. **Influence of fertilizers on yield and maturity of soy beans.** *Jour. Amer. Soc. Agron.* 14: 193-197. 1922.—It is the muriate of potash in fertilizers that brings the soy beans to maturity. Manure (3-5 tons per acre) favored early maturity—probably due to the potash contained—and gave the largest yields. In the absence of manure 250 pounds of acid phosphate and 75 of muriate of potash are recommended. Nitrate of soda gives unsatisfactory results with soy beans as to maturity, yield, and financial returns.—*F. M. Schertz.*

2273. SHERWIN, M. E., R. B. ETHERIDGE, AND A. DUNHAM. **A new muck soil problem and its solution.** *Jour. Amer. Soc., Agron.* 14: 212-215. 1922.—The authors discuss a muck soil problem in North Carolina.—*F. M. Schertz.*

2274. SNELLEN, E. **Over het groot-Rijstbedrijf in Ned-Indie.** [Large-scale rice culture in Dutch India.] *West Indië* 7: 71-79. 1922.—The fact that the region requires more rice than it produces has led to experiments with rice culture on a large scale as is done in California. In Surinam, fields were laid off to make possible irrigation and drainage. The experiments though not very successful are being continued. The author reviews an address by van der Veer before the Netherlands-India Association for Industry and Agriculture in the Hague, in which the speaker discussed the possible use of tractors, etc., in the rice fields. The difficulties and the special requirements of machines for successful operation are pointed out.—*A. J. Pieters.*

2275. SPARKS, G. C. **Some phases of wheat culture.** *Agric. Gaz. New South Wales* 33: 775-777. 1922.—A method of mass selection is suggested to be used on the farm. Care is urged to avoid seed injury when treating with formalin and copper sulphate.—*L. R. Waldron.*

2276. THOMAS, R. G. **Present and probable future distribution of wheat, sheep, and cattle in Australia.** *Proc. Roy. Soc. Victoria* 34: 117-127. *Fig. 1-3.* 1922.—The distribution is given by units of 5,000 acres of wheat, 10,000 head of sheep, and 1,000 head of cattle, based on the statistics of the year 1918-1919. Data on rainfall and temperature are also presented.—*Eloise Gerry.*

2277. WENHOLZ, H. **The conservation of fodder in New England.** *Agric. Gaz. New South Wales* 33: 783-789. 1922.—The crops and methods considered are those most profitable in averting stock losses due to drought in the winter season and in preventing a general unthrifty condition of stock. The fodder crops discussed are: cereal hay and straw, alfalfa, clover and sweet clover hay, maize stover, sorghum and Sudan grass hays, corn and sunflower silage, and oats and maize grain. Frequent comparisons are made with practices followed in the U. S. A.—*L. R. Waldron.*

2278. WERBA, KARL. **Versuche mit Phosphathumus.** [Experiments with "phosphathumus."] *Wiener Landw. Zeitg.* 72: 59. 1922.—Experiments with this "colloidal, phosphorus-containing, bacterial fertilizer" on potatoes and sugar beets are reported. Only a slightly larger yield was obtained by applying 15 kgm. of phosphathumus per 100 square m. and no increase with 10 kgm. The dry season of 1921 was unfavorable for the development of bacterial activity, which is claimed to result from the use of this fertilizer.—Phosphathumus was first produced to utilize the surplus of Thomas slag in the iron industry. It is said to contain 8-10 per cent of soluble phosphoric acid, 1 per cent each of potassium oxide and nitrogen, and 15-20 per cent of calcium oxide, besides 1-2 millions of active bacteria per gram capable of

ammonification and nitrification. The claim for the quantity and activity of the bacteria is doubted because of the conditions of manufacture and storage.—*F. Weiss.*

2279. WHITTET, J. N. Winter grasses in the Orange district. *Agric. Gaz. New South Wales* 33: 795-796. 1 fig. 1922.—A comparison of native with seeded pastures showed the decided superiority of the latter. Grasses showing most promise were *Avena elatior*, *Phalaris bulbosa*, and *Bromus inermis*, the last for winter pasture. One hundred milking cows pasturing 3 hours daily for 10 months in 16 acres of *Phalaris bulbosa* and *Dactylis glomerata* failed to keep the grass pastured down.—*L. R. Waldron.*

2280. WILLIAMS, C. G. The nitrogen inventory as affected by livestock vs. grain farming. *Jour. Amer. Soc. Agron.* 14: 159-162. 1922.—The author points out that apparently a moderate increase in the nitrogen content of the soil and a slightly larger yield of crops result from the live stock system than from the grain system.—*F. M. Schertz.*

2281. ZAILER, VIKTOR. Vergleichende Anbauversuche mit deutschen und schottischen Kartoffelsorten in Admont. [Comparative tests with German and Scotch potatoes in Admont.] *Oesterreich. Zeitschr. Kartoffelbau* 2: 17-19. 1922.—The German variety Jubel ranked 1st in every test on account of its resistance to disease, drought, and heat. The starch content and keeping quality of all potatoes was depressed owing to the short growing season. Varieties producing numerous small tubers had a higher starch content than those producing a few large ones.—*F. Weiss.*

2282. ZAVITZ, C. A. Grains grown in combination for grain production. *Jour. Amer. Soc. Agron.* 14: 225-228. 1922.—Barley, oats, wheat, and peas were grown separately and in combination. The greatest influence for high production was exerted by barley and the second highest by oats. If the proper varieties and proportions of barley and oats are grown together under favorable conditions a comparatively high yield of the mixed grain may be expected.—*F. M. Schertz.*

FACTORS, MEASUREMENTS

2309. HORTON, ROBERT E. Results of evaporation observations. Monthly Weather Rev. 49: 553-566. 1921.—A tabular statement of evaporation at 28 localities for various periods between 1913 and 1920 is given. The stations are chiefly located in the semi-arid plateau section from Texas to the Canadian line.—*E. N. Munns.*

2310. PEARSALL, W. H. A suggestion as to factors influencing the distribution of free-floating vegetation. Jour. Ecol. 9: 241-253. 4 fig. 1922.—The examination of some 400 complete analyses and several thousand partial analyses of European surface waters as well as the consideration of other data brings out the fact that calcareous waters tend to produce greater quantities of plankton than the sea. Such waters seem to be better nutrient media on account of their larger proportions of nitrates, phosphates, and silica. The mass of plankton must be, according to this hypothesis, some function of the limiting ion (or ions). Thus the sea, with 3.5 per cent of dissolved solids, may be a decidedly limited medium for plant growth because of the small amounts of phosphates and nitrates.—*Geo. D. Fuller.*

2311. TOBLER, F. Die Wohlbecker Flechten-Standorte. [The lichen-habitats about Wohlbecker.] Hedwigia 63: 7-10. 1921.—The Zoological Garden of Wohlbecker is a peculiar habitat with respect to the presence of old oaks and beeches, which are rare in the surrounding area. Since 1885, when Lahm completed his extensive study and collecting of the lichens, many of the older trees have fallen, and the habitat has changed greatly. In 1914, Tobler noticed that the lichens were dying in considerable numbers, and he supposed that the light requirements might no longer be favorable for their growth on portions of the trunks within reach. But observation showed that the lichens did not flourish better higher up on the trees, the development ceasing rather abruptly at certain heights. He therefore decided to obtain data regarding possible effects of atmospheric moisture. Selecting an oak tree, he found that at 9 in the morning there was 4 per cent more moisture on the north side of the base of the tree than on the east or west sides. At the height of his head the difference was 3.5 per cent in favor of the north side over the west side and 2.5 per cent higher than on the east side. Another tree showed slightly greater difference at the height of his head, and the atmospheric moisture was, as a whole, about 10 per cent lower than about the 1st tree. Correlated with this difference in moisture he found that *Pertusaria amara* was growing but sparingly on the 1st tree at a height of about 0.5 m. above the ground and on the north side only, while on the 2nd tree this lichen grew from 0.5 to 2 m. from the ground on the north side and extended around somewhat to the east and west sides. He concluded that changes in atmospheric moisture, due to development of the forest and removal of undergrowth, working through the years since Lahm collected the lichens, had been the main deciding factor in the changes that have occurred in the lichen flora. Further, he found the temperature to be about 2°C. lower on the north side of the tree than on other sides, and this lower temperature would probably supplement the difference in atmospheric moisture.—*Bruce Fink.*

2312. TULLSON, H. **Prolonged plant activity at Grand Haven, Mich., in autumn of 1920.** *Monthly Weather Rev.* 49: 608-609. 1921.—Because of the mildness of the late fall and the occurrence of snow on the ground during periods of killing frosts and low temperatures, many plants blossomed profusely as late as Jan. 1, 1921, when with heavy frosts and ground free from snow all annuals which had been in a growing condition were killed.—*E. N. Munns.*

2313. VAN CLEEF, EUGENE. **Rainfall maps of Latin America.** *Monthly Weather Rev.* 49: 537-540. *Charts 150-152.* 1921.—The distribution of the annual, summer, and winter rainfall over South America is shown in a series of charts. The vegetation gives little clue as to the possible reasons for the rather semi-arid condition of the llanos of Colombia and Venezuela.—*E. N. Munns.*

STRUCTURE AND BEHAVIOR

2314. CHODAT, R., et L. CARISSO. **La vegetation du Paraguay. XI. Borriginacees. B. La myrmecophilie des Cordia de la section Gerascanthus.** *Bull. Soc. Bot. Genève* 12: 172-200. *Fig. 313-327.* 1920.—Certain species of "fire ants" are known to inhabit cavities in the stems of *Cordia*. No one formerly recognized these growths as true galls. By means of a series of stages of such growths from several species of *Cordia* it was possible to demonstrate the presence of ant larvae in all of the earliest stages and the growths resulting from the presence of the ants were typical galls.—*W. H. Emig.*

2315. CHRISTY, MILLER. **The flowering-times of some British elms.** *Jour. Bot.* 60: 36-41. 1922.—Notes on the flowering time of *Ulmus nitens* and *U. montana* were made for a period of several years. The date of the appearance of flowers of *U. nitens* varied from the beginning of January to the beginning of February but in exceptional years the flowers appeared as early as the end of December or as late as the end of March. There was considerable variation also in the numbers of flowers and, as a rule, the majority produced infertile seed. *U. montana* flowered with fair regularity from the middle to the end of March, rarely as late as the 1st week in April. Usually a large number of flowers appeared and the majority of them produced fertile seed.—*Adele Lewis Grant.*

2316. CLARK, J. EDMUND. **Flowering dates of trees along the main British railway routes.** *Nature* 109: 210-212. 1922.—Inquiry was made to establish an observation that in traveling from the west of England to London fruit trees are seen to be more precocious toward London. Phenological reports give no direct data since fruit trees and garden flowers were excluded from the list on account of the numerous varieties. Studies were made from data of black-thorn, garlic, hedge-mustard, horse chestnut, and hawthorn, 35 stations being available for 1920, but the season was abnormally early. It is concluded that London is at least a week earlier than Penzance. Further discussion is made of details and modifying influences. The Hopkins bioclimatic law appears to hold. Further confirmation was found in the study of a manuscript received from Prof. Hopkins. "The success obtained seems to imply that from absolutely trustworthy phenological records of seasonal changes for a single station in the northern hemisphere for one single plant, the whole seasonal phenology for any other plant or crop can be postulated for any other spot in North America, Europe, or Asia."—*O. A. Stevens.*

2317. DALLMAN, A. A. **The pollination of the primrose.** *Jour. Bot.* 59: 316-322, 337-345. 1921.—From systematic field observations carried on in North Wales and Sussex for a period of several years, the author concludes that certain Dipterous and Hymenopterous insects are active agents in the pollination of primroses. Snails and slugs and certain beetles assist during the night time but no moths were seen visiting the flowers. A number of hitherto unrecorded insect visitors to primroses are listed.—*Adele Lewis Grant.*

2318. LYON, C. J. **A phaenological study in New England.** *Torreyia* 22: 19-28. 1922.—The correlation between temperature and the time of first flowering was studied in the vicinity

of Hanover, New Hampshire, for the years 1917-1921 inclusive. A table showing the time of first flowering for 104 species is presented, indicating a wide range of variation definitely correlated with the temperature factor.—*J. C. Nelson.*

2319. PEMBERTON, C. C. Some notes of the growth of *Arbutus Menziesii* Pursh. Canadian Field Nat. 36: 21-26. Fig. 1-4. 1922.—On Vancouver Island there are large single trees of *Arbutus Menziesii* scattered on the plains, on margins of the forests, and on the sparsely wooded crests of hills and rocky elevations. Some trees give evidence of positive heliotropism. There was a continuity of flowering for 4 growing seasons. All stages from young buds to mature fruits occurred simultaneously.—*W. H. Emig.*

2320. PESSIN, LOUIS J. Epiphyllous plants of certain regions in Jamaica. Bull. Torrey Bot. Club 49: 1-14. Pl. 1, fig. 1. 1922.—A report is made of a study, in the field and laboratory, of epiphyllous plants in Jamaica. Possible modes of attaining the epiphyllous position are given as: continual growing forward and dying off below, of bryophytes, until they reach and cover the leaf; distribution, by rain and wind, of spores, etc.; and propagation of lichens and bryophytes by displaced fragments. Abundance of humidity, moderate temperature and calm atmosphere encourage epiphyllous growth. No penetration of the leaf by the epiphyll could be detected. Epiphyllous hepatics have specially adapted rhizoids. There is a possible relation between epiphyllous modes of life and parasitism.—*P. A. Munz.*

2321. PLITT, CHARLES C. A preliminary report, with notes, on the lichens found near the Cinchona Botanical Station, Jamaica, British West Indies. Bryologist 24: 60-64. 1921.—The author collected about 200 species of lichens near Cinchona in the summer of 1919. The actual enumeration of species is left for a subsequent article. The present paper outlines the physical and climatic conditions of the locality, and notes the habital and ecological relationships of the lichens found. For this purpose the species are roughly classified as fruticose, foliose, and crustose forms, only the first set being included in the present instalment.—Some tests of water absorption showed that air-dried material of *Cladonia aggregata* exposed to rain would take up 110 per cent of its weight of water, *C. pycnoclada*, 200, *Sticta aurata*, 300, and *Leptogonium bullatum*, 400 per cent. [See also following entry.]—*E. B. Chamberlain.*

2322. PLITT, CHARLES C. A preliminary report, with notes, on the lichens found near the Cinchona Botanical Station, Jamaica, British West Indies. Bryologist 24: 70-74. 1921.—This concluding part of the report deals with foliose, crustose, and epiphyllous lichens. It is, in the main, a running account of collections and ecological notes. The author concludes that *Sticta* and *Leptogonium* seem best able among the foliose lichens to endure shade, often extending horizontally outward and spirally around tree trunks to utilize the light. [See also preceding entry.]—*E. B. Chamberlain.*

2323. THOMPSON, H. STUART. The mild weather. Nature 106: 728. 1921.—*Hutchinsia petraea* was found in blossom Jan. 24 near Bristol. The usual period is from Mar. to Apr. The hazel was in full flower on Jan. 5.—*O. A. Stevens.*

VEGETATION

2324. ADAMSON, R. S. Studies of the vegetation of the English chalk, I. The woodlands of Ditcham Park, Hampshire. Jour. Ecol. 9: 113-219. 6 p., 13 fig. 1922.—This includes a detailed study of 4 types of woodland, namely, beech and oak-hazel forests and 2 sorts of coppice. The data concerning the habitats include mechanical and chemical analyses of the soils including H-ion determinations, light intensities measured by actinic paper, evaporation determinations by the Yapp atmometer, humidity, rainfall, and temperature data from meteorological records. Extensive plant lists give an analysis of the flora. On the chalk soils 2 types of forests dominated by *Fagus silvatica* are described. On west-facing slopes such woods have few shrubs and a sparse ground flora in which *Sanicula europaea* and *Epilobium angustifolium* are most abundant, the former in the deep shade and the latter where more light pene-

trates. On the north-facing slopes *Mercurialis perennis* forms much of the ground flora. On the plateau more grasses and mosses occur under the beeches. In the "calicicolous coppice" *Cornus* and *Fraxinus* are most abundant while in a "transition coppice" *Corylus*, *Fraxinus*, and *Betula* are dominant. These coppices are related to the different types of beech forest.—An oak-hazel forest is developed on some of the deeper leached soils. *Quercus robur* is here the chief tree but *Betula alba* and *Fraxinus excelsior* are usually present in considerable numbers. The chief shrub is *Corylus avellana* with *Cornus sanguinea* and *Euonymus europaeus* rather abundant. The undergrowth shows several variations but *Mercurialis perennis* is generally abundant.—*Geo. D. Fuller.*

2325. CHODAT, R., et G. BEAUVERD. Herborisation du 17 juin aux Buxaies de la Sarraz (Vaud). Bull. Soc. Bot. Genève 12: 142-148. 1920.—The spring flora near Sarraz is divided into a number of ecological groups.—*W. H. Emig.*

2326. DICE, L. R. Biotic areas and ecologic habitats as units for the statements of animal and plant distribution. Science 55: 335-338. 1922.

2327. HANDEL-MAZZETTI, HEINR. Übersicht über die wichtigsten Vegetationsstufen und -formationen von Yünnan und SW.-Setschuan. [Survey of the principal vegetation zones and formations of Yunnan and southwest Szechuan.] Bot. Jahrb. 56: 578-597. 1921.—This is an elaboration of a paper first published in 1916 [Sitzungsber. Akad. Wiss. Wien (Math.-Naturwiss. Kl.) July 1916, Nov. 1917, and Jan. 1920] and is based on the vertical distribution of about 400 indicator plants. The author discusses his conclusions in comparison with those of Wilson. Because of complications due to the deep narrow valleys in the mountains it was necessary to treat this area separately from the Yunnan tableland. The subject matter is treated under the following headings: A. Tropical province. (1) Tropical rainforest: (2) tropical savanna; (3) jungle; (4) sclerophyllous bush; (5) subtropical savanna forest; (6) water plants. *Musa sapientum* and *Carica papaya* are characteristic cultivated plants.—B. Region of Yunnan tableland. (1) Subtropical zone (about 1800 m.), dry in summer, temperature 18-30°C. in summer; (a) subtropical savanna forest, (a¹) lower part with succulents, *Citrus*, and *Saccharum*, divided into southern zone and northern zone, (a²) upper part, without succulents; (b) grass steppes; (c) ravine forest; (d) rock desert; (e) sand steppes. (2) Warm temperature zone, 1800-2900 m., of which 9 associations are recognized and described.—C. Region of high mountains of North Yunnan and southwest Szechuan including 6 zones as follows: subtropical, warm temperate, temperate, cold temperate, high mountains, and snow zones, with extensive subdivisions under each.—D. Northeast Birma- and West Yunnan high mountains, divided also according to climate into subtropical, warm temperate, temperate, cold temperate, high mountains, and snow regions with extensive subdivisions.—*K. M. Wiegand.*

2328. HASTINGS, G. T. Succession of algae in the Grassy Sprain reservoir. Jour. New York Bot. Gard. 22: 64-66. 1921.—In this artificial reservoir near New York City there is a succession of algae throughout the season. The green algae reach their maximum in late May and early June, and the blue-greens in September.—*H. A. Gleason.*

2329. HOWE, MARSHALL A. The "working" of Long Lake. Jour. New York Bot. Gard. 22: 156-159. 1921.—The "working" of this lake at the New York Botanical Garden was caused by the prolific development of *Oscillatoria prolifica* (Grev.) Gomont.—*H. A. Gleason.*

2330. KENOYER, L. A. Forest formations and successions of the Sat Tal Valley, Kumaon Himalayas. Jour. Indian Bot. 2: 236-258. 6 pl., 3 fig. 1921.—Sat Tal Valley lies just north of the outermost range of the Himalayas, at 29° 23' N. Lat., 79° 32' E. Long. Altitudes vary from 4160 to 5860 feet. At this elevation the 3 great forest formations of the lower Himalayas—monsoon deciduous, broad leaf sclerophyll, and *Pinus longifolia*—meet. Frost may occur down to 4000 feet. The annual rainfall is 85 inches, of which 84 per cent falls during June—

Sept. The monsoon deciduous forest, ranging from 2500 to 5500 feet, is dominated by *Bauhinia variegata*, *B. retusa*, and the giant liana *B. VahlII*; other common trees are *Terminalia* spp., and *Grewia asiatica*. This forest reaches its upper limit in the Sat Tal Valley, where it is confined to southerly exposures. It is determined by a periodic precipitation, and a temperature that seldom falls below freezing. Most of the trees are deciduous; leaf fall with some species begins in the winter, and during March–May most of the species are bare. A large number flower at this time. Leaf fall appears to be due to moisture deficiency; but it is surprising that most of the deciduous species put out new leaves before the monsoon has begun. Commonly the new leaves do not appear till the fruits are mature; young trees and staminate trees were observed to leaf out much sooner than fruit-bearing trees. The broad leaf sclerophyll formation in the Himalayas falls into 3 altitudinal zones, each dominated by a distinct species of *Quercus*. Only the lowest of these zones, extending from the monsoon deciduous forest to 8000 feet, and dominated by *Q. incana*, occurs at Sat Tal. With this oak are *Rhododendron arboreum* and *Pieris ovalifolia*. This forest reaches its lower limits in the Sat Tal Valley, and is confined to cooler, shadier northerly exposures, and to moist depressions. It requires a winter temperature falling somewhat below freezing, and greater humidity than the monsoon deciduous forest. None of the dominant trees are ever quite leafless. The *Pinus longifolia* forest contains no other important species; it attains greatest development between 4000 and 6500 feet, and is always confined to dry exposed ridges and hilltops. In the Sat Tal Valley the monsoon deciduous forest occupies the warmer south-facing slopes and valleys, the *Quercus incana* forest the cooler north-facing slopes and valleys, while the *Pinus longifolia* is found on the dry ridges between them. The author attempts to work out both hydrarch and xerarch successions, though the valley has been protected from grazing, cutting, and fire for only a few years. He concludes that “the pine and the *Bauhinia* seem to be xerarch pioneers” in this area, “and the oak is the climax toward which the former two tend.” Seasonal periodicity is a marked feature of the vegetation. During the monsoon, June–Sept., the herbaceous vegetation shows decided tropical affinities, while in the autumn and spring the under-vegetation is more like that of temperate regions. Lianas and parasites are rather abundant. Epiphytic lichens, mosses, and ferns are abundant in the oak forest, and orchids are common in the monsoon deciduous forest. A list is appended of about 75 tree and 65 shrub species observed by the author.—*Winfield Dudgeon*.

2331. MALTA, N. Ökologische und floristische Studien über Granitblockmoose in Lettland. [Ecologic and floristic studies of the mosses on granite erratics in Livonia.] *Latvijas Augstskolas Raksti* (Acta Universitatis Latviensis) 1: 108–124. 1921.—Floristically, granitic erratics in the lowlands are interesting from the presence of montane species far below the usual levels; ecologically, the erratics, through restricted area and constant character of the substratum, permit easy determination of the effect of varying conditions of atmosphere and insolation, and facilitate the study of the impact of different plant associations. The thinnest layers of soil over a granitic erratic change the moss flora profoundly, often with sharp contrasts between top and sides of the block, while a limestone block will make its influence felt through the accumulated material. Hence a granite block may show rapid change in its flora in the course of years, at times becoming wholly submerged by inroads of surrounding associations. This submergence is conditioned by the size of the block, presence of moisture, insolation, slope of the sides, and the relative vigor of surrounding associations. Per contra, large blocks in sunny places show great fixity in their moss flora even over long periods, though the surrounding terrain is undergoing constant change through cultivation, if only mechanical injury from men or animals is absent. The changes in moisture, as through drainage of swamps, seem to produce the most rapid changes in flora.—The colonization of new plants on bare blocks seems dependent upon the relief of the surface and hence upon the petrologic composition. Smooth surfaces seem first occupied by lichens between which mosses later appear; rough surfaces support a large flora in the minute hollows, as many as 27 plants (13 species) to the square m. being noted.—Four moss associations may be recognized, 3 conditioned by sunlight (the *Grimmia*-association of full sunlight, the shady-thicket-association, the woodland-association), and 1 (the hydrophyte-association) by water content. Lists of species

characteristic of each association are given, and a general list of 15 hepatics and 96 mosses considered as true granite dwellers. A bibliography of 10 titles follows.—*E. B. Chamberlain.*

2332. O'DONOGHUE, CHAS. H. A preliminary survey of the biota of a sand spit in Lake Winnipeg. *Canadian Field Nat.* 35: 121-131. 1921.—This sketch of the life conditions on a sand spit of Berens Island includes a list of plants arranged according to zones and frequency.—*W. H. Emig.*

2333. PEASE, A. S. Gray pine and arbor vitae. *Rhodora* 23: 247-249. 1921.—Observations were made from the car window upon the growth of *Pinus Banksiana* and *Thuja occidentalis* along the line of the Algoma Central and Hudson Bay Railroad from Salt Ste. Marie, Ontario, northward for nearly 300 miles, and extended eastward along the line of the National Transcontinental Railway toward Quebec. In general, the 2 species were not seen in the same regions and where their ranges overlapped there was evidence of a decided difference in their habitats, to this extent corroborating the conclusions of Fernald in respect to these 2 species [see *Bot. Absts.* 4, Entry 283.].—*James P. Poole.*

2334. POISSON, H. La flore septentrionale de Madagascar et la flore malgache. [The northern flora of Madagascar and the Madagascan flora.] *Rev. Gen. Bot.* 33: 577-588, 694-707, 758-770. 1921.—The flora is influenced by 3 factors—soil, climate, and man. Of the 3, man has caused most change. Three regions are considered from a geological and geographical point of view,—the central part, and the western, and eastern coasts of Madagascar.—The Madagascan flora is becoming uniform due to the extension of the savannas; it will return to regional characteristics very slowly because the soil will be recovered by cultivated plants. From the point of view of the botanist this loss of rare and curious species is to be regretted, but the development of agriculture is for the greater good of Madagascar. It would be better to cut the brush than to burn it for then in the places inaccessible for cultivation many interesting forms would be found among the remaining species.—The flora is divided into 4 groups based on the types of soil on which they grow. These groups are: (1) the limestone flora, presenting a majority of xerophytes; (2) the sand and sandstone flora; (3) the savanna flora, chiefly Gramineae; and (4) the tropical forest flora. Lists of the plants found in these localities are given.—*J. C. Gilman.*

2335. PONCY, R. Contribution a la biologie des tourbieres Genevoises. [Contributions to the biology of the Swiss bogs.] *Bull. Soc. Bot. Genève* 12: 150. 1920.—This paper includes observations of *Iris pseudacorus* L. and *Nymphaea alba* of the Swiss bogs.—*W. H. Emig.*

2336. UPHOF, J. C. TH. Ecological relations of plants in southeastern Missouri. *Amer. Jour. Bot.* 9: 1-17. 2 pl., 3 fig. 1922.—The author describes the geology, topography, and climate of this region. There are 2 main ecological areas, the Ozark Hills and the bottom lands along the rivers. He describes the plant associations and lists the important species of the dry barren hills and of the richer lower slopes in the Ozarks, and of the ponds, swamps, and forests of the bottom lands.—*E. W. Sinnott.*

2337. WILSON, E. H. Notes from Australasia. II. The New Zealand forests. *Jour. Arnold Arboretum* 2: 232-236. 1921 [1922].—New Zealand, before its settlement by white men, was for the most part densely clothed with a mixed rain forest in which old types of taxads and conifers were the dominant trees; of these the most valuable timber trees are *Dacrydium cupressinum* Sol., 4 species of *Podocarpus*, and *Agathis australis* Steud., the Kauri, the tallest of the New Zealand trees, attaining a height of 150 feet. These trees have the roots clothed with tubercles analogous to those of leguminous plants which contain nitrogen-fixing bacteria. This explains the slow and poor regeneration of these trees on the deforested areas where the soil has become unfit for their growth, on account of the destruction of the bacteria by exposure and fire. Ruthless destruction during the last century has reduced the forested area greatly,

and as the regeneration of the taxads and conifers is difficult in the dense forest because of the shade, and on the deforested areas for the reason stated above, the broadleaf dicotyledonous trees, which are of less commercial importance, will supersede these older types.—*Alfred Rehder.*

FLORISTIC PLANT GEOGRAPHY

2338. BEWS, J. W. The south-east African flora: its origin, migrations and evolutionary tendencies. *Ann. Botany* 36: 209-224. 1922.—The flora of Southeast Africa is composed of 2 distinct elements, a tropical-subtropical one and a temperate one. The tropical flora has invaded the region along the coast-belt, where it remains distinctly tropical. Toward the south the tropical species are gradually replaced by allied subtropical forms. Migration has also occurred toward the interior from the coast-belt along the river valleys which run at right angles to the coast. In this direction also the flora soon becomes subtropical in association with the higher altitude, lower temperature, and drier conditions. When allied tropical and subtropical forms are compared in respect to floral morphology it is generally found that the former are more primitive. It is concluded that the subtropical forms are derived from the tropical element in adaptation to the changed conditions. The temperate element has migrated along the great mountain ranges which run parallel to the eastern coast across the tropics and connect with the southwestern Cape region. When allied tropical and temperate forms are compared in regard to floral morphology, it is found that in many families the tropical element is the older while in others the temperate representatives have retained more of the primitive floral characters. Particular examples are given of tropical genera (e.g., *Rhus*) which have produced species that have invaded temperate regions and also of temperate genera (e.g., *Pelargonium*) which have invaded the tropics.—*W. P. Thompson.*

2339. HARPER, ROLAND M. Cape Cod vegetation. *Torreyia* 21: 91-98. 2 fig. 1921.—A bibliography of the various papers dealing with the flora of the Cape is presented. None of these describes the vegetation in detail. In surface features and plant topography the Cape resembles Long Island. Though formerly destitute of trees, there is now considerable forest. The author spent 3 days in October, 1920, studying the vegetation. Lists are presented of the plants observed, including 16 trees, 4 woody vines, 16 shrubs, 4 undershrubs, and 20 herbs. Ten of the entire list are thought to be introduced. *Pinus rigida* is the most abundant tree. Nearly all of these plants grow also on Long Island. Many species common in the interior of New England are absent.—*J. C. Nelson.*

2340. NELSON, EDWARD W. Lower California and its natural resources. *Mem. Nat. Acad. Sci. [U. S. A.]* 16: 1-194. 1921.—In this treatment of the Peninsula of Lower California the following sections are of especial botanical interest: Plant Life, p. 103-110; Life Zones, p. 121-132; Natural Resources in Animal and Plant Life, p. 132-136; Scientific Explorations, p. 140-147; Bibliography of Lower California, p. 147-171. The author considers that the vegetation of the Peninsula has been derived from 3 sources. The northwestern portion, consisting chiefly of the San Pedro Martir Mountains, bears a flora that is identical with that of the mountains of southern California. The southern third shows a strong infusion of species from the arid tropical lowlands and low mountains of Sinaloa. The remaining two thirds shows a close connection with desert regions of southwestern U. S. A. and northwestern Mexico. The flora of the Peninsula is characterized as being one of the most remarkable desert floras in the world.—*Rozana Stinchfield Ferris.*

2341. PALMER, ERNEST J. The forest flora of the Ozark region. *Jour. Arnold Arboretum* 2: 216-232. 1921 [1922].—The author gives a brief account of the topography, geology, and climate of the Ozark region bounded on the east and north by the valleys of the Mississippi and Missouri rivers, on the south by the Gulf Coastal Plain, and on the west by the Great Plains. It is one of the oldest land areas of the continent and consists chiefly of older palaeozoic sedimentaries. The annual rainfall through almost the entire Ozark region averages between 35 and 40 inches. The composition of the forest flora and its different formations are de-

scribed and it is stated that about 90 per cent of the woody plants belong to the Gulf Coastal Plain flora. Numerous colonies of northeastern woody plants together with many herbaceous species are found on the northern and eastern slopes of bluffs and steep hillsides. It is stated that the movement of the southern flora toward the north is of comparatively recent inception and still in active progress, the less hardy species gradually disappearing toward the north; the forest is encroaching upon the prairies of the northwestern portion and upon the treeless hills characteristic for some sections of the western part of the region and is driving back the remnants of the flora of the western plains which still exist in these parts.—*Alfred Rehder.*

2342. WILLIAMS, M. Y. **Biological notes along fourteen hundred miles of the Mackenzie River system.** Canadian Field Nat. 36: 61-66. 1922.—Besides observations on the fauna of the region, there is a short list of flowering plants and a few notes on the ecological associations.—*W. H. Emig.*

APPLIED ECOLOGY

2343. ANONYMOUS. **Searching the world for new food plants.** Sci. Amer. Monthly 3: 516-518. 6 fig. 1921.—A brief account is presented of the expedition of H. L. SHANTZ and REVAL through darkest Africa in quest of new fruits, nut plants, and forage crops.—*Chas. H. Otis.*

2344. DIEHL, G. B. **Relation between the rainfall, temperature and the yield of corn in Argentina.** Monthly Weather Rev. 49: 543-548. Fig. 1-6. 1921. [Translation of: HESSLING, N. A. *Relaciones entre la lluvia, la temperatura y el rendimiento del maiz.* Bol. Mens. Oficina Meteorol. Nacion. Oct., 1918.]—The relation between yields and climate for corn has been found to be the precipitation during the Oct.-Jan. period with temperature a minor factor. In the calculations, the coefficient of correlation was used.—*E. N. Munns.*

2345. SLADEN, F. W. L. **Fireweed as a honey-plant.** Agric. Jour. [British Columbia] 6: 122. 1921.—The status of this plant as a honey producer is discussed with some reference to local conditions.—*J. W. Eastham.*

2346. WEST, FRANK L., and N. E. EDLEFSEN. **The climate of Utah.** Utah Agric. Exp. Sta. Bull. 166. 66 p., 18 fig. 1919.—This is a summary of the climatic conditions of Utah, based upon a careful study of weather data taken at the leading town of each county in the state. The amount and distribution of rainfall and the length of the growing season are shown in graphic form for each county.—*B. L. Richards.*

FOREST BOTANY AND FORESTRY

J. S. ILLICK, *Editor*

(See also in this issue Entries 2229, 2269, 2324, 2330, 2510, 2689)

2350. ANONYMOUS. **Annual return of statistics relating to forest administration in British India for the year 1919-20.** 25 p. Simla, 1921.—Summaries are presented for British

India forest work, and among the important subjects discussed are working plans, forest offenses, fire protection, grazing, planting, forest utilization, forest income, and forest area.—*S. B. Show.*

2351. ANONYMOUS. *Les lignes électriques à travers les forêts.* (Conférence de M. W. von ARX, inspecteur des forêts de la ville de Soleure, à la réunion de la Société Forestière Suisse à Aarau, le 29 août 1921.) [*The electrical lines across the forests.*] Jour. Forest. Suisse 73: 6-10. 1922.—It is proposed to check by proper legislation the unscrupulous expansion of transmission systems by electro-technic interests, which are ignoring entirely forestry and esthetic considerations. It is desirable to eliminate shortcomings of existing laws, which differentiate between public and private utilities companies.—*G. Kempff.*

2352. ANONYMOUS. *Progress report of forest research work in India for the forest year 1919-20, including the administration report of the Forest Research Institute, Dehra Dun.* 56 p. Allahabad, 1920.—This is the 1st general summary of the research work of the Indian Forest Service, and covers all phases of the work, both that done at and under the direction of the Central Institute at Dehra Dun and the work in the various provinces. One chapter each is devoted to silviculture and working plans, forest botany, forest economy, forest zoology, forest chemistry, as the major subdivisions of research work, and 1 each to a general survey of the situation and to forest publications. A total of 294 permanent sample plots are now under observation by the Central Institute, in addition to others carried by the provincial offices. The experiments in regeneration are largely devoted to study of sal. Experimental work in regeneration of the evergreen forests of Eastern Assam have been initiated. In Burma extensive work with teak regeneration has been undertaken. In Madras regeneration of the deciduous semi-evergreen forests is being studied. The diseases of sal dominate as the principal studies under forest botany. Studies in forest economy are being started extensively. Pulp and paper, antiseptic treatment, seasoning, mechanical properties, by-products, veneers, cooperage, new uses and technical qualities are all being studied. Insects affecting sal and teak especially are studied. The gums, resins, camphor, turpentine and tannins from oaks are also being investigated.—This publication is designed primarily to give workers in India a complete picture of the experiments under way, but will be welcomed by those in other countries who have heretofore been obliged to look through numerous special provincial reports to secure the information here brought under one cover.—*S. B. Show.*

2353. ANONYMOUS. *The progress of state afforestation.* [Rev. of: ANONYMOUS. *Second report of the forestry commissioners: Year ending Sept. 30, 1921.* H. M. Stationery Office: London, 1922.] Nature 110: 369-370. 1922.—On account of reduced appropriations a leasing policy was pursued. The commission secured over 68,000 acres of which nearly 8,000 were planted. Small grants to land owners secured the planting of 11,000 acres on private estates. Afforestation provides work for the unemployed. Material assistance was received from the Unemployment Fund. Four schools for apprentice woodmen were established, and experimental work is in progress on 79 sample plots.—*O. A. Stevens.*

2354. ANONYMOUS. *Forest policy and forest management.* [Rev. of: (1) SCHLICH, W. *Schlich's manual of forestry.* Vol. I. *Forest policy in the British Empire.* 4th ed., rev. and enlarged, xi + 342 p. Bradbury, Agnew and Co.: London, 1922. (2) HAWLEY, R. C. *The practice of silviculture; with particular reference to its application in the United States.* xi + 352 p. J. Absts. 12, Entry 398]. (4) JACKSON, H. *A short manual of forest management.* x + 70 p. University Press: Cambridge, 1921.] Nature 110: 407-409. 1922.

2355. AFZAL, MUHAMMED. *Progress report of forest administration in Baluchistan for 1919-20.* iii + 25 p. Calcutta, 1921.—Chil (*Pinus longifolia*) seedlings which were watered during the summer have done well, while those untended have died. In general the problem

is to protect and develop the forests of this province, which is much behind most of the other provinces of India. The usual detailed tabulations of area, offenses, fires, output, receipts, expenditures, etc., are given.—*S. B. Show.*

2356. AFZAL, MUHAMMED. Progress report of forest administration in Baluchistan for 1920-21. *iii* + 24 p. Calcutta, 1922.—The usual detailed tabulations of area, offenses, output, receipts, expenditures, etc., are given. The forests of the Zhob district are administered by the political agent and are reported on separately.—*S. B. Show.*

2357. ALTSON, A. M. Beetles damaging seasoned timber: With an account of their ravages and the method of treatment. *Roy.* 8 vo, 24 p. Wm. Rider & Sons: London, 1922. 2s. 6d. net.

2358. BADOUX, H. Quelques observations sur les dégât causés récemment par la pyrale grise du mélèze. [Some observations of recent devastations by the gray larch caterpillar.] *Jour. Forest. Suisse* 73: 1-6. 1 pl. 1922.—The gray larch caterpillar (*Steganoptycha pini-colana*) defoliates larch stands (*Larix europaea*) by devouring the needles. Its life cycle and habits are briefly described. All the damage is caused during the larval stage, in 23-28 days during May and June, and consists essentially of a loss of growth. The infestations occur at regular intervals of about 9 years, each invasion lasting 2-3 years. The danger of infestation to larch stands may be lessened by appropriate preventive measures, such as thinnings, mixed stands, etc.; but all repressive measures tried have proved unsuccessful.—Observations made during the summer of 1921 show extensive infestations and depredations not only in larch but also in Cembran and mountain pine. The attack occurred exclusively upon the current annual shoots, principally the leader, resulting in a considerable loss of growth.—*G. Kempff.*

2359. BARBEY, A. La Nonne dans les Alpes valaisannes. [The gypsy moth in the Valaisian Alps.] *Jour. Forest. Suisse* 73: 21-25. 1 pl. 1922.—The author describes the first known moth invasion of the Swiss forests, which occurred during the dry summer of 1921. An unidentified moth attacked a stand 1 hectare in size, located in the communal forest of Ernen just above the junction of the Binna and the Rhone rivers and composed of 90 per cent *Præa excelsa* and 10 per cent *Pinus sylvestris* 60-80 years old. The observations on the habits of the insects and the resultant damage are reviewed, as well as the possible cause of the invasion. The utilization of all infested material and the complete burning of all the bark are the chief repressive measures put into effect.—*G. Kempff.*

2360. BENNETT, H. C. Progress report of forest administration in Coorg for 1920-21, with a review by the chief commissioner and orders by the government of India. 2 + 16 + 14 p. Bangalore, 1922.—As for the other divisions of India, the report for this year covers only a 9-month's period in order that the forest and fiscal years may be made to coincide. Among the important subjects discussed are reforestation, reproduction methods, eradication of lantana from sandal-bearing areas, care of plantation and teak taungyas, forest fires, protection, diseases, felling operations, forest products, market conditions, revenues, and expenditures. Research on the spike disease of sandal continued, though with inconclusive results, and a wide variety of other silvicultural problems are also being studied intensively. Protection-burning of grass hills was done with help from villages and with satisfactory results, no accidental fires being reported. The customary detailed tabulations of various phases of the department's work are included in the report.—*S. B. Show.*

2361. BILLSON, H. G. Annual progress report of forest administration in the United Provinces for the forest year 1919-20. 34 + lxxxv + 5 p. Allahabad, 1920.—Forest area, working plans, road and trail construction, utilization operations, grazing, reforestation, timber sales, and forest incomes are among the important subjects considered. A summary of the report prepared by the Secretary to Government is included.—*S. B. Show.*

2362. BILLSON, H. G. *Annual progress report of forest administration in the United Provinces for the period July 1, 1920 to Mar. 31, 1921.* 28 + lxxiii + 3 p. Allahabad, 1921.—This is a detailed report of the activities of the Forest Department, but is for 9 months only, so that the forest year may be made to coincide with the fiscal year. It considers fully the subjects of forest area, road and trail construction, forest improvements, offenses, grazing, reforestation methods, felling operations, and forest income. Insect inquiry to sal continues serious. Poor and good natural reproduction are reported respectively for sal and chir pine forests. Resin output doubled in the year. A summary of the report by the Secretary to Government is included.—*S. B. Show.*

2363. BLASCHECK, A. D. *Progress report on forest administration in the Punjab for the year 1919-20.* 16 + lxxiii y., map. Lahore, 1920.—The report considers forest area, boundary surveys, working plans, forest offenses, fire protection, improvement and thinning work, cutting operations, forest income, and research. Late frosts damaged irrigated plantations.—*S. B. Show.*

2364. BLUNT, A. W. *Progress report of forest administration in the Province of Assam for the year 1919-20.* iii + 30 + 49 p. Shillong, 1920.—This annual report covers all phases of the work of the department, including statistics on area, boundary surveys, output, receipts, expenditures, offenses, fires, grazing, etc. Progress was made in reserving village forests, which is an urgent problem. In the reserved forests only 933 square miles were open to grazing whereas all unclassed forests were open. The eradication of climbers from sal forests is in arrears, though 2,300 acres were treated; burning was resorted to in order to rid the ground of evergreens. Natural reproduction of sal and teak was poor, but was good in the evergreen forests of the east. Experiments in natural regeneration of the evergreen forests, which are to be clear cut, promise success. No tapping was done on the Ficus plantations because of the lack of a market. Extending the taungya plantations of sal met with only moderate success. Improvement fellings in the sal forests of the west covered 9,338 acres; in the evergreen forests of the east, clear felling is to be practiced. A fair amount of research work on sal and the regeneration of the eastern evergreen forests is under way. A general summary of the important features of the report of the Secretary to Government is a valuable feature of the report.—*S. B. Show.*

2365. BRUBAKER, H. W. *A study of the oil from sumac (Rhus glabra).* Trans. Kansas Acad. Sci. 30: 221-222. 1919/21 [1922].—The chemical properties of the oil from berries of *Rhus glabra* are compared with those of other vegetable oils such as cotton seed and corn oil. A use may be found for it as an edible oil, in soap making, or as a semi-drying oil in the paint industry.—*F. C. Gates.*

2366. BUB-BODMAR, F., und B. TILGER. *Die Konservierung des Holzes in Theorie und Praxis: Ein Handbuch.* [Handbook on the theory and practice of wood preservation.] 8 vo, xx + 1006 p. P. Parey: Berlin, 1922.

2367. CARY, N. LEROY. *Sitka spruce; its uses, growth, and management.* U. S. Dept. Agric. Bull. 1060. 36 p., 20 pl. 1922.—This bulletin is a survey of the Sitka spruce industry on the Pacific coast from Alaska to northern California. The geographical and altitudinal distribution is given, with estimates of the amounts available. The character of the wood, its uses, and methods of logging and milling are described, together with the reproduction, growth and management.—*J. Lincoln Cartledge.*

2368. COULON, P. DE. *Jardinage cultural ou méthode du contrôle.* [Practical or mathematical application of the single tree method.] [Rev. of: BLOLEY, H. E. *L'aménagement des forêts par la méthode expérimentale et spécialement la méthode du contrôle.* (Forest management by the experimental method, especially the method of control.) 91 p. Attinger Frères: Paris, 1920.] Jour. Forest. Suisse 73: 25-29. 1922.—Biolley champions the mathe-

matical fixation of the cut in the working plan and its rigid application in the field. DeCoulon maintains that this is not feasible and should be omitted.—*G. Kempff.*

2369. COVENTRY, B. O. **Progress report of forest administration in the Jammu and Kashmir states for the year 1919-20.** (Sambat 1976.) 25 + lxiii p. Lahore, 1922.—This is an annual report on the work of the Forest Department. The area of state forests increased from 9639 to 9714 square miles. Among the important subjects discussed are boundary surveys, working plans, road construction, offenses, fires, reforestation, felling operations, rafting, forest products, forest income, and forest expenditures. Natural regeneration, especially in deodar forests, is good. Elimination of the destructive grazing by goats through gradual increase in fee is now under way. A force of 200 of the military was employed to suppress the smuggling of kuth out of the state. The Srinagar fuel supply continues to be a problem, with planting of willow on swamp land as the only solution. As in other states of India, plans are under way for increasing the staff. The usual detailed tabulations covering all phases of forest work are included in the report.—*S. B. Show.*

2370. COX, S. **Annual administration report of the forest department of the Madras Presidency (India) for the year ending June 30, 1919.** 87 + lxi + 11 p. Madras, 1920.—This annual report covers in detail all forest operations. The control of the Department was transferred from the Board of Revenue to the newly appointed Chief Conservator. The area of reserved forest decreased from 18,837 to 18,712 square miles, while reserved lands rose from 668 to 682 square miles. Forest working plans, offenses, fire losses, protection, grazing research, forest utilization, and forest income are considered. Bamboo and sandal-wood were extensively exploited. The Madras Forest College has continued satisfactorily. A separate report is given for each of the 4 circles in the Presidency, with a general summary, a statement of progress in each line of work for the 5-year period, and detailed statements of receipts, expenditures, fire protection, grazing, etc., for the different circles and subdivisions thereof.—*S. B. Show.*

2371. COX, S. **Annual administration report of the forest department of the Madras Presidency (India) for the three-fourths year ending March 31, 1921.** 83 + lxi + 11 p. Madras, 1921.—Since this report, covering in detail all forest operations, is for $\frac{3}{4}$ of the fiscal, instead of forest, year, the comparison with figures for previous years is impossible. It considers the subjects of forest area, boundary surveys, working plans, road construction, protection, offenses, grazing, utilization, and forest income. Protection burning was inaugurated. The possibilities of bamboo as a source of paper pulp are discussed. Important progress in the artificial regeneration of teak is noted. In the review of the report by the Government, the need for education of the people in the aims of the forest administration is emphasized. The forest college continued to work well. A separate report for each of the circles is given with a general summary for the entire Presidency, a review by the Government, and detailed statements of receipts, expenditures, fire protection, grazing, changes in area, etc., for the different circles and subdivisions thereof.—*S. B. Show.*

2372. CROTHERS, E. M. **Progress report of forest administration in Coorg for 1919-1920, with a review by the Chief Commissioner and orders by the Government of India.** 2 + 13 + 14 p. Bangalore, 1921.—This is an annual report on all phases of forest administration. The area of reserved forests remained constant at 332,500 acres. Among the important subjects discussed are forest improvements, fire protection, grazing, planting, felling operations, forest income, and expenditures. Studies on the relation of lantana to sandal disease were continued as well as efforts to eradicate the pest on plantation and regeneration areas. Sowing of teak and cultural operations on previous plantations were continued. Considerable research work covering a wide range of subjects is being done: sample plots for growth and yield studies, attempts to produce artificially the "spike" disease of sandal, studies on soil aeration, natural reproduction, thinnings in teak, sowing and planting are all represented. The usual detailed tabulations covering areas, progress in various phases of the work, output, receipts, etc., are included.—*S. B. Show.*

2373. DONS, CARL. Litt om store traer i Nord-Norge. [A little about big trees in northern Norway.] *Naturen* 46: 220-236. *Fig. 1-12*. 1922.

2374. GERRY, ELOISE. Oleoresin production: A microscopic study of the effects produced on the woody tissues of southern pines by different methods of turpentine. U. S. Dept. Agric. Bull. 1064. 46 p., 7 pl. 1922.—Results clearly demonstrate that those methods of turpentine which conserve the vitality of the tree insure the greatest production of oleoresin. "Turpentine is not merely a draining out of the gum already formed; it is a collection of the oleoresin constantly being manufactured by the tree." Production is greatly increased due to wounding. Cupping in place of boxing eliminates unnecessary injury to the tree and the proper spacing and placing of the faces on the tree are matters of fundamental importance. It is unprofitable to turpentine trees less than 10 inches in diameter by present commercial methods. Turpentine does not effect the wood already formed, except the living parenchyma in the outer sapwood, the resin passages which contribute much of the yield. Structure of the wood produced after wounding is considerably modified especially above the face, where many more resin passages are formed. This is greatest about 1 foot above the wound and still slight at 6-9 feet above. Although the increase in resin passages is an important factor in securing a high yield, they are not the only, or perhaps not even the chief, source of the turpentine. Differences in chipping methods effect structure of the wood and production. Heavy chipping is much more injurious to the tree and gives lower sustained yield than conservative narrow chipping. The former results in delay in wood formation, in formation of resiniferous tissue, in a reduction in the width of annual rings, and in thickness and amount of walls of the summer wood, while conservative narrow chipping largely overcomes these disadvantages. Wood formation, especially the width of the growth rings and the amount of summer wood produced by uninterrupted trees of the same locality, was taken as the standard for estimating the effects of the different chipping methods. Many miscellaneous observations and suggestions of further problems are added.—*J. T. Buchholz*.

2375. GRIEVE, J. W. A. Progress report on forest administration in the Punjab for the year 1920-21. 19 + *lviii* p., *map*. Lahore, 1921.—The report covers only a 9-month's period, since, as in other provinces, the forest year and fiscal year are being made to coincide. The area controlled by the Department was reduced from 6744 to 6626 square miles chiefly by devoting lands to colonization. This is only 7 per cent of the total area of the Punjab. Among the important subjects discussed are working plans, labor problems, transportation facilities (including ropeways), forest offenses, fires, reforestation, forest products, seasoning, forest income, and forest expenditures. Experiments in raising conifers in combination with field crops have been started. Much resin continues to be collected and progress is reported in making an acceptable standard product. The Punjab Government has authorized adequate financing for developing forest resources, both by government loans and cooperative profit-sharing plans. The administration has been reorganized by creation of Chief Conservator and Utilization Conservator positions. The drought has affected the work of the Department by making labor more plentiful than before. The usual detailed statements of areas, receipts, etc., are a part of the report, and an abstract of the entire report, prepared by the Revenue Secretary to the Government, is a valuable feature.—*S. B. Show*.

2376. GRIST, D. H. Kapok. *Malayan Agric. Jour.* 10: 51-55. 1922.—*Eriodendron anfractuosum*, the source of the fiber Kapok, is not very common in the Malay Peninsula. In the Straits Settlements the number of trees seems to be only about 10,000. It has a great enemy in the white ant, which in the drier soil destroys it and is a limiting factor to its natural distribution. The tree fruits as young as 4 years. The life of the tree may be 50 years. The seed contains over 20 per cent of oil.—*I. H. Burkill*.

2377. HENRY, AUGUSTINE. The western larch in cultivation. *Quart. Jour. Forest.* 16: 161-174. 1922.—Western larch has not proved a successful introduction to Great Britain on account of the insular climate. It is susceptible to canker and in seedbeds yields, as a rule,

only a small proportion of vigorous seedlings. It is very intolerant of shade, narrow of crown, and unable to smother the grass which springs up in plantations. In its native habitat the larch differs remarkably from other species in the rapid ripening of cones, which shed their seed completely in September. The production of cones in most years is small, good crops being rare. Germination tests indicate a variation in the quality of the seed from 5 to 65 per cent. Seed steeped for 3 weeks gave excellent germination. As the cones ripen the heaviest seed fall out first so that collectors arriving after the cones start to open gather a larger proportion of small seed than the trees actually produce. Plantations in Great Britain show 5-10 per cent good trees, 10-15 per cent small trees, and 75-85 per cent of useless weaklings. The paucity of good trees in a plantation is the worst fault of *Larix occidentalis*. In Idaho the seed requires considerable moisture and heat up to 90°F. for successful germination. Under storage it retains its vitality well, having germinated 20 per cent at the end of 5 years. The tree has succeeded best in Great Britain on good deep soil and has thrived well of ground from which timber was just previously removed. It fails on stiff clay soils and on ground covered with dense matted grasses, rushes, etc. It does poorly on shallow soil over chalk. Slight evidence exists that the climate of eastern Great Britain is more congenial to the species than that of the western districts. In western Montana the larch grows closer together and has a more slender stem than European larch in Britain. Its volume and height is less in youth, but exceeds in height after 50 years and in volume after 70 years the European species. Larch was first introduced into Europe in 1881. The oldest trees are 42-47 feet high (apparently at age of 42-45 years). Only 1 has a straight stem; the others have curved stems, indicating sensitiveness to winds. Plantations and individual specimens of various ages on many sites do not in general give much promise or compare favorably with European and Japanese larch.—C. R. Tillotson.

2378. HULLAH, J. **Quinquennial report of forest administration in British India for the period 1914-15 to 1918-19 to which is appended the annual return of forest statistics for the year 1918-19.** 11-28. Simla. 1920.—This is a general summary of the work of the forest departments of British India for the 5-year period of the great war. Forest acreage, surveying, engineering, fire protection, grazing, planting, felling operations, income, forest entomology, and personnel are among the important subjects discussed. Planting progress in taungya plantations was made. Great progress in studies of regeneration of sal and deodar is reported. Graphic representation of some of the more important facts in the report is a valuable feature.—S. B. Show.

2379. JACOB, W. R. LEG. **Report on forest administration in the Andamans for the year 1919-20.** iii + 41 p. Calcutta, 1921.—Cutting of climbers in young stands was done on 2680 acres. The plantations, chiefly of teak and mahogany, have been tended; the area is now 4299 acres. The report includes the usual detailed tabulations showing areas, railway construction, output, receipts, expenditures, etc. In striking contrast to the other Indian provinces there were no forest fires and no unlawful fellings. A general abstract, such as is included in most Indian reports of similar nature, is not given.—S. B. Show.

2380. KAUTZ. **Die Verjüngung und Pflege der Buchen- und Fichtenhochwaldbestände im Schmalschlagbetriebe in der Oberförsterei Sieber (Harz).** [The regeneration and care of beech and Norway spruce highforest stands in small cutting operations in the Sieber forest range (Hartz Mountains).] Zeitschr. Forst.- u. Jagdw. 53: 348-406. Fig. 1-13. 1921.—The author discusses intensively past experience in regenerating beech and the present practice of securing beech regeneration under the small shelterwood-strip system; the care of pure beech stands by carefully conducted cleanings and thinnings, which retain the vigor of healthy reproduction; the proper conducting of thinnings in pole stands (40-80 years old); the regeneration and care of pure Norway spruce high-forest stands, also of mixed stands of beech and spruce; protection against destructive agents; and the relation of the small area operation to the continuous management systems, which include all systems which at no time leave the forest floor unstocked. The small area cutting system as compared with extensive

area and clear-cut systems strives mainly to secure better protection of the forest soil and reproduction against such dangers which are caused by logging and removal of the timber from forests.—*J. Roesser, Jr.*

2381. KOEHLER, ARTHUR. The identification of true mahogany, certain so-called mahoganies, and some common substitutes. U. S. Dept. Agric. Bull. 1050. 18 p., 13 fig. 1922.—A key is given for the identification of the woods of true mahoganies (*Swietenia* spp.), "African mahogany" (*Khaya* spp.), "Philippine mahogany" (*Shorea* spp.), and others, as well as *Betula lenta*, *B. lutea*, and *Liquidambar styraciflua*, the common substitutes. The woods, trade and common names, and sources of the various species are described, and a glossary of terms is given. The figures are photographs of the grain of various woods, magnified 7.5 diameters.—*J. Lincoln Cartledge.*

2382. LEE of FAREHAM, and G. G. LEVENSON GOWER. The ninety-eighth report of the commissioners of H. M. Woods, forests and land revenues, for the year ending March 31, 1920. 57 p., H. M. Stationery Office: London, 1920.—The total income for the year was £ 1,156,790, of which £ 128,187 was from timber, the balance from agricultural and house properties, mines, interest, etc. The expenditures were £ 477,859 of which £ 108,421 was for planting, cultural operations, etc. In accordance with various acts of Parliament, expenditures, incomes, leases, rents, etc., are given in great detail.—*S. B. Shaw.*

2383. LENT. Forstdüngungsversuche im Regierungsbezirk Sigmaringen. [Experiments in forest fertilizing in the government district Sigmaringen.] Mitteil. Deutsch. Landw. Ges. 37: 663-666. 1922.—This work was started in 1905, when the first plantings were made. Eleven treatments were tried including checks, all duplicated except 1 check plot and 1 plot to which 2000 pounds of calcium were applied. The tests included the turning under of 1 crop of alsike clover, the application of lime, phosphates, potash, and ammonia. To determine the effect of the treatments, the height of the trees (spruce) and the length of the terminal growth were measured every year from 1906 to 1920. Further height measurement was rendered impossible by the height of the trees; in 1922, the diameters at breast height were measured for every 3rd row. The results all pointed to the great value of phosphate fertilizers, but a comparison of growth in different years brought out the fact that growth was influenced by temperature and moisture more than by fertilizers.—*A. J. Pieters.*

2384. MATTOON, WILBUR R. Longleaf pine. U. S. Dept. Agric. Bull. 1061. 50 p., 22 pl. 1922.—A comprehensive discussion is presented of *Pinus palustris*, its range and importance, its second growth, rate of growth on various lands and under fire protection, and production of timber for cross-ties, cord-wood, and saw-timber. Various methods of turpentinizing and its effect on growth are described. Methods of reforestation, sowing and planting, protection against fire, hogs, insects, diseases, and other injuries are considered.—*J. T. Buchholz.*

2385. MAXWELL, HERBERT. Defoliation of oaks. Nature 110: 344. 1922.—The British oak (*Quercus robur* L.) has 2 distinct races, regarded by some botanists as distinct species (*Q. pedunculata* Ehrh. and *Q. sessiliflora* Salisb.). The latter, known as durmast oak, is the commonest indigenous form in western and northwestern Great Britain. It rarely ripens fruit, hence is less common in plantations, but is distinctly less susceptible to damage by *Tortrix*. The timber of the 2 forms is of equal quality.—*O. A. Stevens.*

2386. MILLISCHER, . Sur l'enrésinement. [Concerning the conversion of hardwood into coniferous forest.] Bull. Trimest. Soc. Forest. Franche-Comté et Belfort 14: 320-332. 1922.—A discussion is given of the transformation of hardwood coppice into coniferous high forest of fir. The retention of a mixture of beech, ash, and maple with the fir is desirable to the extent of 10-50 per cent depending on the needs of the community for firewood. The conversion should increase the owner's revenue 10 fold, and should be made wherever there is

a deep soil, north exposure, humid climate, with regular and abundant precipitation, and elevation from 500 to 1,000 m. The natural method is to take advantage of seedlings from neighboring seed trees which should be disengaged of the coppice at intervals of 10 or 15 years. The other method is by planting the fir after making a reproduction cutting in the hardwoods. Fir can be introduced by sowing or by planting, the latter in the autumn. Disengagement cuttings repeated every 5 or 10 years are indispensable to the success of the fir.—*J. Kittredge, Jr.*

2387. MILWARD, H. G. **Annual progress report of forest administration in the United Provinces for the forest year 1918-19.** 8 + 38 + cxvii + 7 p. Allahabad. 1919.—This annual report covers in detail the various phases of the forest work. It considers the forest area, income, utilization, reforestation offenses, fire protection, grazing, and forest income. Insect damage to sal, and to chir pine following fire, is noted. A brief review of the 5-year period 1914-15 to 1918-19 shows as outstanding features the increase in area of reserved forest from 5,410 to 7473 square miles, the great investment in utilization improvement projects, the increase of forest offenses from 2997 to 4421, increase in output of timber and fuel from 20,105,000 to 26,355,000 cubic feet, the great increase in income, already noted, and the excellent success in afforestation of denuded areas on over 3000 acres. A review by the Secretary to Government is a valuable feature of the report.—*S. B. Show.*

2388. MONNIN. **Sur la qualification des bois.** [Concerning the qualifications of woods for different uses.] Bull. Trimest. Soc. Forest. Franche-Comté et Belfort 14: 347-357. Fig. 1-11. 1922.—Descriptions and illustrations are given of the wood structure of European fir, American spruce, white pine, mahogany, red birch, black walnut, ash, and oak. Methods of determining the coefficient of elasticity, the modulus of rupture, and resistance to shock are given. A table compares the characteristics of fir, spruce, and larch woods (all from the same station in the Alps) as to appearance, shrinkage, moisture content, specific gravity, compression, bending, resistance to shock, and transverse shearing.—*J. Kittredge, Jr.*

2389. OSMASTON, B. B. **Report on the forest administration of the Central Provinces (India) for the year 1919-20.** I. The report. 7 + 32 p. II. Statistical statements. lxiii p. Nagpur, 1921.—The annual summary of the work of the Forest Department shows there was no change of consequence in the constitution of State forests, which cover $\frac{1}{3}$ of the area of the province. Among the important subjects considered are boundary surveys, forest offenses, working plans, road construction, forest fires, planting, grazing, forest utilization, and forest income. Taungya plantations total 7946 acres. Collection and revenues from lac are discussed. Revised scales of pay for subordinates were put into effect. The personnel, especially in the higher grades, is felt to be inadequate. Part II of the report summarizes in detail the various phases of the work of the Department. A summary by the Revenue Secretary precedes the Conservator's report.—*S. B. Show.*

2390. PAERELS, J. J. **Cocoa-cultuur op Java.** [Coca growing in Java.] *Cultura* 34: 328-330. 1922.—*Erythroxylon coca*, the Peru coca, and *E. novagranatense*, the Java coca, are considered. The latter grows from sea level to an elevation of 1000 m. and more. A moist climate is beneficial for leaf production. The seed lose their germinating capacity within 2-3 weeks. Seed treatment and nursery practices are discussed. Coca is also grown as a secondary crop, especially between coffee and *Hevea*. The first harvest of leaves takes place when the trees are pruned to a height of 1 foot. When plants are 3-3 $\frac{1}{2}$ feet high they are cut back to a height of 2-2 $\frac{1}{2}$ feet.—When leaves are harvested they are spread out to prevent fermentation. The more quickly the leaves are dried or the lower the temperature, the less the alkaloid is decomposed. When picked in early morning, they should be dried the same day. Leaves are also dried artificially. After drying they are pulverized and packed. In Java 600-750 kgm. per bouw (=0.70 hectare) are produced. Most of the crop is sent to Amsterdam (265,000-910,000 kgm. yearly). Some is sent to the U. S. A.—*J. C. Th. Uphof.*

2391. PARNELL, R. **Progress report on forest administration in the Northwest Frontier Province for the year 1919-20.** 2 + 2 + 15 + xxviii p. Peshawar Cantonment, 1920.—The

area of reserved forests has remained constant at 159,925 acres, and protected forests at 77,519 acres. Forest working plans, forest offenses, protection, reforestation, improvement cuttings, felling operations, forest products, forest income, and forest expenditures are among the important subjects discussed. Deodar appears to compete unsuccessfully with blue pine, the regeneration of which, as well as of chil pine, is excellent.—The question of reorganization of the Forest Department is still unsettled. The customary detailed tabulations covering all phases of the work of the Department are included in the report, and reviews by the Revenue Secretary and the Inspector-General of Forests are valuable features.—*S. B. Show.*

2392. RECORD, SAMUEL J. **Notes on woods.** Science 55: 266-269. 1922.—West Indian boxwood may refer to wood from (1) *Aspidosperma Vargasi* DC., the first on the market, now largely replaced by (2) *Casearia praecox* Griseb.; and (3) *Phyllostylon brasiliensis* Capanema (= *P. rhamnoides* Taubert = *Samaroceltis rhamnoides* Poisson), the wood of which is of inferior quality. It is often stated incorrectly that West Indian boxwood comes from *Tabebuia (Tecoma) pentaphylla* B. & H. f. Brazilian tulipwood is supplied by *Physocalymma scaberrimum* Pohl. Coffeewood for umbrella handles comes from Venezuela and the best evidence points to *Caesalpinia Ebano* Karst. as its source. "Rosewood" covers several different woods, so named from color or scent. Surinam rosewood, or "rozenhout," the source of an essential oil, is established as *Aniba* sp. (near *A. panurensis* Mez.). True Brazilian rosewood is *Dalbergia nigra* Fr. All. and trade varieties are based on color variations only. Honduras "rosewood," the best for xylophone bars, has not been identified beyond being one of the Leguminosae, possibly a *Dalbergia*. Cocobolo, used for knife handles, comes from several countries. In Panama it is from *Dalbergia retusa* Hemsley, in Nicaragua from *D. hypoleuca* Pittier in ed., while the wood from Mexico is probably from a new species. "Redwood" of Panama is *Platymiscium dubium* Pittier; of Brazil it is *Brosimum paraense* Huber. The latter promises to be much like, if not identical with, "satiné" of French Guiana which has been named *Ferolia guianensis*. Kakatara-balli, a dull-white wood of British Guiana, seems to be from some species of *Ilex*.—*C. J. Lyon.*

2393. TRAFFORD, F. **Annual progress report on forest administration in the province of Bihar and Orissa for the year 1918-19 with a summary of progress during five years 1914-15 to 1918-19.** 69 + 5 p. Patna, 1919.—This report considers forest area, offenses, protection, grazing, planting, timber sales, and forest income. Teak and casuarina plantations were increased somewhat, and taungya plantations are promising. A good seed year is reported for sal though regeneration was retarded by evergreen undergrowth. The summary for the 5-year period ending with the year under report shows considerable progress in reorganization of the department; the personnel is inadequate, otherwise the record is one of fairly steady progress, with the financial results particularly striking. A review of the report by the Secretary to Government and a map of the province are valuable features of the report.—*S. B. Show.*

2394. TRAFFORD, F. **Progress report of the forest administration in the Province of Assam for the year 1920-21.** 15 + 49 + 2 p. Shillong, 1921.—Since the forest year is being made to coincide with the fiscal year, this report covers a 9-month period in the work of the forest department. A good seed crop of sal and other important species is reported. Experiments in natural regeneration of sal by a combination of fire and grazing were inconclusive, but similar studies in the evergreen forests of the east promise success. Taungya plantations of sal were made on a minor scale. An area of 13,084 acres of sal forests was worked under improvement fellings. The report considers gross and net yields of different operations, areas, construction work, offenses, fires, fire protection, personnel, expenditures, etc. A valuable summary of the more important features of the year's work, prepared by the Revenue Secretary to Government, is given. M. A. W. Blunt, one of the veterans in the service, and formerly conservator of the western circle, has retired from active service.—*S. B. Show.*

2395. TREBELJAHR. *Die taxatorische Behandlung von Mischbeständen.* [Management of mixed stands.] *Zeitschr. Forst- u. Jagdw.* 63: 616-626. 1921.—In this reply to Denzin's article [see Bot. Absts. 11, Entry 2354], Trebeljahr contends that the division of mixed stands into distinct working sections by species is theoretical, impracticable, and complicates the plan. In mixed stands the division into regular working sections should be based on the age classes and rotation period of the principal tree; and all species should fall into one working section. Continuity of management is dependent upon such age class division. The new arrangement does not entail more bookkeeping. The management plan is not a statistical work, which Denzin claims as an advantage of the former system.—*J. Roeser, Jr.*

2396. TREBELJAHR. *Kieferndauerwaldwirtschaft.* [Continuous forest management in pine.] *Zeitschr. Forst- u. Jagdw.* 53: 286-294. 1921.—This article constitutes another chapter in the dispute between Möller and Trebeljahr in which the latter replies to Möller's article [see Bot. Absts. 11, Entry 2394]. Trebeljahr is opposed to the continuous management system in pine as practiced at Bärenthoren for he regards it as impractical when applied in extensive state forest operations. Leaving the litter on the soil undoubtedly raises the site quality, but Trebeljahr contends that this is not a characteristic of the continuous management system. Since the author is a soil-rental theorist he does not support Möller's authorities, such as Fricke, von Hagen and Borggreves; he analyses the latter's formula and shows that it is untenable since it does not consider intermediate yields.—*J. Roeser, Jr.*

2397. U. *Die Zukunft der Jugoslawischen Wälder.* [The future of Yugoslavian forests.] *Wien. Allg. Forst u. Jagd Zeitg.* 40: 141-142. 1922.—The author covers the legal rather than silvicultural aspects and criticizes certain governmental forest regulations and presents systems of taxation as fostering short-sighted policies.—*F. S. Baker.*

2398. WEBER, HEINRICH. *Grundlinien einer neuen Forstwirtschaftsphilosophie.* [Foundations of a new philosophy of forestry.] 116 p. Tübingen, 1919.—Part I deals with laying the foundations of forestry science. In this the author attempts to analyze and answer 3 questions: What is science in general? What is the object of forestry science? What is forestry science? Part II deals with the system of forestry science, both in its immediate and in its historical development. Part III deals with the methodology of forestry science (research methods), both in its present status and in its historical development. Weber's system of forestry science is built upon human consciousness itself. The end products of thought, volition, and feeling, which constitute consciousness, are respectively the natural (both mathematical and biological) sciences, the volitional or sociological sciences, and the sciences underlying the arts. Each works with its own methods; by means of logic, ethics, and aesthetics respectively. These 3 together with psychology may be said to constitute the main body of philosophical thought. The natural sciences include mathematics, physics, chemistry, botany, zoology, meteorology, climatology, geology, etc.; the volitional sciences include political science, sociological science, and economics; the so-called art sciences are included in the term "forest aesthetics." Forestry science presents 3 main aspects—the fundamental aspect, meaning the fundamental sciences, the norm of forest production, and lastly forest practice. The norm is built upon the fundamental sciences, and upon the norm is built forestry practice. The latter, reciprocally, has a controlling effect upon the norm. The norm is considered the keystone of the entire philosophical structure.—*Richard H. D. Boerker.*

2399. WITT, D. O. *Annual progress report on forest administration in the Province of Bihar and Orissa for the year 1919-20.* 59 + 3 p. Patna, 1920.—Details of the work of the forest department are covered. The report discusses forest area, offenses, fire protection, working plans, land acquisition, cooperative work, and forest income. A review by the Secretary to Government is a valuable feature of the report.—*S. B. Show.*

GENETICS

(See also in this issue Entries 2229, 2239, 2253, 2262, 2286, 2480, 2482, 2486, 2492, 2501, 2505, 2507, 2514, 2515, 2547, 2561, 2626, 2665, 2845, 2848, 2857, 2861)

2400. ANONYMOUS. Hybrid *Nymphaeas*. Missouri Bot. Gard. Bull. 10: 127-131. Pl. 18-20. 1922.—Water lilies have been cultivated since 3000 B. C. Schweinfurth studied specimens from funeral wreaths of Rameses II in comparison with the white nocturnal (night-blooming) *N. Lotus*. It is concluded that species have not noticeably changed in 4000 years. All tropical diurnal (day-blooming) water lilies are colored, excepting *N. gracilis* from Mexico. The African species *N. ovalifolia* has white petals tipped with blue and pink. White is not recessive in crosses. *N. ovalifolia* in crosses segregates its type in F_2 . *N. gracilis* in crosses does not segregate that type.—The cross *N. ovalifolia* \times *N. "Mrs. Edwards Whitaker"* and the reciprocal cross were made. The cross with *N. ovalifolia* as seed parent produced both albinos and "Whitaker." Selection fixed the dominant albino character in 3 years' self pollination. Self pollinated "Whitaker" yielded a light campanula-blue type also produced as a hybrid from *N. castaliiflora* \times *N. castaliiflora*. Another hybrid of uncertain parentage is described. Trade designations are used in the discussion.—J. Ben Hill.

2401. ANONYMOUS. Nocturnal hybrid water-lilies of the late James Gurney. Missouri Bot. Gard. Bull. 10: 147-150. Pl. 24-26. 1922.—Seven nocturnal (night-blooming) hybrid water-lilies, the result of work of the late James Gurney, are described. Parentage is uncertain in all cases, 2 species, *Nymphaea Lotus* and *N. rubra*, comprising the original stock. Selections were made of promising hybrid seedlings. One hybrid derived from parents of the lotus type was both nocturnal and diurnal (day-blooming) indicating the possibility of obtaining diurnal segregates from nocturnal types.—J. Ben Hill.

2402. ANONYMOUS. The present position of Darwinism. Nature 110: 751-753. 1922.—In this summary of the discussion at the joint meeting of the botany and zoology sections of the British Association for the Advancement of Science, natural selection is attacked by J. C. WILLIS from the geographical distribution point of view and by UDNY YULE from the results of statistical analysis. It is contended that no proof exists for the mechanisms Darwin assumed to account for natural selection; also that the hypothesis of "age and area" and "size and space" offer a better explanation of geographical distribution and evolution than does natural selection. Distribution is regarded as a question of dispersal and time acting at a uniform rate. Willis regards large mutations of greatest importance in evolution.—Yule discusses statistically the theory of "age, size, and space." Genera "throw" species whose numbers increase in geometrical ratio with time. J. STANLEY GARDINER approves the thesis of "age and area." C. TATE REGAN criticizes the statistical work of Yule and Willis claiming Darwin's work had stood the test. CHALMERS MITCHELL considers that Willis has presented merely a caricature of natural selection. H. WAGER dismisses fluctuating variations as of no evolutionary value but says mutations need not be large. He directs attention to an alternate title for "origin of species," namely, "preservation of favored races."—A. C. SEWARD criticizes "age and area" theory pointing out that conifers and ferns in restricted areas are the oldest forms. E. B. POULTON states that in African butterflies the younger form has a greater distribution than its ancestral type. A. B. RENDLE considers multiplication of forms in geometrical progression unlikely in limited space. He regards as difficult the differentiation between useful and useless characters. R. RUGGLES GATES emphasizes the importance of extinction of forms as an evolutionary factor. JULIAN HUXLEY states that in the Gipsy moth apparently useless characters are correlated with physiological differences harmonizing with environment.—W. JOHANNSSEN thinks that most geneticists are agnostics as to the mechanism of evolution. W. J. DAKIN believes the faculty of evolution is a character of organisms as are irritability and reproduction. J. Stanley Gardiner agrees that evolution is an inherent property of protoplasm.—J. Ben Hill.

2403. ANONYMOUS. **Testing of new varieties of the potato for immunity from wart disease.** Scottish Jour. Agric. 5: 306-311. 1922.—Samples of potatoes to be tested were first sprouted in boxes, and tubers with sprouts differing in color from the bulk of the sample were discarded. Observations were made to determine trueness to variety and to detect the occurrence of diseases other than wart, notably blight, corky scab, mosaic, and leaf-roll. Samples of new varieties of potatoes are tested for at least 2 seasons, and if they satisfactorily pass the trials a certificate for immunity to wart is granted. Of the 80 American varieties under test, 18 named sorts and 3 seedlings were immune, and 3 additional seedlings were doubtfully immune. The immune varieties comprise 10 types as follows: Irish Cobbler (4), Early Harvest, Ehnola, Perfect Peachblow, Early Manistee, Green Mountain (6), Netted Gem, Keeper, Northern King, M'Cormick. Of 22 varieties from Germany, 4 proved to be immune. A synopsis of the American Report on British Varieties Sent to the United States in 1920 is given as well as a brief note on the German Report on British Varieties.—*J. A. Faris.*

2404. ANONYMOUS. **Wart disease of potato immunity trials.** Gard. Chron. 72: 229. 1922.—Additional facts regarding immunity trials at the testing station of the Scottish Board of Agriculture are given [see preceding entry]. Tests are made with single tubers and also with 6 tubers of each kind. In the single tuber tests numbers of pedigree seedlings of both immune and non-immune varieties were included to obtain knowledge of the probable percentage of immune types which might be expected in either case. Selfed immune varieties produced a large number of immune seedlings. Crossing a non-immune with an immune variety (President \times Flourball) showed about 40 per cent of immune individuals after 2-years' test, but crossing 2 immunes (Majestic \times Flourball) gave a percentage of 70-80 of immunes.—*J. A. Faris.*

2405. AUCHTER, E. C. **Apple pollen and pollination studies in Maryland.** Proc. Amer. Soc. Hort. Sci. 18: 51-80. 1921 [1922].—Sterility tests made in 1919 and 1920 of 66 varieties of apples showed that 45 were self-sterile, 12 self-fertile, and 9 partially self-fertile.—In 1919 approximately 1000 blossoms (in 1920, 500) of each variety, in the pink stage, were inclosed in manila sacks. Sacks were removed after flowering was over and a record made of fruits; this record was repeated after the "June drop." In all cases 1000 unbagged blossoms were counted to serve as a check and to indicate the "normal set." Removing bags and brushing the stigmas did not increase set of fruit in 4 self-fertile varieties, nor did it cause setting of fruit in self-sterile varieties. Bagging is, apparently, a safe method of testing self-sterility even though stigmas are not brushed. To insure cross-pollination, varieties should bloom at approximately the same time. Except for very early and very late blooming varieties there is sufficient overlapping of periods to permit cross-pollination. Blooming records for 107 varieties covering 1-8 years show that dates of bloom and length of periods vary in different years and are influenced by many factors; the average for a number of years is a safe index. Intersterility studies indicate that Stayman Winesap \times Winesap and Stayman Winesap \times Arkansas, as well as the reciprocals, are intersterile. Winesap and Arkansas are apparently intersterile. A test of Early Ripe, Red June, Red Astrachan, Oldenburg, and Bloomfield showed in general that early varieties are cross-fertile, although pollen of Oldenburg and Bloomfield used in Early Ripe failed.—Pollen from 19 varieties was used on Lawver; 15 varieties failed and 4 gave success, the percentages, ranging from 0.6 to 5.37, suggesting that cross-sterility may be more serious than supposed.—Slightly higher pollen germination percentages were secured in 10 than in 2, 5, and 15 per cent sugar solutions. Pollen of most varieties germinated equally well whether listed as self-fertile or as self-sterile. Stayman Winesap and Arkansas pollen gave practically no germination.—The set of fruit increased from nearly 2 to 5-fold when pollen from larger buds was used. Pollen from small buds did not germinate as soon or as well as did pollen from large buds. Pollination of large buds gave better set of fruit than pollination of small buds. Immediate pollination gave better results than delayed, especially in warm weather. The author concluded that pollen remains healthy and viable for long periods if kept dry and at proper temperature. Pollen can endure lower temperatures than pistils. Pollen from trees subjected to 20 and 22°F. when in bloom gave good percentage

germination, but germinated more slowly than normal pollens. Time of day is not important unless decided changes in weather have occurred.—C. S. Crandall.

2406. BABCOCK, E. B. Bud selection and frequency of mutations. Better Fruit 16⁵: 9-10. 1921.—There is little definite information regarding the frequency of bud mutations in varieties of deciduous fruits. Propagation from high-yielding trees is commended, but trees so propagated should not be offered as anything more than first class stock until it has been proved that the high-yielding character of the parent tree has been transmitted. The question as to whether yield of varieties of deciduous fruits can be increased through bud selection is still unanswered and data from careful experiments are needed. Bud mutations appear to be frequent in certain citrus varieties, but it should not be inferred that they occur with equal frequency in apples or other deciduous fruits. Deciduous varieties have arisen as bud mutations, but the number is small and it is fair to infer that mutations resulting in high productivity are rare. Experiments have been limited, but thus far have tended to increase doubt as to the practicability of increasing yield of standard deciduous varieties through bud selection. Advertising stock grown from high producers as insuring high-yielding orchards should be discouraged until results of definite experiments have proved to what extent trees thus propagated excel first-class nursery stock. Bud selection should be encouraged, but the practice does not warrant claims to unusual merits in nursery stock. Keeping performance records of orchard trees is commended.—C. S. Crandall.

2407. BANTA, ARTHUR M., and L. A. BROWN. More eyeless Cladocera. Amer. Nat. 56: 568-571. 1922.—In crowded cultures of daphnids 2 eyeless individuals have occurred in *Moina rectirostris* and 9 in *M. macrocopa*. All showed a reduced optic ganglion and some had abnormal antennae. Several thousand descendants of these 11 eyeless individuals together with some of their collaterals were raised but all were normal, thus showing that eyelessness was not transmitted. External factors are suggested as being responsible for these abnormalities.—D. D. Whitney.

2408. BERTAUX, A. Un cas d'hermaphroditisme androgynoid. [A case of androgynoid hermaphroditism.] Bull. et Mem. Soc. Anat. Paris 1922: 93-94. 1922.—A child of 12 years, previously regarded as a girl, was operated upon for inguinal hernia when a testis was revealed in the canal of Nuck. A brother of 14 is normal as is also a sister of 3, except that the latter has a small strand of tissue bridging the urinary meatus.—C. H. Danforth.

2409. BLARINGHEM, L. Héritéité anormale de la couleur des embryons d'une variété de pois (*Pisum sativum* L.). [Abnormal inheritance of the color of the embryo of a variety of garden pea.] Compt. Rend. Acad. Sci. Paris 174: 877-879. 1922.—Some striking irregularities in the inheritance of embryo color in garden peas are reported. Some lines show the simple 3:1 segregation of yellow to green in the 2nd generation; but certain other strains give irregular ratios in which green is dominant to yellow [see Bot. Absts. 1, entries 1314, 1315]. Such irregular strains are affected by climate, nutrition, and maturity and furnish excellent material for the study of the effect of environmental conditions upon the expression of a character. Because of this reversal of dominance in peas it is necessary to resort to severe selection of lines in order to verify the original work of Mendel.—H. C. McPhee.

2410. BLUHM, AGNES. Zur Erblchkeitsfrage des Kropfes. [The question of inheritance of goitre.] Arch. Rass.- u. Gesellschaftsbiol. 14: 1-9. 1922.—In any study of goitre it is important to distinguish between endemic and sporadic cases. Endemic goitre it would seem may not be hereditary while sporadic forms commonly are. Since the manifestations of goitre are of varying degrees, it is necessary in any thorough-going study of heredity of the condition to examine not only the obviously goitrous members of a family but also those who may seem to be normal. Furthermore it is important to know where each individual has lived at each life period in order to determine the likelihood of endemic ('acquired') goitre. The author endeavors to present a family history which meets these requirements. The

progenitress, of Dutch descent on her father's side, probably had a slight goitre. Of 20 female descendants in 3 generations, 4 have obvious goitres (1 with Basedow's disease); 5, goitres apparent to a trained observer; and 5, goitres recognizable only by palpation or slight thickening of the neck. The remaining 6 either died in infancy or are too young to show the defect. It has not appeared in any male descendant though some have seemed to transmit it. The condition is definitely hereditary but none of the suggested hypotheses offered a satisfactory explanation of its mode of transmission. Nevertheless the author feels that despite its inherent difficulties the heredity of goitre furnishes a promising subject for study in the field of hereditary pathology.—*C. H. Danforth.*

2411. BOUGET, JOSEPH. *Sur les variations de coloration des fleurs réalisées expérimentalement à haute altitude.* [Upon variations in flower color experimentally secured at high altitude.] *Compt. Rend. Acad. Sci. Paris* 175: 900-901. 1922.—Experiments in plants at 2860 m. altitude have shown that the brilliant flower coloring of alpine plants is due to a high percentage of moisture in the atmosphere surrounding the plant and to the intensity of the sun-light reflected from the snow during the flowering period. Temperature had little effect on coloration. The diminution in light intensity resulted in less bright colors.—*J. L. Collins.*

2412. CARON, VON. *Züchtung und Anbau deutscher kleberreicher Winterweizen und ihre Backfähigkeit.* [Breeding and cultivation of German high-gluten winter wheats and their baking qualities.] *Beitr. Pflanzenzucht* 5: 158-168. 1 pl. 1922.—In an attempt to make Germany less dependent on foreign countries for high-gluten wheat, breeding operations were begun in order to produce a new variety suitable both in yield and baking quality, present varieties being inadequate. Hybrids were made in 1911 between Nordstrand, a not very late ripening, northern-grown variety, and Saumur, an early ripening, high-gluten, spring variety from southern France. These 2 parents were morphologically similar, having small, lax, sometimes nodding spikes. This cross gave a squarehead form (thick, compact spike) with reddish-brown, glassy kernels. The dark reddish-brown form was constant to 1914, when reported. Analyses showed the protein content of 2 selections made as 18.08 and 18 per cent, while Nordstrand had 10.87 and Saumur 11.01 per cent. In gluten they were nearly equal to Manitoba wheat, the best foreign kind, and much superior to the ordinary German wheats. They ripen about 14 days earlier than Nordstrand, and a month earlier than the German squarehead wheat. The selections are apparently winter-hardy, as indicated by spreading growth, and not affected by loose smut. The kernels are larger than in the parents. A new hypothesis of inheritance is formulated in which the positive bio-electron of the protein gene of the new individual is lessened by the negative bio-electron of the protein genes of the father and mother, while the negative bio-electron of the protein gene of the new individual absorbs the positive bio-electrons of the parents. [A discussion follows on pages 169-170.] —*C. E. Leighty.*

2413. COFFMAN, F. A. *Pollination in alfalfa.* *Bot. Gaz.* 74: 197-203. *Fig. 1-5.* 1922.—Pollination was studied with reference to 4 arbitrarily chosen stages in floral development: "straight bud" (5-6 mm. in length), "pointed bud" (6-10 mm.), "hooded bud," and "erect standard." It was found that the flowers begin to shed pollen in the pointed bud stage. Since in ordinary hybridizing work dependence is placed upon tripping in the hooded bud stage and subsequent removal of the pollen by washing, it is pointed out that no certainty may be gained that self-pollination has not taken place. The author states that emasculation earlier than the pointed bud stage is practically impossible.—*B. W. Wells.*

2414. FETSCHER, R. *Über die Erbllichkeit des angeborenen Klumpfußes.* [Heredity of congenital clubfoot.] *Arch. Rass.- u. Gesellschaftsbiol.* 14: 39-52. 1922.—Clubfoot is found in about 1 case in 1,000, and commonly in the offspring of normal parents, which suggests that if hereditary it is recessive. That it is in fact hereditary is indicated by a study of 25 family groups. Data previously reported by Besselhangen showed that in the general run of cases 63.7 per cent are males and 36.3 per cent females. The author finds a similar distribution

(67.2 per cent male, 32.8 per cent female), but notes that there is a concomitant disturbance in the sex ratio since in the families studied there are 2 males to 1 female. It might appear from this that the actual incidence of clubfoot is the same for both sexes were it not that such an assumption seems to be precluded by the extensive data of Besselhagen. However, the observed departure from the normal sex ratio is significant and an attempt is made to explain the whole situation on the hypothesis of a special kind of non-disjunction resulting in 3 types of viable eggs. When fertilized by sperm from a heterozygous male such eggs would be expected to produce 3 males to 2 females and among the affected individuals 2 males to 1 female. These expectations agree fairly well with observations except that the actual number of offspring with clubfoot is too small, being, when both parents are heterozygous, about $\frac{1}{20}$ instead of $\frac{1}{3}$ of the children. This discrepancy could be explained by postulating 1 additional recessive factor or 2 dominant ones, which would reduce the expected cases to about the number observed. The author recognizes certain weaknesses in this (rather involved) hypothesis, which is presented merely as a tentative suggestion.—*C. H. Danforth.*

2415. FRATEUR, J. L. *Mendelsche synthetisvormen bij de dieren.* [Mendelian synthetic forms in animals.] *Genetica* 4: 235-246. 1922.—The results of a series of hybridizing experiments with rabbits and the domestic fowl are reported. Phenotypes differing from the ordinary dominant and also from the intermediate F_1 forms can be of 2 classes: (1) an entirely new type, as the result of complementary factors; (2) a mosaic type, through a juxtaposition of 2 dominant characters, 1 of which is possessed by each of the parental types. In the F_2 a dihybrid of class 1 would give the following ratio: 9 N, 3 P, 3 P_1 , 1 N_1 . Crosses of hybrids carrying complementary factors (class 1) as well as those with factors in juxtaposition (class 2) produce corresponding numbers of genotypes in F_2 .—*A. R. Saunders.*

2416. FRECKMANN, W. *Grassamenbau und Gräserzüchtung.* [Grass-seed production and grass breeding.] *Beitr. Pflanzenzucht* 5: 118-128. 1922.—This is a discussion (at plant-breeding conference in 1914) of the practical question of grass-seed production, and a plea for more breeding work on grasses and clovers. The need for better-yielding varieties of hay crops is pointed out, also the use of kinds best adapted to conditions, which would allow the production of sufficient forage on the present acreage of meadow and pasture land and yet maintain the present grain acreage. A discussion follows on pages 128-134.—*C. E. Leighty.*

2417. GARBER, R. J. *Inheritance and yield with particular reference to rust resistance and panicle type in oats.* *Minnesota Agric. Exp. Sta. Tech. Bull.* 7. 62 p., 6 fig. 1922.—A study was made in oat crosses of the inheritance of panicle type and pollen abortion in relation to host reaction to stem rust. A study was made also to determine the correlation between rust reaction and yield and between panicle type and yield. Crosses were made between 2 open-panicled pure lines of oats, Victory and Minota, which are susceptible to stem rust, and a side-panicled pure line, white Russian, which is resistant. The crosses and parents were grown in the field under artificially induced epidemic conditions. Rust resistance behaved as a dominant character depending on 1 main genetic factor for its expression. In the F_2 generation of both crosses, Minota-White Russian and Victory-White Russian, there were 2,340 resistant and 704 susceptible plants. Of 377 F_3 families tested, 106 bred true for resistance, 175 segregated in the ratio 3 resistant to 1 susceptible, and 96 bred true for susceptibility. The F_1 plants are open-panicled but not to the same degree as the open-panicled parents. Of the 377 F_3 families tested, 98 bred true for open panicle, 213 showed segregation, and 66 bred true for side panicle. Rust reaction and panicle type are nearly, if not completely, independent in their inheritance. The Victory parent produced 12.4 per cent aborted pollen. Minota and White Russian produced 1.0 and 0.9 per cent aborted pollen, respectively. Of 250 F_2 plants in the Victory-White Russian cross, 7 produced percentages of aborted pollen within the range exhibited by the Victory parent. In the F_2 generation of the Minota-White Russian cross, rust infection caused a reduction in yield of 12 per cent in the open-panicled plants and 34 per cent among the side-panicled plants; and in the Victory-White Russian cross, 37 per cent among the open-panicled plants and 24 per cent in the side-panicled plants. In the F_3

generation the average percentages of reduction of yield as a result of infection with stem rust were 24, 14, and 37, 30 in the 2 crosses, respectively. In the Victory-White Russian cross the average yield per plant for the resistant forms was 16 per cent greater for the open-panicled types than for the side-panicled types; and for the susceptible forms the yield was 15 per cent greater for the side-panicled types. In the Minota-White Russian cross the average yield in the resistant forms was 14 per cent greater for the open-panicled than for the side-panicled types; and for the susceptible types the open-panicled forms yielded 25 per cent more than the side-panicled forms.—*Fred Griffiee*.

2418. GARBER, R. J. **Origin of false wild oats.** Jour. Heredity 13: 40-48. 1922.—The appearance of false wild oats in cultivated varieties of *Avena sativa* and *A. orientalis* has been explained by Nilsson-Ehle on the basis of loss-mutation and by Tschermak and Zade on the basis of natural crossing. False wild oats were found at University Farm, St. Paul, in 3 cultivated varieties of oats, Victory, Aurora, and Garton 784. The false wild oats in Victory were found in a plant row seeded from a panicle selected the previous year as typical Victory. The false wild plants differed from Victory only in respect to awn development, articulation of seed, and pubescence, and on the basis of these characters homozygous false wild, heterozygous false wild, and Victory plants were distinguished from one another. Victory types and homozygous false Victory bred true. The heterozygous false Victory gave 54 Victory types, 163 heterozygous false wild, and 80 homozygous false Victory. The false wild oats found in Garton 784 behaved similarly to those found in Victory. Homozygous false Garton 784 and homozygous Garton 784 bred true. The heterozygous false Garton 784 gave 81 Garton 784, 122 heterozygous false Garton 784, and 55 homozygous false Garton 784. Summing the results of the Victory and Garton 784, the progeny of the heterozygous false wild types approximates very closely a 1:2:1 ratio.—The false wild oats found in Aurora have the same characteristics of the Aurora except in awn development, articulation of seed, and pubescence.—Crosses between Garton 748, a variety very similar to Garton 784, and wild oats segregated for other characters than awn development, articulation of seed, and pubescence. The controlled crosses of cultivated varieties with the wild oats segregate for other characters than the awn development, articulation of seed, and pubescence, and that these latter characters are due to 1 main genetic factor is taken as evidence against the explanation of the appearance of false wild oats as due to natural crossing and in favor of the view of mutation.—*Fred Griffiee*.

2419. GATES, R. R. **Interspecific sterility.** Nature 110: 179-180. 1922.—Bateson [Nature 110: 76. 1922.] lays insufficient emphasis on certain facts. Considering organisms in general interspecific sterility appears not so general as was formerly assumed. Among animals it is more widespread. The case of *Drosophila melanogaster* × *D. simulans*, which gives sterile hybrids although the 2 are similar and have similar chromosome groups, corresponds exactly with Bateson's conception of interspecific sterility. But it is an extreme case.—While agreeing that tetraploids frequently do not breed freely with diploids, Bateson regards the applicability of such an example doubtful because a tetraploid must be considered "an unresolved pair of twins," hence not a "specifically distinct organism." Bateson scarcely recognizes the intimate nature of the union involved. This union in *Oenothera gigas* not only increases cell size but alters cell shapes. Genetic behavior of *O. gigas* indicates some change in germ plasm in addition to chromosome doubling. This is shown by comparing *O. gigas* with Winckler's *Solanum* tetraploids, obtained by grafting; the latter are merely stouter without alteration in shape of parts or organs.—Wide occurrence and evolutionary significance of tetraploid species is not generally recognized. Tetraploidy bars free crossing with diploid forms in any line of descent. Tetraploid forms may be regarded as mutations significantly accompanied by partial interspecific sterility. The cross-breds with unbalanced chromosome groups tend to be eliminated, while each pure form perpetuates itself.—*E. B. Babcock*.

2420. GRIFFITH, C. R. **Are permanent disturbances of equilibration inherited?** Science 56: 676-678. 1922.—White rats were horizontally rotated day and night, 60-90 times a minute, for several months. Some weeks after removal there appeared circular movements of the body

and twistings of the head, and some died from an affection of the ear. When mated, some of the progeny, which had never been rotated, showed symptoms of the same kind. Further investigations with a new stock are in progress.—*John Belling*.

2421. GUYER, M. F. [Rev. of: NEWMAN, H. H. *Readings in evolution, genetics and eugenics*. xviii + 523 p. Univ. of Chicago Press: Chicago, 1921.] *Science* 56: 451. 1922.—Presentation in a single text book of materials necessary to be gleaned from numerous volumes. The book is not a patchwork but surprisingly unified. Minor mistatements and contradictions in former separate treatises are reduced to a minimum. A glossary of scientific terms is needed. For courses in evolution, variation should be given before or along with causal factors of organic evolution. Evidences from morphology would be better presented before those from paleontology. Chapters on neo-Mendelian heredity, sex-linked and other kinds of linked inheritance, and linkage and crossing-over are too difficult for the beginning student. "For the general student this is the most complete and acceptable one-volume account of organic evolution and allied subjects in print."—*D. F. Jones*.

2422. HANISCH. *Tätigkeitsbericht der Pflanzenzuchtstation Ung.-Brod*. [Accomplishments of the plant breeding station of Broder, Hungary.] *Wien. Landw. Zeitg.* 72: 95-96. 1922.—A winter hardy rye ripening 6-8 days earlier than the parents was selected out of a cross, Hanna × Blue Petkuser. The hybrid possesses other desirable commercial qualities. Several crosses with summer barley are described, and types which are superior in adaptability to heavy soils and freedom from lodging are being selected. In pea-hybridization studies, one of the objects is to secure resistance to black aphid, one of the most serious enemies of pea culture. Potato breeding and variety testing studies are in progress, the object being to find varieties better adapted to Hungary's heavy soils.—*F. Weiss*.

2423. HARLAND, S. C. *Inheritance in Ricinus communis L.* *Jour. Genetics* 12: 251-253. 1922.—Further data are presented on the segregation of factors in the castor-oil bean [see *Bot. Absts.* 1, Entries 249; 2, Entries 939, 952]. By back-crossing, factors *M* (mahogany) and *B* (bloom) were found to be linked and factors *G* (green) and *B* and also *M* and *G* to be independently inherited. No repulsion was found between factors *S* (spines) and *G* although more data are necessary to establish this point.—*Richard Wellington*.

2424. HARRIS, G. W. *Inheritance of a cheek-mole*. *Nature* 109: 78. 1922.—A man with a mole on the middle of the left cheek has 2 daughters with similar moles in almost exactly the same place. His sons do not have cheek moles but a daughter of one of them shows the trait.—*C. H. Danforth*.

2425. HARRISON, J. W. H. *Interspecific sterility*. *Nature* 110: 312. 1922.—*Salix* spp. are discussed.—*O. A. Stevens*.

2426. HAYES, H. K., AND H. D. BARKER. *The effects of self-fertilization in timothy*. *Jour. Amer. Soc. Agron.* 14: 289-293. 1922.—Self-fertilized clonal lines of timothy differed widely. This was probably due to genetic causes as there was marked correlation between the percentage of seed set under various conditions. Five out of 11 first-year, self-fertilized strains gave some albino seedlings in their progeny.—*F. M. Schertz*.

2427. HUBBS, CARL L. *Variations in the number of vertebrae and other meristic characters of fishes correlated with the temperature of water during development*. *Amer. Nat.* 56: 360-372. 1922.—This work parallels that of Johannes Schmidt [see *Bot. Absts.* 11, Entry 314]. The work of both indicates "that the meristic characters displayed by an individual fish are determined not alone by heredity, but in part also by the environmental conditions, particularly temperature, which prevail during some sensitive developmental period."—*Robert K. Nabours*.

2428. HURST, C. C. **Origin of the moss rose.** Rept. British Assoc. Adv. Sci. 1921: 453. 1921.—The rose differs from the old Cabbage Rose only in its glands, yet 12 authors give it specific rank. Sterility makes genetic investigation difficult, but bud variation seems to throw light on constitution.—*E. B. Babcock.*

2429. JACK, H. W. **Selection of coconuts.** Malayan Agric. Jour. 10: 122-127. 1922.—Selection of coconuts for planting is very desirable, as for instance among 453 12-year-old trees under observation individuals have varied in yield from 7 to 180 nuts per annum. Preliminary observations indicate that at least 10 per cent of the progeny do not come true to type. Races are characterized by the amount of copra yielded, but this falls off in age. Selection for planting by character of the nut must yield to selection by tree; and of all tall races, those with large nuts appear unacceptable, because the races possessing them produce few nuts; also races with oblong nuts seems to yield relatively less copra than medium-sized rounded nuts. But much work is needed. Whether any dwarf race can be held more desirable for planting than tall races is unsettled.—It appears that the nature of the oil varies too little between races to be worth using in selection.—*I. H. Burkill.*

2430. JACK, H. W., AND W. N. SANDS. **The dwarf coconut in Malaya.** Malayan Agric. Jour. 10: 4-12. 1922.—The dwarf coconut, or in Malay, Nyior Gading, is evidently exotic to the Malay Peninsula and may have been imported first about 30 years ago from the Netherlands Indies. It is different from the King coconut of Ceylon, which race approaches the "nyior puyoh" of the Peninsula. The authors compare "nyior gading" with the King coconut and the "Coco Mino," a dwarf coconut of the Philippine Islands. The authors look upon all these dwarfs as mutants.—"Nyior gading" contains several races distinguished by the color of the nut, 3 of which are described. "It is quite evident that natural crossing takes place between tall and dwarf races so that semi-talls . . . occur." Careful breeding experiments only can determine the relation of the factor of dwarfness to tallness; but the dwarf is said to give 80 per cent true to type in color of the nut, etc.—In an experiment with 1,270 seed-nuts, 96.2 per cent came true ivory-yellow dwarf, 68.7 per cent came green dwarf and 74.6 per cent true red dwarf, the flowers giving the nuts having been left to natural pollination.—"In the warm humid atmosphere of the lowlands of Malaya, the length of the duration of the male phase of the flowering palm is curtailed and the female phase would appear to be longer both in tall and dwarf races;" further "in Malaya the female phase not only begins, but most frequently ends before, or at the same time, as the male phase, thus rendering self-pollination the rule." The average duration of the male phase of the dwarf coconut was found to be 21 days and of the female 8 days [misprinted 3 in one place]. There are on the average 4-day intervals between the end of one phase of the tree and the beginning of the next phase, i.e., in the sequence of inflorescences. The end of the female phase in 43 inflorescences was never more than 3 days behind the end of the male phase, when pollen might still function from the dead male flowers. The pollen is wind-borne, but the authors conclude that "the flowers are as a rule self pollinated in the lowlands of Malaya." [It would appear that they mean from one flower in the inflorescence to any other as readily as to itself.]—*I. H. Burkill.*

2431. JONES, D. F. **The productiveness of single and double first generation corn hybrids.** Jour. Amer. Soc. Agron. 14: 241-252. 1922.—A general summary is presented of the relative yields of local varieties, inbred strains, single crosses and double crosses (crosses between 2 F_1 single crosses) of maize in Connecticut. With few exceptions the double crosses outyield the other classes but the fact is appreciated that the production of such seed at a cost low enough to be an important factor in corn growing remains to be demonstrated.—*J. H. Kempton.*

2432. KEITH, ARTHUR. **The stature of the Scottish people.** Nature 110: 8. 1922.—This article quotes a letter from ALEŠ HRDLÍČKA of the United States National Museum, stating that, through an error of computation, the stature of the Scottish people as given in the Final Report of the Anthropometric Committee of the British Association (1883) is too high. The corrected heights are: Scottish, 172.9 cm.; Irish, 172.6 cm.; English 171.2 cm.; Welsh, 169.4 cm.—*O. A. Stevens.*

2433. LEAKE, H. MARTIN, AND B. RAM PERSHAD. The coloration of the testa of the poppy seed (*Papaver somniferum* L.) Jour. Genetics 12: 247-249. 1922.—Three pairs of genes are stated to affect the seed color of the opium poppy. (1) *S* with *pp* causes straw color. *SS* is not markedly distinguishable from *Ss*. (2) *P* with *ss* and *bb* causes pink color, seen only in bulk. *PP* and *Pp* are indistinguishable. (3) *B* with *P* and *ss* gives blue. (4) *S* and *P* with *bb* give brown, which is with difficulty distinguished from homozygous straw; but all plants with *P* have color in the eye of the petal. (5) *SSPPBB* is deep purple, while *Ss* is gray, and the 2 intergrade. $\frac{3}{4}$ (6) Linkage is stated to occur between *S* and *B*.—John Belling.

2434. MENDIOLA, NEMESIO B. Improvement of the Lanzon (*Lansium domesticum* Jack). Philippine Agric. 11: 117-123. 1 pl. 1922.—Studies have been begun on improvement of *Lansium domesticum* by multiplication of the sweetest varieties, multiplication of varieties or bud mutations producing seedless or nearly seedless fruits, elimination of the milky juice of the rind and the bitter taste of the seed covering, elimination of the loose tissues lying at the center of the fruit between the fruit segments, and production of better-yielding strains. Six distinct types of trees are described; these differ in period required for flowering and fruiting, and in sweetness, form and size, flavor, quality, and seedlessness of fruit. Though commonly grown from seed, the tree may be propagated by marcottage, air layering, and graftage, and it is hoped that desirable forms may be preserved by these methods. Correlation between seedlessness and symmetry of fruit was determined for 478 fruits, and was found to be $+0.741 \pm 0.014$. It was found that 208 non-symmetrical fruits contained seed, 102 non-symmetrical fruits were seedless, 39 symmetrical fruits contained seed, and 129 symmetrical fruits were seedless.—Sam F. Trelease.

2435. MORGAN, THOMAS H. Some possible bearings of genetics on pathology. (Middleton Goldsmith lecture, 1922.) 33 p., 14 fig. New Era Printing Company: Lancaster, Pennsylvania, 1922.—Genetic interpretation of pathological characters, its accuracy, and possible effects are discussed. Inheritance of shortened 1st digits is cited as an illustration of dominance and of a lethal when homozygous. Hemophilia and color-blindness are cases of sex-linked inheritance. Inheritance of so-called blood groups on Mendelian assumption of 2 pairs of factors is demonstrated. Individuals belonging to same group do not agglutinate each other's blood, but corpuscles of *AA* or *Aa* individuals are agglutinated by *aa* and *BB* or *Bb* individuals by *bb*. Height or stature is probably an hereditary trait, with glandular and probably also quantitative chemical background. The author suggests caution in interpretation of feeble-mindedness as due to simple Mendelian difference. Immunity and disease are discussed with special reference to the cancer problem. Cases in higher mammals in which an induced variation is said to be inherited are of great interest to pathology. Application of genetics to pathology is pioneer work. The danger in drawing premature conclusions from insufficient evidence is pointed out.—E. E. Jones.

2436. NIKOLAWEA, A. [German rev. of: NIKOLAWEA, A. Zur Cytologie der Triticumarten. (On the cytology of Triticum-species.) Verhandl. Kongr. Pflanzenzücht.: Saratow, 1920.] Zeitschr. Indukt. Abstamm.- u. Vererb. 29: 208-209. 1922.—Chromosome counts of wheat species were made from vegetative cells. *Triticum monococcum* has 14 chromosomes; *T. durum*, *T. polonicum*, *T. turgidum*, and *T. dicoccum*, 28; *T. vulgare*, 42-44; *T. spelta*, 44; and in 1 case 50 chromosomes were counted in *T. compactum*. The cytological grouping is in accord with Tschermak's genetic classification, with Zade's serological classification, and with Vavilov's classification in respect to disease resistance.—Karl Sax.

2437. NIKOLAWEA, A. [German rev. of: NIKOLAWEA, A. Zur Kenntnis der Chromosomenzahl in der Gattung Avena. (Chromosome number in the genus Avena.) Verhandl. Kongr. Pflanzenzücht.: Saratow, 1920.] Zeitschr. Indukt. Abstamm.- u. Vererb. 29: 209-210. 1922.—*Avena brevis*, *A. strigosa*, and *A. nuda biaristata* have 14-16 chromosomes; *A. sterilis*, *A. Ludoviciana*, *A. byzantina*, 44; *A. fatua*, *A. sativa*, *A. nuda inermis*, 48; and *A. barbata*, 32. Preparations were made from root tips.—Karl Sax.

2438. PATER, B. Eine neuere Abnormität an *Digitalis purpurea* L. [A new abnormality in *Digitalis purpurea* L.] Zeitschr. Pflanzenkrankh. 32: 97-102. Fig. 1-3. 1922.—Cases of pelorism and color variation in blossoms have occurred for several years in the author's experiment plots of *Digitalis purpurea*. In 1921 an abnormal plant was found, characterized by frequent branching and erect flowers like those of *Pentstemon*, some green in color, others dark brownish red. In some blossoms the crown was split into 2 parts; others remained entire, a long green, branched shoot bearing small leaves and rudimentary blossoms developing from the center. Many cases of pelorism were also observed, all of them occurring in a plot into which plants had been transplanted, none being found in plots where plants had grown from seed. The author's observations agree with those of Peyritsch that pelorism occurs most frequently among plants subjected to a change in living conditions.—*Edith K. Cash.*

2439. PEACOCK, A. D. Pairing and parthenogenesis in saw-flies. Nature 110: 215. 1922.—Females of *Athalia liniolata* Lep. are much more abundant than males. Males of *Pristophora pallipes* Lep. are extremely rare. No males of *Allantus pallipes* Spin. have been taken or bred. When bred parthenogenetically, about 30 species produce males only; about 13, females only; about 6, both sexes. Many species are facultatively parthenogenetic. Certain species refuse to mate in captivity. *Athalia liniolata* mated and was probably polyandrous. Females of *Platycampus lucidiventris* Fall. ignore males and lay eggs parthenogenetically. Virgin females of *Phymatocera aterrima* Kl. and *Nematinus luteus* Panz. laid eggs which produced larvae and then paired with males. Varied conditions are regarded as of value in regulating sex ratio.—*P. W. Whiting.*

2440. PUNNETT, R. C. On a case of patching in the flower colour of the sweet pea (*Lathyrus odoratus*). Jour. Genetics 12: 255-281. 1 pl., 3 fig. 1922.—The author gives the genetical behavior of patching in the flower color of the sweet pea. Plants or shoots, bearing these patched or mosaic flowers, are affected in habit of growth, being less luxuriant than normals. All tested plants, showing mosaic flowers, were found to be heterozygous, producing normal, patched, and red flowers in varying proportions. Since expected Mendelian ratios did not occur, the inheritance of patching in the sweet pea was thought to be possibly analogous to reported cases of flaking in *Mirabilis* and *Primula*, variegation in maize, and striping in *Antirrhinum*. Hypothetical explanations are given as to why irregular segregations occurred.—*Richard Wellington.*

2441. RIS, VICTOR. Some notes on rubber estates of the future. Malayan Agric. Jour. 10: 112-117. 1922.—A paper in the Archief voor de Rubberecultuur is reprinted indicating the great importance of selection work in the present competition for existence between rubber plantations.—*I. H. Burkill.*

2442. ROBERTS, H. F. A new method of corn improvement by selection. Sci. Agric. 3: 37-50. 1922.—Following an extensive review of the literature on the subject of selection in maize the author proposes 3 methods of breeding corn: 1 adapted for experiment stations, 1 for commercial breeders, and the 3rd for the farmer. These systems all involve various modifications of the ear-to-row method. The effect of selection of various plant and ear characters on yield of grain is summarized and a comprehensive bibliography is appended.—*J. H. Kempton.*

2443. SALAMAN, REDCLIFFEN. The inheritance of fur types and hair characters in rabbits. Jour. Genetics 12: 179-207. 24 fig. 1922.—Following on research of inheritance of human hair shape, the author investigated a series of rabbit skins lent him by C. C. Hurst, upon which the latter founded his research on the heredity of coat characters [HURST, C. C. Experimental studies in heredity in rabbits. Jour. Linn. Soc. Zool. 29: 233. 1905]. There are 2 distinct types of fur in the rabbit, designated in this paper as "A" and "B" types. "A" is common to the wild and all short-coated rabbits, and in addition it is found in some Angoras. There is no correlation between either of the 2 types and coat color or other distinctive patterns

recognized by the fancier or with sex. "B" is a type exclusively found in some long-coated rabbits. There are 3 shapes common to the transverse sections of the Small-hair at the skin level, square, round, and oval. The square type is recessive and can occur pure, the round type is dominant to the square and was found pure only in relation to "B" type pelts; the oval is the form most in evidence in the wild rabbit, and is the normal dominant form in short-coats. In certain rabbits exhibiting the Dutch marking, transverse sections of the Small-hairs in the white areas are found to be of a square shape, and those in the dark of a round or oval shape. This condition is to be found on both short- and long-coated Dutch marked animals. In 1 instance where the Dutch pattern was developed in an animal, heterozygous for square and round hair section, as well as "A"- and "B"- pelt types, a differentiation took place so that the white area presented entirely different hair characters from that existing in the dark portion. The differentiating factor, whether heterozygous or otherwise, is able to influence the hair shapes much more completely in an animal which is pure for the Dutch pattern factor than in one which is heterozygous and which exhibits the presence of the factor only by the "marking" on the shoulder. The suggestion is made that the extreme looseness and elasticity of the ordinary rabbit pelt in life is associated with the physiological requirements of the hair follicles, which at certain recurrent phases of the coat's growth, must accommodate hairs the transverse area of which is as much as tenfold that of the same when fully grown.—*Redcliffe N. Salaman.*

2444. SANDO, C. E., AND H. H. BARTLETT. **Pigments of the Mendelian color types in maize: isoquercitrin from brown-husked maize.** Jour. Biol. Chem. 54: 629-645. 1922.—The chemical nature of plant colors is discussed and the desirability of correlating chemical compounds with genetic factors is pointed out. For this purpose color types of maize have been chosen and a brief description of the interaction of 3 plant color factors, *A*, *B*, and *Pl*, proposed by Emerson, is given. A flavonal glucoside known as isoquercitrin has been isolated from the husks of Emerson's brown type of maize having the factorial composition *aa*, *BB*, *Pl Pl*. This glucoside is identical with that originally found by Perkins in cotton flowers and probably also with a similar substance derived by Heyl from the pollen of ragweed. The relatively large yield of this glucoside from maize has made it possible to add to the characterization of isoquercitrin by Perkins and the methods by which it was extracted and identified are given in detail.—*J. H. Kempton.*

2445. SCHEGALOW, S. [German rev. of: SCHEGALOW, S. **Das Erscheinen des Gigantismus beim Hafer.** (The appearance of gigantism in oats.) Verhandl. Kongr. Pflanzenzücht.: Saratow, 1920.] Zeitschr. Indukt. Abstamm.- u. Vererb. 29: 207-208. 1922.—Gigas types of individuals were found in a selection of *Avena orientalis*. They constituted about 25 per cent of the progeny of 1 selection and bred true in later generations. The gigas type was relatively sterile and under usual conditions matured very late. The chromosome number was found to be the same as for the normal form.—*Karl Sax.*

2446. SCHMIDT, JOHS. **Diallel crossings with the domestic fowl.** Jour. Genetics 12: 241-245. 1922.—Two cocks, X and Y, of mixed breeding were each mated with the same 5 hens, a, b, d, e, and f, and 5 progeny from each mating—making a total of 50 chickens—were studied. The number of vertebrae in each individual was counted. The average number of vertebrae in the 25 daughters of each cock is called his "generative value" and the actual number of vertebrae in his body, his "personal value." The same application is made to the hens.—*F. A. Hays.*

2447. SHULL, G. H. **Über die Heterozygotie mit Rücksicht auf den praktischen Züchtungserfolg.** [On heterozygosis with emphasis on the practical breeding results.] Beitr. Pflanzenzücht 5: 134-152. 9 fig. 1922.—Self-fertilized strains of maize when crossed gave increases in yield of grain of 380 per cent above the inbred parents in the 1st generation, 41 per cent in the 2nd, and 27.4 per cent in the 3rd. The best *F*₁ crosses exceeded the original cross-pollinated variety by 20 per cent. The coefficient of variability of the inbred strains

was 9.08 per cent, for F_1 , 9.06 per cent, and for F_2 , 12.63 per cent. The increase in size and vigor resulting from crossing is called heterosis and is interpreted as due to a stimulation accompanying heterozygosis. While selection of the best individuals for breeding purposes in self-fertilized, homozygous plants is justified, on account of heterosis the best individuals in cross-fertilized plants and in animals are not the ones which always give the best results. [A discussion follows on pages 152-158.]—D. F. Jones.

2448. SMITH, LOREN B. **Breeding mosaic resistant spinach and notes on malnutrition.** Virginia Truck Exp. Sta. Bull. 31/32. 138-160. 1920.—The author discusses chiefly methods used in the development of the Virginia Savoy, a mosaic-resistant spinach. The resistance factor was obtained from a variety of spinach known as Manchuria obtained by the late Frank M. Meyer, near Liaoyang, Manchuria. The latter variety furnished the female and the varieties Round Thick-leaf Winter, Bloomsdale Savoy, Long Standing, and Viroflay the male parentage of the best strains of the Virginia Savoy. "The hybrids after several years of field selection and roguing, gradually developed a fairly uniform type and a high degree of mosaic resistance." In selecting desirable strains the characters taken into consideration were (1) resistance to mosaic, (2) size of plant, (3) savoying, (4) color, (5) thickness of leaves, (6) closeness, (7) shape of leaves, (8) long standing qualities, (9) type of growth, (10) number of shoots at crown, and (11) color of petioles. Besides being resistant to mosaic, the Virginia Savoy is less attractive to aphids than other commercial varieties. In Feb. 1918, field counts showed 3.2 per cent of commercial Savoy plants uninfested while 69.1 per cent of the Virginia Savoy plants were uninfested. This was found to hold true repeatedly under greenhouse, field cage, and field conditions. The author states, however, that "during the periods favorable for the development of aphids the Virginia Savoy stocks may become as heavily infested as other varieties." By rigid selection of stocks the mosaic was decreased from 6.14 per cent in the F_2 Manchuria-Savoy hybrid generation to 0.64 per cent in the F_3 generation. "The Virginia Savoy variety compares favorably with the commercial strains in the production of marketable spinach. In 1918 the former yielded 146 barrels and the latter 135 barrels per acre."—H. A. Jones.

2449. SPRAGUE, T. A. **Meristic variation in *Papaver dubium*.** Jour. Bot. 60: 299-300. 1922.—Variation is noted in the number of stigma-rays. Poorly nourished plants have fewer and well nourished more rays than the average. A positive correlation was observed between number of flowers per plant and number of stigma-rays per flower.—J. L. Collins.

2450. STOUT, A. B. **Preliminary report of investigations with species of *Lilium*.** Jour. New York Bot. Gard. 23: 155-158. 1922.—Over 30 species of lilies have been studied. Lack or irregularity of seed production in these *Liliums* was shown to be due mainly to self or cross incompatibility. Varieties from China are being crossed with cultivated strains of the same species to test for cross compatibility. Several species of *Lilium* native to the U. S. A. have been successfully crossed. The chief aims of the work are to determine cultural requirements; and to study self and cross compatibility, the limits of hybridization, and the natural relationships of the varieties and species.—John Belling.

2451. SÜFFERT, F. [German rev. of: KNOLL, FRITZ. **Insekten und Blumen. Experimentelle Arbeiten zur Vertiefung unserer Kenntnisse über die Wechselbeziehungen zwischen Pflanzen und Tieren. (Insects and flowers. Experimental work to enlarge our knowledge of the mutual relations between plants and animals.)** Abhandl. Zool.-Bot. Ges. Wien 12: 119 p. 1921.] Zeitschr. Indukt. Abstamm. -u. Vererb. 29: 202-207. 1922.—As the elements in flower biology K. Chr. Sprengel has listed the sexual apparatus, nectar, corolla color, and fragrance; of these Knoll investigated place of corolla color and fragrance in insect attraction. He used *Bombylius fuliginosus* (bee-fly) and *Muscari racemosum* (grape hyacinth), the latter having a spike of sterile, closed, and odorless flowers at top and fertile, fragrant flowers with nectar below. Evidence from work on distribution of odor, separation of odor from color stimuli, neutralization of color, blue and gray papers indicate reaction of insect to hue and

not to brightness value or odor, at a distance. After insect has approached blossom, odor is responsible for attachment to it. Further work indicates positive reaction of *Bombylius fuliginosus* to blue and disregard of yellow flowers even though they contain nectar, except after the *Muscari racemosum* season is over. *Bombylius medius*, which uses pollen as well as nectar, reacts positively to yellow flowers. *B. fulvescens*, which like *B. fuliginosus* uses only nectar, reacts only to blue flowers. Where *B. fuliginosus* occurs all flowers offering nothing to it are yellow and this may account for connection with non-yellow flowers.—Süffert suggests possibility of inherited reaction here, though acquirement of relationship between insect and flower is not excluded. He considers the importance of researches of this kind to consist in the analysis of specific cases of adaptation, and commends the author's efforts to set forth purely objectively what has hitherto been under the cloud of teleological and "purposeful" speculations.—Helen D. Hill.

2452. SUMNER, FRANCIS B., MARY E. McDANIEL, AND RALPH R. HUESTIS. A study of influences which may affect the sex-ratio of the deer mouse (*Peromyscus*). Biol. Bull. 43: 123-165. 7 fig. 1922.—Data are based on over 4,600 deer mice of known sex, born and raised in captivity, under temperature conditions approximating those existing in nature. Litter size 1 to 9, mean of 1,567 litters, is 3.22. Sex ratio for the whole population is 97.37 ± 1.93 . When only litters in which no deaths are known to have occurred are included, the sex ratio becomes 98.01 ± 2.07 . Litters known to have been incomplete give a ratio of 93.08 ± 5.25 . To eliminate the effect of seasonal differences, the mean of the monthly means was computed and found to be 95.65. The authors state that none of these figures differs significantly. Probable errors in this paper were based on a formula giving about twice as great errors as that employed by previous writers, and the probabilities claimed by the authors are correspondingly lower. A definite seasonal cycle seems to exist in the proportion of males to females born. Two annual maxima occur, in Mar.-Apr. and Aug.-Oct.; the lowest ratio is 78.79 ± 6.93 in Nov., the highest 113.04 ± 8.04 in Apr. This difference is $3\frac{1}{2}$ times the probable error and would ordinarily be considered significant. But when the material is subdivided differently the results are in some cases contradictory and the authors do not regard the existence of seasonal cycle in sex ratio to be proved conclusively by their data. "Subspecific" hybrids (1,722) give mean ratio of 104.76 ± 3.41 . Mice of "pure" race (2,930) give mean ratio of 93.27 ± 2.32 . Positive correlation exists in this material between size of litter and sex ratio. Litters of 1-3 give mean ratio of 94.85 ± 2.94 , those of 4-9 give mean ratio of 102.42 ± 3.01 . Size of probable errors raises question as to significance of this correlation, however. No preponderant tendency toward production of homosexual litters was found, thus no likelihood that polyembryony is at all common. Sex ratio is lower for earlier litters (91.7) than for later ones from the same mother (103.3); numbers are small, however, inbreeding and outbreeding seem to have had no effect. Negative results were obtained from comparison of offspring of meat-fed individuals with offspring of individuals with strictly vegetarian diet; numbers here were also small. The most significant result, statistically speaking, is the fact that sex ratios for the 7 different years included in the records show wide variation, ranging from 125.36 ± 7.82 in 1916 to 70.56 ± 4.70 in 1917. This difference is not due to seasonal distribution of births, nor to preponderance of hybrid births, nor to operation of any other recognized factors.—E. E. Jones.

2453. TSCHERMAK, E. [Rev. of: (1) BAUR, E. Die wissenschaftlichen Grundlagen der Pflanzenzüchtung. Ein Lehrbuch für Landwirte, Gärtner und Forstleute. (The principles of plant breeding. A textbook for agriculturists, gardeners and foresters.) v + 120 p., 6 pl., 11 fig. Gebrüder Borntraeger: Berlin, 1921 (see Bot. Absts. 12, Entry 1034). (2) FRUWIRTH, C., und TH. ROEMER. Einführung in die landwirtschaftliche Pflanzenzüchtung. (Introduction to agricultural plant breeding.) 150 p., 4 pl., 27 fig. Paul Parey: Berlin, 1921.] Wiener Landw. Zeitg. 72: 1922.—The first book is to be recommended for the progressive farmer or gardener who wishes to know the essentials of the theory and practice of plant breeding; the 2nd serves a very useful purpose in providing instructors of plant breeding with an inexpensive text which is more suitable for general students than Fruwirth's Handbook of Agricultural Plant Breeding. [See also Bot. Absts. 11, Entry 2472; 12, Entry 1784.]—F. Weiss.

2454. TORNAU. Die Züchtung des Göttinger Roggens. [The breeding of Göttinger rye.] Jour. Landw. 70: 171-190. 1922.—Selections of 3 lines of Göttinger rye grown for 10 years and 1 pure line grown for 6 years show no decreased yield due to inbreeding. It is shown by statistical methods that inbreeding did not change the relation of various morphological characters.—Karl Sax.

2455. UPHOF, J. C. TH. Eine polymorphe F_1 -Generation aus der Kreuzung von *Phaseolus vulgaris* und *Phaseolus multiflorus*. [A polymorphous F_1 generation from crossing *P. vulgaris* and *P. multiflorus*.] Zeitschr. Indukt. Abstamm.- u. Vererb. 29: 186-192. 1922.—In crosses of varieties of *Phaseolus vulgaris* \times *P. multiflorus* F_1 plants were obtained which differed greatly in size, leaf shape, and size of seed. The F_1 flower color and seed color was like that of the male parent.—Karl Sax.

2456. WARREN, ERNEST. A preliminary account of an interspecific hybrid and backcrosses of *Digitalis*. South African Jour. Sci. 18: 359-373. Pl. 4-5. 1922.—Results are recorded of hybrids between *D. gloxiniaeflora* and *D. lutea* and also of backcrosses of the hybrid with the parent species. Crossing the 2 species was found to be more difficult when *D. lutea* was used as the seed plant instead of *D. gloxiniaeflora*. The hybrids resembled *D. gloxiniaeflora* more closely than *D. lutea* in general appearance, in relative width of leaf, length and breadth of flowers, and ratio of these dimensions.—The data obtained from backcrosses of the hybrids with both parents is tabulated. In the characters measured, the factors appear to blend on crossing rather than to remain unchanged. "In all the measurable characters examined there was no clear reappearance in the backcrosses of the grandparental characters in an uncontaminated condition. The view that these results are due in every case to the existence of multiple, independent, unchangeable factors would be only justified if the backcross offspring exhibited exceptional variability, but such is not the case. Thus the results obtained with interspecific hybrids resemble those found with intervarietal hybrids." [See also following entry].—Edith K. Cash.

2457. WARREN, ERNEST. Inheritance in the foxglove, and the result of selective breeding. Biometrika 14: 103-126. Pl. 1. 1922.—Additional data on crossing *Digitalis gloxiniaeflora* are recorded in continuation of experiments previously reported [see preceding entry]. The author concludes that "the mode of inheritance is Mendelian with reference to the qualities peloric and non-peloric, purple and white corolla, purple spots and brown spots. If, however, there are any marked differences in the intensities of these qualities, the mode of inheritance of the intensity of the quality was found to be of the blended type. The other characters examined were quantitative in nature, such as degree of the development of purple spots and the ratio of breadth to length of corolla, and these characters blended completely. The evidence of the present investigation is therefore definitely against any general application of the theory of pure-lines and of genotypes of any appreciable magnitude, and further it indicates that selective breeding within self-fertilised generations of a homogeneous race is capable of modifying that race to a marked degree."—Edith K. Cash.

2458. WINGE, Ø. One-sided masculine and sex-linked inheritance in *Lebister reticulatus*. Jour. Genetics 12: 145-162. 2 pl. 1922.—The secondary sex-characters in *Lebistes* are inherited as either one-sided masculine with the X-chromosomes empty, or as a one-sided masculine and sex-linked combination with the X-chromosome containing factors for color. "The whole mode of inheritance is sex-limited to the male individuals, as the factors are found cryptomerically in the females." The condition is the opposite of that in *Drosophila* as the Y-chromosome carries color factors in all the races examined. The principle difference between the X- and Y-chromosomes is that the male sex is represented by a dominant factor in the latter and the female sex by the allelomorphic factor in the former. Crossing over appears to occur rarely between the X- and Y-chromosomes. The females have 44 + X + X chromosomes and the males 44 + X + Y. The genotype of each male may be determined by observation of the color effects. The females all present the same appearance.—Robert K. Nabours.

2459. WOODWORTH, C. M. **The extent of natural cross-pollination in soybeans.** Jour. Amer. Soc. Agron. 14: 278-283. 1922.—Natural hybrids are shown to occur in the soybean. In a total of 205 seed from recessive white-flowered plants, none proved to be hybrid. When cotyledon color was used as an index of hybridity, only 3 pods in a total of 7,480 contained hybrid seed. If all of the ways in which crossing may occur are taken into account the proportion would be 1 hybrid pod in 625, or 0.16 per cent. The variety, locality, and season will cause the percentage of cross pollination to vary. Hybrids may also arise by mutation.—*F. M. Schertz.*

HORTICULTURE

FRUITS AND GENERAL HORTICULTURE

2460. ANONYMOUS. **Fruit-growing and research.** Nature 110: 497. 1922.

2461. ANONYMOUS. **The 1922 fruit crop.** Jour. Dept. Agric. Ireland 22: 285-286. 1922.—The general effects of weather, insects, and diseases on apples, pears, and other fruits are noted.—*Donald Folsom.*

2462. ANDREWS, J. W. **Refrigeration and pre-cooling of citrus fruit.** Proc. Florida State Hort. Soc. 35: 59-62. 1922.—This is a report on experiments in pre-cooling oranges in Florida. Under the most favorable conditions it requires 6 hours to cool the fruits in a single box from 85 to 40°F., and to this 1 hour must be added if the "wad pack" is used. If a large number of boxes are stacked in a typical pre-cooling room it requires 3-4 times as long. A study of individual car records indicate that under ordinary conditions icing in transit is not necessary.—*J. C. Th. Uphof.*

2463. BARTLETT, R. G. **The cultivation of ginger.** Agric. Gaz. New South Wales 33: 818. 1922.—Two-eyed sets are planted in 2-foot drills 9 inches apart to a depth of 3 inches in manured soil. The crop is harvested in the flowering stage and yields 2-4 tons per acre.—*L. R. Waldron.*

2464. BARTLETT, R. G. **The manuring of bananas.** Agric. Gaz. New South Wales 33: 830-832. 1922.—The importance of humus and the value and kinds of cover crops are discussed. Two fertilizers rich in potash are suggested.—*L. R. Waldron.*

2465. BECKWITH, CHARLES S. **August flooding for cranberry girdler.** Proc. Amer. Cranberry Growers' Assoc. Proc. Ann. Conv. 53: [Pages unnumbered.] 1922.—Damage in New Jersey by cranberry girdlers was increasingly severe in 1921-1922. Flooding the bogs for 24 hours in early August causes the girdlers to float ashore where they are destroyed by predaceous insects. (Girdlers submerged in cheese cloth bags were killed in 24 hours.) This resulted in lessened infestation the succeeding year. Flooding in August is dangerous and should be used only as a last resort in serious infestations.—*J. K. Shaw.*

2466. BIOLETTI, FREDERIC T. **Pruning young olive trees.** California Agric. Exp. Sta. Bull. 348. 87-110. 1922.—Pruning retards the growth of olive trees, especially when young. The excessive pruning often practiced on young trees may retard development 90 per cent. Mission olives which receive no pruning during the first 4-5 years develop a more perfect form than pruned trees. The method of handling young Mission olives recommended on the basis of 5 years' experiments hastens development, improves form, promotes early bearing, and saves the whole expense of pruning for 4-5 years. The method is probably applicable to any

varieties of naturally upright habit. The use of stakes and tying may be required during the first 2-3 years with varieties of spreading habit like the Manzanillo and Ascolano. This expense would be offset by the saving in pruning and the improved form of the tree; and the more rapid development would be a net gain.—*A. R. C. Haas*.

2467. BIOLETTI, FREDERIC T. **Supports for vines.** California Agric. Exp. Sta. Circ. 252. 19 p. 1922.—The methods described in this circular are suited to nearly all the varieties and conditions of the grape-growing districts in California. In the 1st method the head-pruned vines require only temporary supports; under most favorable conditions the stake may be removed in 2-4 years. The stakes are joined by fencing wire. The 2nd method is used when weeds make cross-cultivation necessary; here the wire is omitted. The 3rd method is for cane-pruned vines which require permanent supports for the annually renewed fruit canes, and consists of a trellis made of pickets and 2 wires. The 4th method is a modification of the 3rd. Directions are given in regard to the heights of stakes and wires, the number of wires, the time of placing supports, support alignment, and the length of trellises, together with kinds and cost of materials and the labor costs.—*A. R. C. Haas*.

2468. BIOLETTI, FREDERIC T. **Vineyard plans.** California Agric. Exp. Sta. Circ. 253. 12 p. 1922.—Directions are given covering the planting and irrigation of vineyards.—*A. R. C. Haas*.

2469. DARNELL-SMITH, G. P. **The effect of blood manures on citrus.** Agric. Gaz. New South Wales 33: 823. 1922.—It is not evident from experiments that injurious results follow application of blood manures to citrus fruits other than are brought about purely by the excessive application of nitrogen contained in the fertilizer. Blood manures did not increase die-back.—*L. R. Waldron*.

2470. DEARING, CHAS. **Grape growing in Florida.** Proc. Florida State Hort. Soc. 35: 121-126. 1922.—The European grape (*Vitis vinifera*) is of little importance in Florida and commercial plantings are not recommended. In northern Florida the Muscadine grape is promising as a commercial venture.—*J. C. Th. Uphof*.

2471. KOCH, RICHARD. **Die Einführung der helländischen versteigerung in Straelen, Crefeld, Schierstein, Ocholt usw.** [The introduction of Dutch auctioning in Straelen, Crefeld Schierstein, Ocholt, etc.] Gartenwelt 26: 509-511. 1 fig. 1922.—It is emphasized that Dutch auctioning of fruits and vegetables should be introduced into Germany. The electric selling apparatus as generally used in Holland and in a few places in Germany is described and its good points discussed.—*J. C. Th. Uphof*.

2472. KURT, MEYMUND. **Unsere Baumschulen, ihr rascher Aufstieg und ihr heutige Bedeutung.** [Our nurseries, their rapid development and present significance.] Gartenwelt 26: 457-459. 1922.—A general description is given of the development and importance of German nurseries where trees and shrubs are grown. In 1870-71 the only firms of importance were those in France, Belgium, and Holland. German nurserymen who had worked abroad adapted the foreign methods to their conditions and at present there are 1,600-1,800 such nurseries in Germany with about 15,000 persons employed.—*J. C. Th. Uphof*.

2473. LEONARD, GEORGE V. **Grove factors influencing citrus fruit quality.** Proc. Florida State Hort. Soc. 35: 21-24. 1922.—Oranges are grown in all sections of Florida but the rather heavy, stony soils give the best quality of fruit. The sour orange [*Citrus aurantium*] is preferred as a root stock for most conditions, but on the ridge land of the lower East Coast in Polk County, the Rough lemon stock gave good results. There was an indication that the fruit dried out at the stem end when Valencias were budded on lemon stock. Varieties, tillage, fertilizers, spraying, and pruning are also discussed.—*J. C. Th. Uphof*.

2474. LIEMS, J. A. **De Sinaasappelcultuur.** [Orange growing.] *West-Indië* 7: 3-11. 1922.—In Surinam, of all tropical fruits, the orange is best suited for export. It ripens July-Oct. when no other oranges are on the European markets. Sand is better than clay for its culture. Lime [*Citrus aurantifolia*] and lemon seedlings are recommended for stocks. The following varieties are recommended: Groningen, a native variety, Washington Naval, and Lambs Summer. Some good native sorts are also worthy of further observation.—*J. C. Th. Uphof.*

2475. LIEMS, J. A. **Proefneming met sinaasappel op lemmetje onderstam.** [Experiments of oranges on lime stock.] *West Indië* 7: 12-14. 1922.—On account of the warm, moist climate the humus supply soon disappears from the highland soils after timber is removed. On such soils the lime [*Citrus aurantifolia*] has proved a better stock for orange than orange seedlings.—*J. C. Th. Uphof.*

2476. MILSUM, J. N. **The Brazil-nut in Malaya.** *Malayan Agric. Jour.* 10: 87-88. 1922.—At Kuala Lumpur the Brazil-nut (*Bertholletia*) has set fruit when 9 years old. Propagation by cuttings and layers has not been found possible.—*I. H. Burkill.*

2477. MORLEY, JOHN. **Avocados on high pine land.** *Proc. Florida State Hort. Soc.* 35: 42-45. 1922.—It was observed that on high pine land the avocado trees developed more short fruiting branches than those grown on muck soils. Planting and fertilizing are discussed. Careful shading was adopted and frequent watering of the grove practiced. Mulching was followed at first but later abandoned for cultivation. The varieties grown are Trapp and Pollock.—*J. C. Th. Uphof.*

2478. POPENOE, WILSON. **Avocado explorations in tropical America.** *Proc. Florida State Hort. Soc.* 34: 31-36. 1922.—This article describes the 3rd avocado expedition to South and Central America. A wild form was discovered on the slopes of the Irazu volcano in Costa Rica which may be the prototype of the cultivated varieties of West India and Guatemala. It may prove to be of value as a stock on which to work some of the more delicate varieties and for use in breeding. The wild avocado (*aguacate de anís*) grows in small ravines and on moist slopes at an elevation of 400-600 feet. The wild avocados of Santa Marta, Columbia, are of the West India race and have escaped from cultivation. Some valuable cultivated varieties of the Mexican race were found in Ibarra, northern Ecuador. They are larger than any variety in Mexico or California and came from the valley of the Rio Chora where several thousand avocado trees are grown. The most promising variety introduced into the U. S. A. weighs 18 ounces, has small seeds, and flesh free from fiber. It was named for an Ecuadoran Tamayo. [See also *Bot. Absts.* 11, Entry 4026].—*J. C. Th. Uphof.*

2479. SANDS, W. N. **The cinchona (quinine) industry in Java.** *Malayan Agric. Jour.* 10: 65-86. 1922.—A report upon the various phases of cinchona cultivation in Java is presented.—*I. H. Burkill.*

2480. SAX, KARL, AND JOHN W. GOWEN. **The relation of tree type to productivity in the apple.** *Maine Agric. Exp. Sta. Bull.* 305. 20 p., 4 fig. 1922.—In 1 Ben Davis orchard of 881 trees, productiveness is associated with large size and great number of laterals while unproductiveness is associated with small size and upright spurless branches. Differences in productivity are attributed to differences in soil and root stocks rather than to scions. It is recommended that root stocks for new orchards be from rapidly growing 1-year old stock.—*Donald Folsom.*

2481. STODDART, J. **Grading and sizing of apples.** *Jour. Ministry Agric. Great Britain* 29: 543-545. 1922.—An improved type of handsizer for apples is described and illustrated.—*M. B. McKay.*

2482. TUFTS, WARREN P., AND GUY L. PHILIP. **Almond pollination.** California Agric. Exp. Sta. Bull. 346. 3-35. 1922.—Almond varieties may be roughly divided into 2 classes, early bloomers and late bloomers, when the length of effective full bloom is considered. The 1st blossoms produced by most almond varieties yield a smaller amount of pollen, which is also inferior in viability to that produced by flowers on the same tree maturing several days or a week later. Pollinizing agencies, such as the honey bee, are necessary to the set of a good crop of fruit. One colony of honey bees should be provided for each acre of orchard. All almond varieties thus far tested have proved self-sterile, at least in certain years. The I. X. L. and Nonpareil varieties proved practically inter-sterile during 3 seasons' work. The Languedoc and Texas proved practically inter-sterile in 1917 and 1919. The California, disregarding its own commercial value, seems to be the best pollinizer for all varieties thus far tested which have a coincident period of bloom. Data on successful inter-varietal pollinations are given for many varieties. Care should be taken in the arrangement of varieties in the orchard to facilitate cross-pollination and convenience in harvesting.—A. R. C. Haas.

2483. VAILE, R. S. **Fertilizer experiments with citrus trees.** California Agric. Exp. Sta. Bull. 345. 466-512. 1922.—There is a positive value to be derived from fertilizing citrus trees on any of the soils involved in these trials, as measured by increased crop yields. The chief response is obtained from nitrogen, none following the use of potash or phosphoric acid in any of the trials reported, either when used alone or in conjunction with nitrogen. Lime, applied as ground limestone, has not been of value in the trials reported except at Chula Vista on the Kimball sandy loam soil. Bulky organic material has been of importance in citrus fertilization. Specific fertilizing materials have given different results in different locations, so much so that findings from one set of field trials should not be too literally interpreted for any other set of conditions. Field trials and orchard surveys indicate clearly that fertilization is required for the economical production of citrus fruits under usual southern California conditions. It appears that fertilizing is often delayed too long after planting and that larger applications might be used with profit. Neglected groves may be improved by the use of nitrogenous fertilizers. Typical mottle leaf and attendant characteristics are not improved by the use of commercial fertilizers, particularly inorganic forms. Covering the ground with straw mulch, thus eliminating the necessity for tillage, improves run-down citrus groves. This method of culture is likely to be limited in effectiveness to a period of 2-3 years, following which ordinary tillage should again be resorted to. The use of green-manure crops in winter has been followed by conflicting results in the different trials.—A. R. C. Haas.

FLORICULTURE AND ORNAMENTAL HORTICULTURE

2484. ANONYMOUS. **A national arboretum and garden in Washington.** Wild Flower Preservation Soc. [Washington, D. C.] Circ. 5. 4 p. 1923.—This circular sets forth the desirability of securing a tract of 800, which in the future could be increased to 2000, acres along the Anacostia River at the northerly end of Maryland avenue, 2 miles from the Capitol. This tract of land would be used as a site for a national arboretum and the Washington Botanical Garden would be moved there from its present location.—C. G. Vinson.

2485. BENEDICT, R. C. **Ferns as house plants.** Amer. Fern Jour. 12: 77-92. Pl. 5-7. 1922.—The author discusses the care of ferns in the home and the best kinds for that use. The "florist divides cultivated plants" into "four classes according to temperature requirements,"—"hardy," "semi-hardy," "greenhouse," and "stove." The semi-hardy or greenhouse types are the only ones suited for house use. Five semi-hardy and 24 sub-tropical varieties are described and most of them are illustrated by photographs.—F. C. Anderson.

2486. BLITTERA, NIKOLAUS. **Beiträge zum Anbau und Auslese des Mohns.** [Investigations in cultivation and selection of poppies.] Wien. Landw. Zeitg. 72: 44-45. 1922.—Planting distance, both as between plants and rows, influences the number of capsules borne per plant, the ratio of seed weight to capsule weight, and to some extent the form of capsule. The most suitable planting distance varies among different strains. Normal capsule shape is spherical

or somewhat oblate; in cultivation pear-shaped capsules also appear. The latter show the most favorable proportion of seed weight to capsule weight and selection should seek to preserve this form. Capsules of average size rather than the largest ones show the highest seed weight in proportion to weight of capsule. Similarly capsules of light color—brown or yellowish—have a higher proportionate seed weight than the violet brown ones.—Precocious germination of seed within the capsule sometimes occurs during prolonged rainy weather. Violet-brown capsules show the most rapid water absorption and most tenacious retention, hence premature germination occurs most frequently in capsules of this color. Capsules of average size, pyriform in shape and light brown in color, should be selected.—*F. Weiss.*

2487. CLARKSON, EDWARD H. **Experiments in naturalizing ferns.** *Amer. Fern Jour.* 12: 19-22. 1922.—The article describes the transplanting of several species of ferns, giving situations where planted and results after 6 years. In most cases the ferns have done well.—*F. C. Anderson.*

2488. LOBNER, M. **Pfitzers Gladiolen Neuheiten.** [Pfitzer's gladiola novelties.] *Möllers Deutsch. Gärt. Zeitg.* 37: 256. 1922.—Herbstzauber flowers late and develops very large, salmon-red flowers. This variety is promising. *Weisser Samling* (No. 12,498), or *Magnolia*, has a growth similar to the former sort with pure white flowers.—*J. C. Th. Uphof.*

2489. UPHOF, J. C. TH. **Das Aushöhlen der Zwiebeln bei der Vermehrung der Hyazinthen.** [Scooping of bulbs in the propagation of hyacinths.] *Möller's Deutsch. Gärt. Zeitg.* 37: 277-278. 1 fig. 1922.—This procedure is practiced in Holland, a special knife being used. Depending on the variety, the axis of the bulb is scooped out to as near the scales as possible or a cross is cut out, the bulbs being then placed upside down in boxes. The wounds are disinfected with a solution of mercuric chloride or with lime, although the latter is less effective. Later the bulbs are laid on wooden ridges in the dark at a temperature of 15-20°C. in rooms constructed for the purpose. They remain in this situation until about 2 weeks before planting, when they are slowly accustomed to daylight. They are then (Oct.-Dec.) planted upside down in the field and during the summer young bulbs develop in the old ones. The crop is harvested in July and the young bulbs replanted the following autumn, flowering in the 2nd or 3rd year.—*J. C. Th. Uphof.*

VEGETABLE CULTURE

2490. GEISE, FRED W. **Storing and bedding sweet potato stock.** *Virginia Truck Exp. Sta. Bull.* 39/40. 223-234. 1922.—The author discusses principles involved and methods of handling in the field and storage to obtain the highest quality sweet potato seed stock. Harvesting, selection, storage, disinfection, beds, bedding, and care of the beds are given consideration.—*H. A. Jones.*

2491. KREUZPOINTER, J. **Asparagus zur Schnittgrüengewinnung.** [Asparagus for cutting bouquet-green.] *Möller's Deutsch. Gärt. Zeitg.* 37: 253-254. 1922.—*Asparagus retroflexus arboreus* and *A. Sieberianus* are recommended for use in bouquets. The latter can be propagated from cuttings, 30-40 per cent rooting when taken in spring or summer.—*J. C. Th. Uphof.*

2492. MAGOON, C. A., AND C. W. CULPEPPER. **A study of sweet-potato varieties, with special reference to their canning qualities.** *U. S. Dept. Agric. Bull.* 1041. 34 p., 3 pl. 1922.—Forty-four varieties of sweet potatoes, here described in some detail and illustrated by color plates, were tested for canning qualities. At Arlington, Virginia, Gold Skin ranked 1st for quality of product for 2 seasons. Yellow Jersey, Early Red Carolina, and Big Stem Jersey represent the best of the dry firm types; Dooley, Porto Rico, Nancy Hall, Mullihan, and Vineless Pumpkin "yam" are good varieties of the deep colored group; and the Belmont, Miles, and Yellow Strasburg are good varieties of the lighter fleshed medium-moist type. Qualities to be considered in canning are discussed for the various varieties, also the changes after digging and the chemical changes of the product. Effect of oxygen on product, temperatures

for canning, time required, etc., are given. Potatoes which are firm after cooking contain high percentage of starch, while those which become soft have a high percentage of dextrin and low percentage of starch. Changes in plasticity are due to transformations affecting ratio of starch to moisture.—*J. T. Buchholz.*

2493. NICOLAISEN, N. *Unsere Gemüsebauversuchsfelder.* [Experimental fields for vegetables.] *Gartenwelt* 26: 520–521. 3 fig. 1922.—This article outlines experimental work with vegetable crops. The types of investigations and functions stressed are: (1) adaptation of vegetables for certain uses; (2) distance for planting and best kinds of culture, proper amount of seed per unit of area, secondary crops, comparative use of machinery and hand labor; (3) fertilizer experiments; (4) studies of fungicides and insecticides; (5) testing of novelties; (6) encouragement of vegetable forcing; (7) stimulation of the use of vegetables by conducting courses in cooking; (8) acquaintance with the needs of the trade; (9) dissemination of information.—*J. C. Th. Uphof.*

2494. SMITH, LOREN B., AND H. H. ZIMMERLEY. *Booms for spraying truck crops.* Virginia Truck Exp. Sta. Bull. 28. 83–98. 1919.—A description is given of booms best adapted to the spraying of potatoes, tomatoes, spinach, and kale. Lists of materials used in the construction of the various booms are included.—*H. A. Jones.*

2495. ZIMMERLEY, H. H., AND LOREN B. SMITH. *A study of the cost of spraying kale.* Virginia Truck Exp. Sta. Bull. 30. 121–134. 1920.—The yearly production of kale in Eastern Virginia is 368,460 barrels. For the control of cabbage worms and cabbage loopers attacking this crop, the authors recommend the use of powdered lead arsenate at the rate of 1½ pounds to 50 gallons of water. For the control of aphids, 8¼ ounces nicotine sulphate plus 5 pounds fish-oil soap to 50 gallons of water is recommended. The total cost of spraying with the lead arsenate solution when spray machine moved at the rate of 3½ miles per hour with rows 20, 24, 30, and 36 inches apart was \$1.77, \$1.47, \$1.18, and \$1.14 per acre respectively. The total cost of spraying for aphids with the nicotine sulphate and fish-oil soap solution, spray machine moving at 3½ miles an hour and the rows 20, 24, 30, and 36 inches apart, was \$3.46, \$2.89, \$2.31, and \$2.04 per acre respectively. A 2-wheel sprayer, equipped with triplex pump and gasoline engine was used. Booms, etc., used are described in bulletin 28 [see preceding entry].—*H. A. Jones.*

2496. ZIMMERLEY H. H., FRED W. GEISE, AND C. R. WILLEY. *Dusting vegetable crops.* Virginia Truck Exp. Sta. Bull. 35/36. 193–208. 1921.—This is a discussion of results obtained during 1921 at the Virginia Truck Experiment Station on dusting for insect and disease control. "In the laboratory the 3 per cent nicotine dust proved the most effective in the control of 4 species of aphids. Based on an average of the 4 species the 1, 2, and 3 per cent nicotine-impregnated dusts killed 72.2, 82.1, and 89.3 per cent, respectively. For the control of aphids (*Myzus persicae* and *Macrosiphum solanifolii*) on spinach, a hydrated lime carrier with 2 per cent nicotine-impregnated dust proved the most economical. The quantity necessary varied from 20 to 40 pounds per acre. For the control of the Colorado potato beetle (*Leptinotarsa decemlineata* Say) a dust mixture containing at least 20 per cent calcium arsenate is recommended. In the control of the cabbage looper (*Autographa brassicae* Riley) and the imported cabbage worm (*Pontia rapae* Sch) on kale and Brussels Sprouts, both Noburn and a 50 per cent calcium arsenate dust gave equally good control. The action of the Noburn was more rapid than that of the calcium arsenate."—*H. A. Jones.*

MORPHOLOGY, ANATOMY AND HISTOLOGY OF VASCULAR PLANTS

E. W. SINNOTT, *Editor*

(See also in this issue Entries 2247, 2338, 2374, 2438, 2486, 2489, 2558, 2586, 2628, 2642, 2746, 2769, 2801, 2803, 2848, 2865, 2873, 2883)

2497. BROWNE, ISABEL M. P. *Anatomy of Equisetum giganteum*. Bot. Gaz. 73: 447-468. Fig. 1-7. 1922.—The node of the young main stem, nodes of smaller fertile branches, branches initiated on the main stem, and young internodes of main stem were studied. The direction of differentiation of the metaxylem in the internode is mainly centripetal. The outer elements are the smallest, and become wider in passing inward. These lateral, internodal strands of xylem join on to the nodal wood, at which level they lose their identity. There is no indication of their persisting as strands external to the nodal wood. The protoxylem is continuous through the node. By the departure of the medianly situated tracheids to the trace the protoxylem is divided into 2 small groups which diverge and enter neighboring but separate bundles of the internode above. Each of these small strands fuses with an equivalent strand of protoxylem derived from the adjacent bundle of the internode below. The fusion is effected partly by a sudden increase in number of the protoxylem elements. The nodal wood attains a considerable height and radial depth. Wide reticulate, typically nodal tracheids appear below and persist for some distance above the departure of the traces. The protoxylem elements are situated at the interior of the xylem, and pass through the inner part of the metaxylem of the bundle in a kind of parenchymatous sheath, 2 or 4 cells in thickness. The continuity of the protoxylem of the internodes through the nodes, which, although not characteristic of all species, is not confined to *E. giganteum*, is a primitive character within the genus. The question as to whether the lateral metaxylem of the genus was primitively centripetal, as in *E. giganteum*, or primitively centrifugal, as in the other species the detailed anatomy of which is known, is left open.—B. W. Wells.

2498. BUGNON, P. *Sur la ramification dichotome dans les cotylédons*. [On the dichotomous branching of cotyledons and their veins.] Compt. Rend. Acad. Sci. Paris 174: 1194-1196. 6 fig. 1922.—From this study of *Mercurialis*, *Eschscholtzia*, and *Raphanus* to determine their ancestral characters, the author believes a cotyledon character to be ancestral if it appears during embryonic development; if it does not seem to constitute a special adaptation of the cotyledon, if it does not appear in the vegetative leaves of the same plant; or if it was present in the adult leaves of ancestral plants.—C. H. Farr.

2499. BUGNON, P. *Sur l'hypocotyle de la Mercurialis*. [On the hypocotyl of *Mercurialis*.] Compt. Rend. Acad. Sci. Paris 174: 954-957. Fig. 1-2. 1922.—The conductive apparatus in the embryo of *Mercurialis annua* was studied. There is a longitudinal intercalary growth in the hypocotyl and at the base of the cotyledons, which explains the transitory character of the primary vessels which develop there. These facts are discussed in their bearing on the theory of seedling development put forward by Chauveaud.—C. H. Farr.

2500. CAMPBELL, DOUGLAS H. *The gametophyte and embryo of Botrychium simplex Hitchcock*. Ann. Botany 36: 441-456. Pl. 16, 10 fig. 1922.—The gametophyte and embryo of this species, the smallest of the genus, are described in detail and compared with those of the other species. The gametophyte closely resembles that of *B. lunaria*, differing chiefly in the smaller development of rhizoids and less conspicuous endophytic fungus. The embryo also resembles that of *B. lunaria*, but differs in the following points: the early divisions are much more variable and irregular, in this respect resembling those of *B. virginianum*; the apical bud is much better developed; the apical cell of the stem is not tetrahedral but has a truncate base like that of *B. obliquum*; and the cotyledon is much more important. The vascular system of the young sporophyte is made up exclusively of steles belonging to the roots and leaves.—W. P. Thompson.

2501. COOKSON, ISABEL C. **Floral abnormalities in the genera *Eriostemon* and *Glossodia*.** Proc. Roy. Soc. Victoria 33: 32-38. 1 pl., 4 fig. 1921.—Four abnormal plants of *Eriostemon obovalis* Cunn. are described. The abnormal flowers had petals of normal color, but a small outgrowth containing pollen occurred on the ventral surface of many of them. The tip of the lamina was generally incurved, forming a hood around the anther. Other floral characters were normal. An extreme type of abnormality was observed less often in which the lamina of the petal is modified to form a somewhat stamen-like filamentous structure with a small expanded distal portion on which a more complex anther was placed. The structure of petal and another from unopened buds is described in detail and was found to vary somewhat.—Three plants of *Glossodia major* R. Br. possessed 2 labella and abnormal perianth segment arrangement. One showed 6 perianth segments, the 3 outer calyx lobes being similar to the 2 lateral corolla lobes in size, shape, and color. The median anterior petal formed a lip. Another specimen had a median flat petal indistinguishable from the laterals and had also 2 lips, the position of which suggested that they were due to the modification of 2 missing stamens. In a 3rd specimen the median lip was replaced by a flat petal which had fused with 2 lateral sepals to form a compound lobe.—*Eloise Gerry*.

2502. DUPLER, A. W. **A bisporangiate sporophyll of *Lycopodium lucidulum*.** Bot. Gaz. 74: 331-332. 1 fig. 1922.—An instance of 2 small sporangia appearing at the base of a single sporophyll is reported. The writer suggests as explanations the very early sterilization of the archesporial tissue or the appearance of 2 distinct groups of initials.—*B. W. Wells*.

2503. ENGLER, A. **Beiträge zur Flora von Afrika XLIX. Ueber die eigenartigen Blütenverhältnisse der Gattung *Endodesmia* Benth.** [Contributions to the flora of Africa XLIX. On the peculiar floral conditions in the genus *Endodesmia*.] Bot. Jahrb. 57: 645-648. 1 fig. 1922.—The author describes the occurrence of stamens in bundles, stating that in the Guttiferae the bundles arose by fusion, not by fission as is generally supposed. The peculiar swollen receptacle beneath the ovary of the normal flowers is described, also certain abnormal flowers probably produced by gall insects. In the abnormal flowers the stamens are separate and the receptacle is enlarged above, not below, the sepals.—*K. M. Wiegand*.

2504. GORDON, MARY. **The development of endosperm in cereals.** Proc. Roy. Soc. Victoria 34: 105-116. Fig. 1-9. 1922.—The development of the aleurone layer and the starchy endosperm was traced in barley, wheat, and oat ovules and found to be practically identical in the 3. The first endosperm cells are derived from the secondary nucleus of the embryo-sac. Nuclei pass to walls of the embryo-sac, form a lining layer, and became enclosed by cell walls. The single layer of lining cells assumes the character of a cambium and produces segment cells on its inner surface. These enlarge, remain thin-walled, become packed with starch, and form the starchy endosperm. After the cells of the endospermic cambium cease to divide they become filled with aleurone grains and the cell walls thicken; this is then the aleurone layer. Its greater respiratory activity and the presence of vitamins in it are the natural results of its being a resting cambium.—*Eloise Gerry*.

2505. JUNGE, HEINRICH. **Eigenartige Blüentriebe eines *Asparagus Sprengeri*.** [Peculiar flowering-stalk of *Asparagus Sprengeri*.] Möllers Deutsch. Gärt. Zeitg. 37: 253. 1 fig. 1922.—A 4-year-old well-developed plant produced from its center 6 entirely leafless upright flowering stems, though some of the normal overhanging leafy stems also formed flowers.—*J. C. Th. Uphof*.

2506. JURICA, HILARY STANISLAUS. **A morphological study of the Umbelliferae.** Bot. Gaz. 74: 292-307. Pl. 13-14. 1922.—This paper, which brings together the morphological studies on the Umbelliferae (84 references cited), deals with the embryo-sac development and stages subsequent thereto in *Sium cicutaefolium* and *Eryngium yuccifolium*. After taking all characters into consideration, the writer states: "The complete cyclic arrangement of floral members associated with definite numbers, the single integument, the anatropous ovule, the

absence of parietal tissue of the megasporangium, the small nucellus, and the complete tetrad of the megaspores of the Umbelliferae, all of which are general characters of the Sympetalae in contrast to those of the Archichlamydeae, from which the Umbelliferae stand so stiffly apart, prove that the Umbellales in reality belong among the Sympetalae." Within the latter group the writer believes they should be placed parallel to the Rubiales in such manner as to indicate a common origin for both groups.—*B. W. Wells.*

2507. NICOLAS, G. Des synanthies, à propos du *Narcissus Tazetta* L. [On synanthly, especially in *Narcissus Tazetta*.] *Compt. Rend. Acad. Sci. Paris* 174: 1126–1128. 1922.—This instance of teratology is carefully described and used as confirmation of the ligular theory of the crown of the *Narcissus* blossom. It is concluded that all cases of synanthly, syncarpy, and fasciation, and all anomalous characteristics of non-dissociation and of concrescence of buds, are not due to an excess of nutrition, but to deficient nutrition.—*C. H. Farr.*

2508. NISHIMURA, MAKOTO. Comparative morphology and development of *Poa pratensis*, *Phelum pratense* and *Setaria italica*. *Japanese Jour. Bot.* 1: 55–85. 4 pl., 53 fig. 1922.—Germination and the development of root and shoot, inflorescence and embryo were studied. Marked differences were noted in rate and percentage of germination, *Setaria* exceeding the others in both. The characteristic hairs developed at the tip of the coleorhiza are described. *Poa* and *Phleum* (both perennials) develop compact stools the 1st season but *Setaria* (an annual) forms only a single leafy culm. In the 2nd season each shoot of *Phleum* produces a stout, corm-like body which is lacking in *Poa*. Plants sown from seed at different dates during the growing season differ markedly in many features. Development of the root system was studied and various differences noted between the 3 genera; all are shallow rooted, and 2 roots are usually associated with each bud. The root-hair zone frequently extends over the whole root and the hairs may last into the 2nd season. The inflorescence is developed in all cases from a vegetative cone through the production of a series of lateral, spike-forming primordia. The embryo develops normally but polyembryony occurs somewhat commonly in *Poa*. Abnormal ovaries frequently appear following the stings of an insect.—*E. W. Sinnott.*

2509. OELKERS, FRIEDRICH. Entwicklungsgeschichte von *Monophyllaea Horsfieldii*. [Development of *Monophyllaea Horsfieldii*.] *Beih. Bot. Centralbl.* I Abt. 39: 128–151. Pl. 15, 12 fig. 1922.—The seed germinates in 14–21 days after ripening. The young seedling shows 2 equal cotyledons which later become unequal. The root develops exogenously from the end of the hypocotyl, but the lateral roots develop endogenously. The development of the inflorescence and ovules is described. The egg and synergids are as usual, but it was not determined whether antipodals are present or whether the polars fuse. Pollen development is normal. The diploid chromosome number is 32. Double fertilization takes place. The young undifferentiated embryo has a large haustorium; later 2 equal cotyledons develop.—*L. Pace.*

2510. PAMMEL, L. H., AND C. M. KING. The germination of some trees and shrubs and their juvenile forms. *Proc. Iowa Acad. Sci.* 27: 75–80. [Fig. 10–11. 1920.—] Figures and descriptions are given of the seedlings (cotyledons and first leaves) of *Populus deltoides*, *Ulmus racemosa*, *Berberis macroacantha*, *B. laxiflora oblanceolata*, *Citrus decumana*, *Ampelopsis heterophylla*, *Ptelea trifoliata*, *Nyssa sylvatica*, *Diospyros virginiana*, and *Fraxinus americana*.—*H. S. Conard.*

2511. POHL, FRANZ. Zur Kenntnis unserer Beerenfrüchte. [Our berry-fruits.] *Beih. Bot. Centralbl.* I Abt. 39: 206–221. 1922.—The fruits of several species of *Ribes* are described in some detail. The development of berry-fruits from the arillus is rare. *Taxus* and *Podocarpus* have fleshy arilli, as does the cactus. The fruit of *Garcinia* is developed largely from the arillus, but the origin of that of *Podophyllum* needs further investigation. *Ribes* shows considerable variation in the relative amount of the fruit coming from the arillus. This structure produces the greater part of the berry in *R. nigrum*, *R. aureum*, and *R. alpinum*, but

the pericarp forms the greater part in *R. rubrum*, *R. gracile*, and *R. canescens*. In the large pericarp berry of *R. grossularia* the arillus is much reduced. It is not easy to decide whether the pericarp or the arillus type of berry is the older.—*L. Pace*.

2512. PRINTZ, H. Det vegetative skuds anatomiske bygning hos *Phelipaea lanuginosa*. C. A. Meyer. [The anatomy of the vegetative sprout in *Phelipaea lanuginosa*.] K. Norske Videnskab. Selskab. Skrifter 1921: 1-49. Pl. 1-4, fig. 1-31. 1922.—The external features of *Phelipaea lanuginosa* are typical of the *Orobanchaceae*. The morphological features of this species are here discussed. Surrounding the vascular bundles a sclerenchymatic sheath is often developed which is very different in different individuals, and in the opinion of the author is an adaptional phenomenon and can not be used for specific distinctions as previously supposed. The stomata are numerous for a parasitic plant, and their position is also remarkable. In some, the guard-cells lie at the same level as the epidermis, but in others they are elevated high above the cells of the epidermis. The 2 kinds may occur together, and it is probable that they serve different purposes. Starch is found in the guard-cells, but chlorophyll is absent throughout the whole plant. The trichomes are different from those previously described for the family, as they are composed of a row of long, cylindrical, thin-walled living cells. The cells of the epidermis, and often also of the outer layers of the bark, are destroyed rather early and form a very effective obstacle to transpiration. The veins are collateral and in this respect differ from other related plants in which the veins are reported to be hadrocentric. The short and vermiform roots possess little or no geotropical sensitiveness. Two roots are occasionally connected by means of haustoria, which are anatomically similar to those which unite the plant with its host. There is also a tendency toward reciprocal accretion between the roots, but in this case only epidermis and bark are united. These 2 phenomena are probably due to the same cause, probably a kind of contact stimulation. [A German résumé is appended.]-*K. Münster Ström*.

2513. SCHMIDT, E., UND E. GRAUMANN. Zur Kenntnis pflanzlicher Inkrusten. I. Mitteilung: Methode zur Reindarstellung pflanzlicher Skelettsubstanzen. [Contributions to our knowledge of plant incrustations. I. Methods for the purification of skeletal plant substances.] Ber. Deutsch. Chem. Ges. 54: 1860-1873. 1921.—A method is presented by means of which the skeletal substance (cellulose) of plants can be separated from incrustations (e.g., lignin).—*Henry Schmitz*.

2514. SEARS, PAUL BIGELOW. Variation in cytology and gross morphology of *Taraxacum*. II. Senescence, rejuvenescence and leaf variation in *Taraxacum*. Bot. Gaz. 73: 425-446. Fig. 1-9. 1922.—The author believes that variations arising from senescence and from ecological causes constitute characters which have often been used in creating species. He shows that "while bracts and achenes are conceded to afford critical characters, the leaves are actually given great weight in spite of their variability." In inducing leaf variations senescent and rejuvenescent changes are prime factors. "Senescence produces a steadily increasing degree of dissection and frequently of hairiness; rejuvenescence restores the unsegmented juvenile seedling form." Changes toward senescence are not correlated with absolute leaf area, total xylem duct capacity in successive leaves, mean xylem duct capacity in successive leaves, ratio of total capacity to leaf area, or number of vein islets per unit area. A definite increase of the carbohydrate-nitrogen ratio is related to senescence. "The time of seeding may govern time of flowering and rejuvenation: this in turn may affect degree of dissection in plants at flowering time." Thus "pure stands of distinctive variants in certain cases may be explained by environmental control of seed germination time." Fluctuations in plant parts other than the leaves are in many cases due to ontogenetical and environmental conditions, but for the most part to unknown causes. It is held that a considerable number of published species are merely variants of *T. vulgare* and *T. laevigatum* caused by the interplay of the various factors operating in senescent change and in the environment.—*B. W. Wells*.

2515. SINNOTT, E. W., AND I. W. BAILEY. The significance of the 'foliar ray' in the evolution of herbaceous angiosperms. *Ann. Botany* 36: 523-534. *Pl. 18-19, 1 fig.* 1922.—The authors had previously expressed the opinions that the chief anatomical concomitant of the change from the woody to the herbaceous habit is simply a progressive thinning of the woody ring, that herbaceous stems are essentially similar in structure to their woody ancestors, and that the woody ring of many-bundled herbs is dissected by high multiseriate rays which are not subtended by woody elements. These conclusions have been attacked by Jeffrey and Torrey, who hold that a new structure, the foliar ray, subtended by woody elements (traces) has made its appearance in the evolution of woody herbs from trees or shrubs and that these woody or transitional herbs have given rise in turn to more herbaceous types by the loss of the confronting portion of the ray and a downward extension of its flanking portions. After clearing up certain misapprehensions and reaffirming the correctness of their original observations, the authors present evidence to show that (1) the 'foliar rays' include several distinct structures, (2) many trees possess foliar rays and are therefore in the first annual ring precisely comparable to herbs, and (3) many herbs have no foliar rays but a continuous vascular cylinder. They conclude that their critics' hypothesis is not tenable because (1) it cannot explain the origin of herbs with continuous cylinders and (2) it involves the evolution and subsequent loss of a transitional structure when the facts are more easily and simply explained without such an assumption.—*W. P. Thompson.*

2516. SOUEGES, RENÉ. Embryogénie des Rosacées. Les premiers stades du développement de l'embryon chez le *Geum urbanum* L. [Embryogeny of the Rosaceae. The first stages in the development of the embryo of *Geum urbanum*.] *Compt. Rend. Acad. Sci. Paris* 174: 1070-1072. *Fig. 1-15.* 1922.—A detailed description and figures are given of the stages in development of this species. Some points of similarity are found between its embryogeny and that of *Capsella Bursa-pastoris*. [See also following entry].—*C. H. Farr.*

2517. SOUEGES, RENÉ. Embryogénie des Rosacées. Les derniers stades du développement de l'embryon chez le *Geum urbanum* L. [Embryogeny of the Rosaceae. The later stages of development of the embryo of *Geum urbanum*.] *Compt. Rend. Acad. Sci. Paris* 174: 1197-1199. 1922.—A new type of embryo development akin to that of *Myosotis hispida* is reported. [See also preceding entry].—*C. H. Farr.*

2518. THODAY, D. On the organization of growth and differentiation in the stem of the sunflower. *Ann. Botany* 36: 489-510. *Pl. 17, 10 fig.* 1922.—In the primary leaf-trace bundles the whole of the xylem originates from a cambium which arises near the inner margin of the procambial crescent. The bulk of the crescent differentiates as phloem. New bundles are interpolated between the primary ones. The transverse growth of a leaf-trace is correlated with that of its leaf and not that of the internode as a whole. Though the xylem portions of the entering leaf-traces remain independent, the strands of the phloem which accompany them connect laterally with those of adjacent bundles, thus making a shorter circuit for the movement of food. Secondary growth is at first due to the cambium of "synthetic traces" which communicate directly with the expanding upper leaves. This growth is in large part tangential, so that the pith becomes distended and often hollow. Meantime the cambium in the mature leaf-trace bundles remains inactive for a considerable time and only gradually resumes growth. The mode of growth is the same in all parts of the stem as in the basal internode. The differences in appearance are due merely to the fact that the upper regions represent an earlier phase in ontogeny, and to the larger scale of the primary tissues in the upper part. Phylogenetic inferences with respect to the origin of herbs as adduced from a comparison of the base with the upper parts are not justified.—*W. P. Thompson.*

MORPHOLOGY AND TAXONOMY OF ALGAE

(See in this issue Entries 2328, 2329, 2557, 2636, 2637, 2638, 2668, 2671, 2727, 2769, 2783, 2846)

MORPHOLOGY AND TAXONOMY OF BRYOPHYTES

ALEXANDER W. EVANS, *Editor*

(See also in this issue Entries 2320, 2331, 2846)

2519. ANONYMOUS. **Hepatics.** Moss Exchange Club Sec. II Rept. [Bewdley] 1917: 14-18. 1918.—The Hepaticae distributed during 1917 numbered 67 species and included *Prionolobus striatulus*, new to Wales. The specimens were all collected in the British Isles except 8 from Switzerland. In a few instances D. A. J[ONES] has contributed critical remarks.—A. W. Evans.

2520. ANONYMOUS. **Hepatics.** Moss Exchange Club Sec. II Rept. [Bewdley] 1918: 22-25. 1919.—The specimens of hepatics distributed in 1918 include 57 species and were all collected in the British Isles. A few critical notes by D. A. J[ONES] accompany the report.—A. W. Evans.

2521. ANONYMOUS. **Hepatics.** Moss Exchange Club Sec. II Rept. [Bewdley] 1919: 21-27. 1920.—Of the 89 species of hepatics listed in the 1919 distribution, 3 came from Switzerland, 2 from Italy, and the others from the British Isles. D. A. J[ONES] has commented on a few of the specimens.—A. W. Evans.

2522. ANONYMOUS. **Mosses.** Moss Exchange Club Sec. II Rept. [Bewdley] 1917: 8-13. 1918.—The specimens of mosses distributed during 1917 included 76 species: with the exception of 3 from Switzerland, all came from the British Isles. A few critical notes are contributed by D. A. J[ONES], G. B. S[AVERY], W. R. S[HERRIN], and J. A. W[HELDON].—A. W. Evans.

2523. ANONYMOUS. **Mosses.** Moss Exchange Club Sec. II Rept. [Bewdley] 1919: 8-21. 1919.—Of the 176 species of mosses listed in the 1918 distribution, 17 came from Switzerland, 1 each from Bavaria, Canada, Italy, and Salzburg, and the others from the British Isles. The critical notes interpolated throughout the list are by J. AMANN, D. A. J[ONES], G. B. S[AVERY], W. R. S[HERRIN], and J. A. W[HELDON].—A. W. Evans.

2524. ANONYMOUS. **Mosses.** Moss Exchange Club Sec. II Rept. [Bewdley] 1919: 8-20. 1920.—The mosses listed as having been distributed in 1919 include 150 species. Of these 14 were collected in Switzerland, 3 in Italy, 1 each in France, Poland, Salzburg, and Tirol, and the others in the British Isles. Critical notes on certain of the specimens are by E. R[ILSTONE], D. A. J[ONES], G. B. S[AVERY], W. R. S[HERRIN], and J. A. W[HELDON].—A. W. Evans.

2525. ANONYMOUS. **Notes.** Bryologist 25: 93-94. 1922.—There are noted the deaths of Egidio Corti and of Abbé Faurie, the sale of collections from the Zoologische-botanische Gesellschaft of Vienna, and the appearance of fascicle 19 of J. M. Holzinger's *Musei Acrocarpi Boreali-Americani*, with a list of the species included in the fascicle.—E. B. Chamberlain.

2526. BRITTON, ELIZABETH G. **On some mosses from the Blue Mountain of Cuba.** Bryologist 25: 89-90. 1922.—An annotated list of 6 somewhat uncommon mosses from the summit of Pico Turquino, Cuba, is given; 3 of the species are new to the island.—E. B. Chamberlain.

2527. DIXON, H. N. The mosses of the Oxford University expedition to Spitzbergen, 1921. *Bryologist* 25: 86-89. 1922.—This is an annotated list of 18 species and varieties of mosses, 5 of the species representing additions to the known flora of Spitzbergen. There is a summary of previous publications on the Spitzbergen mosses, and descriptive notes on a number of the species are included. *Bryum globosum* Lindb. var. *ruberrimum* from Klaas Billen Bay is proposed as new, and a 3rd locality for *Calliergon sarmentosum* var. *fontinaloides* Berggr. is noted.—E. B. Chamberlain.

2528 DIXON, H. N. Note on a form of *Pottia Heimii* from Greenland. *Bryologist* 25: 92-93. 1922.—The author describes a specimen of the moss *Pottia Heimii* Fuernr. from Ata, Greenland, which shows a combination of characters usually pertaining to distinct varieties of this species. He concludes that the material should be classified as a form approaching var. *obtusifolia* (R. Br.) Hag.—E. B. Chamberlain.

2529. DUNK, KURT VON DEN. Monographie des Leuchtmooses (*Schistostega osmundacea* Web. et Mohr). [Monograph on the luminous moss.] 8vo, 57 p., 4 pl. Inaug. Diss. Frankfurt am Main, 1921.—The author discusses the moss from various points of view, including: taxonomy and history of the species; features of the protonema, including the lens-cells and the gemmae; origin and morphology of the leafy stems; heliotropism of the sterile shoots; branching and production of sexual organs by the fertile shoots; development and structure of the sporophyte; nature of the habitat and geographical distribution; bryophytes usually associated with the species. The following are the more important of the conclusions reached: the significance of the lens-cells has been overestimated; spindle-shaped gemmae represent the only type produced; both the male and female inflorescences can branch, this process being especially frequent in the male inflorescence; the dioecism of the species manifests itself in the leafy shoots only and not in the protonema; moisture and a fairly dim light are necessary for the development of the plants; the species grows on a variety of substrata, preferring sandstone and avoiding lime; and its distribution is in the Temperate Zone of the Northern Hemisphere, its altitudinal range extending from 30 to 1400 m. The plates illustrate morphological and anatomical features.—A. W. Evans.

2530. DUPLER, A. W. Early embryogeny of *Reboulia hemisphaerica*. *Bot. Gaz.* 74: 143-157. 47 fig. 1922.—According to the author's observations the fertilized egg in *Reboulia hemisphaerica* soon gives rise to a filament of 4 cells usually separated by transverse walls. The next divisions are commonly vertical, each cell except the basal forming a tier of 4 cells. Even in the early stages variations frequently occur and the walls may be oblique rather than transverse or vertical; in fact an apical cell cutting off a few segments is sometimes evident in the upper part of the young sporophyte. In all probability the epibasal cell, formed by the 1st division of the egg, gives rise to the capsule only, as in most Marchantiales, while the hypobasal cell gives rise to the stalk and foot. There is no absolute proof, however, that the epibasal cell may not contribute to the stalk region as in the Jungermanniales. Neither is it certain that the 1st periclinal walls in the upper portion cut off the future capsule-wall from sporogenous tissue, although this is probably the case. The author makes frequent allusions to the recent studies of Haupt and Woodburn [see *Bot. Absts.* 4, Entry 1045], as well as to the older literature, and concludes, from the variations in early embryogeny, "that *Reboulia* is a plastic form, and as such may occupy a genetic position among the Hepaticae."—A. W. Evans.

2531. EVANS, ALEXANDER W. Recent studies on certain species of *Riccia*. *Bryologist* 25: 81-86. 1922.—Transitional forms, whose thalli in width and in the structure of the air chambers break down the differences upon which *Ricciella* is maintained as a genus distinct from *Riccia*, make it advisable to consider the 2 groups as but a single genus. The status of the plants called *Riccia fluitans* L. appears to be in doubt. Evidence at present known is conflicting as to whether the plants represent a real species, an aquatic form of a single species, or an aggregate of the aquatic forms of several species. The author summarizes papers by

Torka, Donaghy, von Gaisberg [see Bot. Absts. 11, Entry 464], and Familler [see Bot. Absts. 6, Entry 1207], which detail cultural experiments and field observations upon the question of the relationships between *R. fluitans*, *R. canaliculata*, *R. Huebeneriana*, *R. pseudo-Frostii*, and *R. Sullivantii*, and points out the absence of conclusive data in many cases. There is need for more critical research upon the question and for controlled cultural experiments. The bibliography lists nine titles.—*E. B. Chamberlain*.

2532. FLEISCHER, M. [Rev. of BROTHERUS, V. F. *Musci Weberbaueriani*. (Weberbauer's mosses.) Bot. Jahrb. 56: 1-22. 1920 (see Bot. Absts. 6, Entry 1906).] Hedwigia 63: (Beiblatt) 6. 1922.—The reviewer speaks of the great interest, from the standpoint of plant geography, of the European mosses which the author reports from the Peruvian Andes. Among such species he cites the following: *Bryum bimum*, *Distichium capillaceum*, *Hygroamblystegium filicinum*, and *Splachnum ampullaceum*.—*A. W. Evans*.

2533. HARRIS, G. T. The moss flora of Sidmouth and neighbourhood. Trans. Devonshire Assoc. Adv. Sci. Lit. and Art 50: 561-582. 1918.—The region investigated is mostly comprised within a distance of 5 miles from the town of Sidmouth in East Devon and had previously received less attention than the other parts of Devonshire. The altitudinal range extends from the sea level to a height of over 800 feet. The varied features of the district and the characteristic mosses found in the various kinds of habitat are described in considerable detail, and the paper gives also a "census list of the moss flora," in which 201 species are enumerated, with data regarding frequency and often with the indication of definite stations. In a few cases critical or morphological remarks are added. Six varieties of mosses collected at Dartmoor and representing new county records are reported, 1 being *Hypnum falcatum* Brid. var. *delicatulum* Dixon, described as new.—*A. W. Evans*.

2534. HURST, C. P. North Somerset mosses. Jour. Bot. 56: 268-270. 1918.—The author gives a report on a collection of mosses which he made during the winter of 1916-17 near Burnham-on-Sea, Somerset, England. He enumerates 38 species, varieties, and forms, giving full data regarding localities and, in several cases, including critical remarks. Of the mosses collected 7 represent new vice-comital records.—*A. W. Evans*.

2535. LUISIER, A. Les mousses de Madère (suite). [Madeiran mosses.] Brotéria Sér. Bot. 20: 76-106. 1922.—The present instalment contains keys to the genera and species of the families Polytrichaceae to Brachytheciaceae, with references to the author's earlier articles [see Bot. Absts. 8, Entry 1265; 9, Entry 1507; 10, Entry 1840].—*E. B. Chamberlain*.

2536. THÉRIOT, I. *Leptobryum Escomeli* Thér. sp. nov. Bryologist 25: 90-92. 1922.—The new species of moss here described and figured is from near Arequipa, Peru, and is based on material collected by E. Escomel and R. S. Williams. It is most closely related to *Leptobryum Wilsoni* Broth., figures of which are given for comparison.—*E. B. Chamberlain*.

MORPHOLOGY AND TAXONOMY OF FUNGI, LICHENS, BACTERIA, AND MYXOMYCETES

H. M. FITZPATRICK, *Editor*

D. S. WELCH, *Assistant Editor*

(See also in this issues Entries 2311, 2321, 2322, 2577, 2582, 2584, 2589, 2598, 2611, 2616, 2620, 2668, 2683, 2700, 2750, 2769, 2785, 2844, 2846)

FUNGI

2537. BERGER, E. W. Another apparently new entomogenous fungus from the hammock. Proc. Florida State Hort. Soc. 35: 68-71. 1922.—*Aschersonia basicystis*, an orange-colored fungus, was found in a hammock at Winter Park, Florida. This fungus was collected inde-

pently by C. A. Reese and E. W. Berger, infecting unidentified white fly larvae on *Ilex opaca*. The existence of this fungus on a native fly in Florida is of considerable interest.—*J. C. Th. Uphof*.

2538. CAVADAS, C. S. Étude morphologique, histologique et cytologique d'une mycocécidie provoquée chez l'*Urtica dioica* L. par le *Puccinia Caricis* (Sch.) Rebert. [Aecidia of *Puccinia Caricis* on *Urtica dioica*.] 16 p., 3 pl., 2 fig. Faculté Sci.: Nancy, 1922.—In the pseudoperidium around the aecidiospores of *P. Caricis*, the so-called "sterile cells" of Grove are considered equivalent to the uninucleate cells differentiating from the basal cells at the bottom of the young aecidia. The cells of the pseudoperidium are considered homologous to the aecidiospores. The mycelium has a solvent action on pectic and lignified walls; attacked cells react through hyperplasia or hypertrophy, and their nuclei swell or divide either by mitosis or amitosis.—*J. Dufrenoy*.

2539. DUFF, G. H. Development of the Geoglossaceae. Bot. Gaz. 74: 264-291. Pl. 8-12. 1922.—The author presents the significant stages related to the development of the ascocarp and to sexuality of *Cudonia lutea*, *Spathularia velutipes*, *Trichoglossum hirsutum*, and *Leotia lubrica*. He finds in the Helvellineae a morphological situation involving the veil which finds a parallel in the Baeomyces group of disco-lichens; this is adduced as evidence of relationship. Fructification in *Cudonia* and *Spathularia* is initiated by "generative hyphae" which give rise to the procarps from which the ascogenous hyphae spring. The procarp of *Cudonia* bears a trichogyne, a structure lost in *Spathularia*. Further reduction characterizes the other genera. Progressive reduction of the sex organs has characterized evolutionary progress. In this latter regard also the Geoglossaceae are in close correspondence with the Baeomyces group of disco-lichens.—*B. W. Wells*.

2540. КУРСАНОВ, Л. [KURSSANOW, L.] Морфологические и, цитологические исследования в группе Uridineae. [Morphological and cytological investigations in the Uredineae.] 228 p., 151 fig. Moscow. 1915.—A considerable part of this work consists of the author's studies of the development of the rusts not having aecial forms, 18 species having been investigated. *Uromyces scutellatus*, *U. laevis*, *U. Alchemillae*, *U. Ficariae*, *Puccinia Fergussoni*, *P. suaveolens*, *P. Rossiana*, *P. Aegopodii*, *P. Arthemisiae*, *P. Asarina*, *P. Allii*, *P. Iridis*, *P. Helianthi*, *Triphragmium Ulmariae*, *Chrysomyxa Abietis*, *C. Pirolae*, *Melampsora* sp., *Hyalopsora Polypodii-Dryopteridis*. He discusses in detail the morphological significance of the mutual relationship of the various types of spores in this group and explains their evolution and the questions of sexuality. In the study of the aecial fructification, in addition to the manner of formation of the first binucleate cells, he takes into consideration the time of their appearance, the general structure of the fructification, the formation of the sterile pseudoparenchyma and the relation of the latter to the sterile cells (Blackman's trichogynes). The types of aecial fructification are arranged in a series at one extreme of which is placed *Aecidium* and at the other *Caeoma*. *Aecidium* represents the primitive type, the simpler form of *Caeoma* having resulted through a regressive evolution. An interesting parallelism is observed between the aecia and the primary uredinia and telia in brachy, micro, hemi, and other shortened cycles. The shortened cycles are the more recent, the primary uredinia and telia developing instead of the lost aecial fructification possessed by the primitive forms. The author gives a detailed analysis of the data upon which is based Blackman's theory that the fruiting cells are differentiated female cells. It is shown that the presence of the continuous fruiting layers in the primary fructification cannot be considered as exclusively characteristic of sexual cells. Similar layers are present also in the secondary sori (*Puccinia Helianthi*, *Triphragmium*, etc.). The actions of the nuclei are also not exclusively characteristic of the sexual nuclei. Finally, instability of the sterile cells, dependence of their formation upon outside conditions, their connection with the sterile tissues (*Peridermium*, *Aecidium*), and their presence in the secondary sori (*Triphragmium*, *Puccinia Iridis*, *Melampsoraceae*), oppose the point of view that these sterile cells are atavistic organs of morphological significance. The author considers the sexual process in the present

day Uredineae as a purely apogamic phenomenon to which could be applied the term pseudomixis of Winkler; and he draws a scheme of the evolution of the sexual process which begins with a hypothetical sexual form and ends with a purely apogamic modern aecium. The development of the peridium in different types of aecia is studied. Experiments to demonstrate functioning of the spermatia gave negative results (*Melampsora Rostrupii*). Reduction division was found (*Coleosporium Tussilaginis*) to deviate from the ordinary; that is, in the stage of meta-anaphasis, there are 16 chromosomes.—*S. Satin*.

2541. MARTIN, G. W. The mycoplasm theory. [Rev. of: ERIKSSON, JAKOB. (1) The mycoplasm theory, is it dispensable or not? *Phytopathology* 11: 385-388. 1921 (see Bot. Absts. 11, Entry 2870). (2) The life of *Puccinia Malvacearum* Mont. within the host plant and on its surface. *Phytopathology* 11: 459-463. 1921 (see Bot. Absts. 11, Entry 2869). (3) Das Leben des Malvenrostpilzes (*Puccinia Malvacearum* Mont.) in und auf der Nahrpflanze. (The life of *Puccinia Malvacearum* Mont. in and on the host plant.) *Handl. K. Svensk. Vetenskapsakad.* 62⁵: 1-190. *Fig. 1-31*. 1921.] *Bot. Gaz.* 74: 337-338. 1922.—The reviewer points out that "the widespread opposition to the mycoplasm theory is based on the feeling that the facts may ultimately be accounted for satisfactorily without the theory."—*B. W. Wells*.

2542. SALVAT, P., et M. FONTOYNOT. Contribution à l'étude des Mycoses malgaches. Abcès sous-dermiques dus à l'Endomyces Molardi (n. sp.). [Contribution to the study of Madagascar mycoses. Sub-dermal abscess due to *Endomyces Molardi* n. sp.] *Bull. Soc. Path. Exotique* 15: 311-320. *Fig. 1*. 1922.—The authors describe a new case of mycosis at Tananarive. There are large numbers of infections of fungous origin in the tropical and sub-tropical regions. Many of these are contracted in the warm moist coast regions, and continue to develop even when the carrier attains a higher altitude and a cool, or at least a temperate, climate. The symptoms of the disease are described and its cure in the course of about 2 months by the application of methylene blue.—The culture of the organism is simple. Inoculations were made directly from the abscess after washing with hydrogen peroxide followed by sterile water. Growth is good on most common media, but best on carrot-glycerin, glycerin-gelatine, and unneutralized lactose bouillon. The different forms of the parasite should be studied on liquid media, since the round or oval forms and the filaments are hard to find on solid media. The growth and appearance of the organism on different media are described at considerable length. Its appearance varies according to the medium and the age of the culture. Usually several forms are to be seen together with a predominance of one or another. The filaments are cylindrical, simple or branched, of considerable length, 2-6 μ in diameter, and sometimes constricted at the septa. The septa are irregularly spaced, generally closer together at the distal ends. Some hyphae have a thick wall, while in others it is very delicate. The younger hyphae have finely granular protoplasm, easily stained; the older become vacuolate, and are not easily stained by the analin stains. The filaments may be terminated (1) by a long cell, (2) by a chain of small thick-walled cells, yeast-like in appearance, or (3) by large spherical thick-walled chlamydospores 8-22 μ in diameter. Chlamydospores may be terminal, or they may occur on short side branches or even on the side walls of a filament. Chlamydospores and yeast-like cells frequently may be seen separated from the filaments in groups or isolated. Endospore-like bodies in chains in a filament were also observed. The yeast-like cells may bud and produce filaments or chains of cells like themselves. Certain old cultures developed asci which were spherical or elliptical, were only lightly stained, and contained 4 or rarely 8 ascospores. All the stages of the organism are shown in the figure. Experiments with guinea pigs are described. The authors consider this to be a new pathogenic *Endomyces*, close to but different from *E. albicans* Muguet, and propose the name *Endomyces Molardi*.—*G. H. Godfrey*.

2543. SARTORY, A., et L. MAIRE. Compendium Hymenomycetum. Fasc. I. *Amanita*. 24 p., 2 pl. Le François: Paris.

2544. TORREND, C. *Les polyporacées du Brésil (suite)*. [Brazilian polypores (continued).] *Brotéria Sér. Bot.* 20: 107-112. 1922.—This installment includes the 9 species of *Lignosus* recognized as occurring in Brazil, with brief descriptions, notes upon collections, and an analytic key. The author also discusses several tropical forms that should be compared with Brazilian forms, without venturing any opinion as to their identity. [See also *Bot. Absts.* 8, Entry 1314.]-*E. B. Chamberlain*.

LICHENS

2545. FRY, E. J. *Some types of endolithic limestone lichens*. *Ann. Botany* 36: 541-562. *Pl.* 31, 9 fig. 1922.—This is a study of certain lichens which grow embedded in limestone. The structure of the thallus is similar to that of sub-aerial forms. A classification based on thallus structure is given. In regions of special growth where there is rapid solution of the limestone, numerous spherically inflated hyphae containing oil are found. In slower growing regions oil globules are found in ordinary hyphae. The oil is a waste material. The carbon dioxide of respiration dissolves the rock by forming the soluble bicarbonate. This is precipitated at the surface of the thallus as stable carbonate, causing the granular appearance of the surface of the thallus.—*W. P. Thompson*.

2546. SAMPAIO, GONÇALO. *Materiais para a liquenologia portuguesa*. [Materials towards a Portuguese lichen flora.] *Brotéria Sér. Bot.* 20: 147-163. 1922.—A much annotated list is given of 60 species or varieties of lichens, representing additions to the flora of Portugal or new facts in distribution. Descriptive notes accompany most items. There is 1 new combination, *Catillaria Lightfootii* (Sm.) Samp. (*Biatorina*), and 3 forms are proposed as new, viz: *Verrucaria Carrisoi*, *Polyblastia exigua*, and *Lecidia flavigrana*, all of Sampaio.—*E. B. Chamberlain*.

BACTERIA

2547. ALMQUIST, ERNEST. *Variations and life cycles of pathogenic bacteria*. *Jour. Infect. Diseases* 31: 483-493. 1922.—Studies upon mutation in *B. typhosus*, *Sp. cholera*, *B. diphtheria*, and *Microc. Thulini* when exposed to a considerable range of experimental conditions are reported. Numerous references are also made to the literature upon the subject and space is given to the consideration of the present terminology.—*R. V. Allison*.

2548. BREED, ROBERT S. *Some problems in the nomenclature of bacteria*. [Abstract.] *Absts. Bact.* 6: 484. 1922.—*Bacterium* as a generic name is not justified on nomenclatorial grounds. Breaking up of the colon-typhoid group into distinct genera will soon eliminate the name. *Erythrobacillus* of Fortineau has for its type *E. pyosepticus*, not *E. prodigiosus* Ehren. The first valid name for the red chromogenic rods is *Serratia* of Bizio and the type is *S. marescens*.—*D. Reddick*.

2549. DUBOVSKY, BERTHA J., and K. F. MEYER. *An experimental study of the methods available for the enrichment, demonstration and isolation of B. botulinus in specimens of soil and its products, in suspected food, and in clinical and in necropsy material*. *Jour. Infect. Diseases* 31: 501-540. 1922.—Methods for the enrichment and demonstration of *B. botulinus* are described in detail. Emphasis is laid upon the possible danger of laboratory contamination. The methods applicable for examination of suspected food and clinical and necropsy material are also described in full.—*R. V. Allison*.

2550. DUBOVSKY, BERTHA J., and K. F. MEYER. *The distribution of the spores of B. botulinus in the territory of Alaska and the Dominion of Canada*. V. *Jour. Infect. Diseases* 31: 594-599. 1922.—These studies show that the organism has not been demonstrated in the coast land soil of the Aleutian Archipelago. *B. botulinus*, type A and occasionally type B, has been cultivated in moraine, glacier, and mountain soil collected around Lake Louise in the Canadian Rockies. Likewise soil samples obtained from the provinces of Prince Edward Island, Nova Scotia, Quebec, Ontario, and British Columbia have furnished positive cultures.—*R. V. Allison*.

2551. DUBOVSKY, BERTHA J., and K. F. MEYER. The occurrence of *B. tetani* in soil and on vegetables. VIII. Jour. Infect. Diseases 31: 614-616. 1922.—The spores of *B. tetani* are frequently encountered in well manured, cultivated, or garden soil, and on vegetables obtained from Switzerland, China, and several states east of the Mississippi. In the U. S. A. even virgin forest soil has yielded cultures of *B. tetani*. The soil of the western states is relatively free from this anaerobe.—R. V. Allison.

2552. HUCKER, G. J., and W. A. WALL. The use of agar slants in detecting ammonia production by bacteria and its relation to the reduction of nitrates. [Abstract.] Absts. Bact. 6: 485. 1922.

2553. MEYER, K. F., and BERTHA J. DUBOVSKY. The distribution of *B. botulinus* spores in California. II. Jour. Infect. Diseases 31: 541-555. 1922.—Examinations from widely separated groups of soils, vegetables, fruit, etc., showed *B. botulinus* to be very widely distributed. Evidence is found upon which the authors base the suggestion that the natural habitat of the organism is in the virgin field and forest.—R. V. Allison.

2554. MEYER, K. F., and BERTHA J. DUBOVSKY. The distribution of the spores of *B. botulinus* in the United States. IV. Jour. Infect. Diseases 31: 558-594. 1922.—A study of widely scattered samples from every state except Virginia shows that *B. botulinus* is a common anaerobe in the soils of the western states of the Cordilleran System. It is less frequently found in the Atlantic States, the Great Plains, and the Mississippi valley. The spores of the organism were found to be much more numerous in the virgin and pasture soils than in dirt, soil, or manure obtained from animal corals, etc.—R. V. Allison.

2555. MEYER, K. F., and BERTHA J. DUBOVSKY. The occurrence of spores of *B. botulinus* in Belgium, Denmark, England, the Netherlands and Switzerland. VI. Jour. Infect. Diseases 31: 600-609. 1922.—*B. botulinus* has been demonstrated in soil and vegetable specimens collected in all of the countries mentioned. Type A has been consistently absent. While the spores are widely distributed, they are neither numerous nor very resistant to heat.—R. V. Allison.

2556. ROSEN, H. R. The bacterial pathogen of corn stalk rot. Phytopathology 12: 496-499. 1922.—A brief description is given and the name *Pseudomonas dissolvens* is suggested for the organism causing a stalk-rot of corn (*Zea mays* L.).—B. B. Higgins.

PALEOBOTANY AND EVOLUTIONARY HISTORY

E. W. BERRY, *Editor*

(See also in this issue Entries 2338, 2873)

2557. BELL, W. A. A new genus of Characeae and new Merostomata from the Coal Measures of Nova Scotia. Trans. Roy. Soc. Canada (3) 16: 159-167. Pl. 1. 1922.—The author describes undoubted oogonia of *Palaeochara*, a new genus of charophyte characterized by having 6 instead of 5 investing cells and constituting the most ancient known undoubted member of this group.—E. W. Berry.

2558. BENSON, MARGARET. *Heterotheca Grievii* the microsporangium of *Heterangium Grievii*. Bot. Gaz. 74: 121-142. Pl. 4-5, fig. 1-8. 1922.—Sporangia are described from the Pettycur deposits of the Calcareous Sandstone Series of Scotland (Lower Carboniferous) associated with *Heterangium Grievii*. The sporangia resemble *Telangium Scottii*, but have distinctive characters which do not justify their inclusion in that form genus. The differences between *T. Scottii* and *Heterangium Grievii* are: Each peripheral loculus of *Telangium* is represented in *Heterotheca* by a series of relatively small loculi; central loculi as well as peripheral ones occur in the new form; the absence of any evidence that the sporangia of *Hetero-*

theca underwent apical dehiscence; the sporangia of *Heterotheca* contain a new form of water storage tracheids; the sporangia of *Heterotheca* retain the twofold cortical sclerotic plates which are characteristic of the cortex of *Heterangium* stem and petiole.—The author regards the last feature as irrefutable evidence of the safe reference of these microsporangia to *Heterangium Grievii*, with which they have invariably been found associated. Although the sporangium has the same claim to the name of the parent plant as either stem or petiole, the author proposes to refer to it under the name of *Heterotheca Grievii*. The anatomical structure of the new sporangia is discussed and illustrated. The author comes to the conclusion that the structure of *Heterotheca Grievii* is strongly confirmatory of the homology of seed and synangium, and is regarded as supplying ample proof of the synangial origin of the seed. She seems to stand in this investigation upon the threshold of the origin of at least one group of Spermatophyta, and she hopes that the conclusions reached cannot fail to have their influence on other groups. This theoretical discussion is made clearer by a series of figures showing transverse sections of various Pteridosperm ovules and pollen sacks.—The author examines carefully the resemblance between *Heterotheca Grievii* and various ovules and microsynangia which are regarded as homologous with it, especially with *Sphaerostoma ovale*. She is convinced that these 2 form genera represent the microsporangium and the ovule of the same species and that the 2 structures are homologous, both being transformation products of a common ancestor. She also believes in the homology of microsporangia and ovules in the case of all the other Lagenostomales, such as *Lagenostoma*, *Conostoma*, and *Physostoma*.—Turning from the Lagenostomales to the Trigonocarpeae, she asks if they bear any internal evidence of origin from such a type of synangium as *Heterotheca*, and concludes that there is a considerable sum of evidence in support of the homology of the Pteridosperm seeds with a microsynangium such as *Heterotheca*.—A. C. Noé.

2559. BERRY, EDWARD W. Tertiary fossil plants from the Republic of Haiti. Proc. U. S. Nation. Mus. 62: 1-10. 1 pl., 1 fig. 1922.—A small Miocene coastal flora from the Republic of Haiti is described. The species *Pisonia conditi* and *Guettarda cookei* are common to the Miocene of the Dominican Republic in the eastern half of the Island, and the following are described as new: *Chara Woodringi*, *Gymnogramme Woodringi*, *Simaruba haitiensis*, *Mespilodaphne hispaniolana*, *Mimusops praeparvafolia*, *Chrysophyllum cahobasensis*, and *Bumelia cuneatafolia*.—E. W. Berry.

2560. BERRY, EDWARD W., and W. A. JOHNSTON. Pleistocene interglacial deposits in the Vancouver Region, British Columbia. Trans. Roy. Soc. Canada (3) 164: 133-139. Pl. 1-2. 1922.—An account is presented of Pleistocene interglacial beds near Vancouver with the identification of the following fossil plants: *Salix Barclayi* Anders (?), *S. myrtilloides* L., *Populus* sp., *Arctostaphylos* sp., *Kalmia glauca* Ait, *Chamaedaphne calyculata* (L) Moen., and *Vaccinium ovalifolium* J. E. Smith.—E. W. Berry.

2561. ENGELHARDT, H. Die Alttertiär Flora von Messel bei Darmstadt. [The early Tertiary flora from Messel near Darmstadt.] Abh. Hess. Landes. 74: 21-128. Pl. 1-40. 1922. This is a posthumous publication, edited by MENZEL, of the veteran paleobotanist of Dresden. A large flora of 359 nominal species is described from Messel in Hesse, with the following composition: 1 fern, 1 cycad, 9 conifers, 12 monocotyledons, 323 dicotyledons, and 13 Phyllites, Carpolithes, and Leguminosites. The facies is intermediate between Eocene and Oligocene and is considered to indicate an upper Eocene age. The abundance of Moraceae, Lauraceae, Apocynaceae, Sapotaceae, Myrtaceae, Celastraceae, Sapindaceae, and Leguminosae give this flora a subtropical character and indicate considerably warmer climatic conditions at the time it flourished than prevail at the present time in corresponding latitudes. The plants show predominating affinities with the existing floras of the East Indies, Australia, Central and South America. The following are the new species: *Podozamites coccaenica*, *Amomum tertiarium*, *Piper europaeum*, *Macropiper rotundifolium*, *Quercus lineari-lanceolata*, *Ficus undulata*, *F. angustifolia*, *F. lauroides*, *F. laurifolioides*, *F. eocaenica*, *F. populifolia*, *F. ovalifolia*, *F. subdimidiata*, *F. ovato-lanceolata*, *F. messelensis*, *F. daphnogenoides*, *F. ovalifolia*, *F. rotundifolia*,

F. orbicularis, *F. callosaeoides*, *Laurelia tertiaria*, *Laurus messelensis*, *L. Friedrichi*, *Persea lanceolata*, *Litsea chattia*, *Sassafras primigenioides*, *S. subdimidiatum*, *Oreodaphne eocaenica*, *Cinchonidium acuminatifolium*, *Morinda tertiaria*, *Ixora tertiaria*, *Notelaea prisca*, *Apocynophyllum ellipticum*, *Echites* ? *tenuifolia*, *Alstonia eocaenica*, *Nerium eocaenicum*, *N. germanicum*, *Neritinium Unger*, *Vitex* ? *pentamera*, *Catalpa Spiegeli*, *Myrsine semiserrulata*, *Maesa europaea*, *Archras protosapota*, *Sapotacites eocaenicus*, *S. Schottleri*, *S. sideroxylenoides*, *Mimusops ballotaoides*, *M. versimilis*, *Chrysophyllum elongatum*, *Diospyros ebenordes*, *Bacca diospyroides*, *Styrax eocaenica*, *S. ovatifolia*, *Gaultheria germanica*, *Hedera pristina*, *Knema tertiaria*, *Magnolia grandifolia*, *M. pristina*, *M. multinervis*, *M. lauriodes*, *Bombax Lepsii*, *Sterculia cinnamomifolia*, *S. grandifolia*, *Pterospermum chatianum*, *P. Steuerei*, *Grewia microcoides*, *G. tenuifolia*, *Tetrapteris messelensis*, *Banisteria tertiaria*, *Sapindus lanceolatus*, *S. firmifolius*, *Thouinia occidentalis*, *Staphylea germanica*, *Celastrus illicinoides*, *Elaeodendron obovatifolium*, *Ptilosporum eocaenicum*, *Pomaderris lanigeroides*, *P. grandifolia*, *Carya hickoryaeformis*, *Rhus ternata*, *R. longifolia*, *Anaphrenium europaeum*, *A. lanceolatum*, *Mangifera tertiaria*, *Melastoma tertiarium*, *Eugenia Heerti*, *Tristania laurinaoides*, *T. tertiaria*, *Callistemon lanceolatum*, *Myrtophyllum incertum*, *M. myrciaefolium*, *Acmena floribundoides*, *Phaseolites eocenica*, *Dolichos* ? *pristina*, *Hardenbergia macrophyloides*, *Machaerium muticoides*, *Cercis grandifolia*, *C. parvifolia*, *Bauhinia europaea*, *Caesalpinia mediocrifoliola*, *Copaifera tenuifolia*, *Leguminosites trigonellaeformis*, *L. cassioides*, *Mimosites Spiegeli*.—E. W. Berry.

2562. PRINCIPI, P. *Flora Messeniana di Polenta in Provincia di Forli*. [Messianian flora of Polenta in the province of Forli.] Riv. Ital. Palaentol. 28: 5-19. Pl. 1. 1922.—The following Mio-Pliocene species are recorded from this locality: *Sequoia Langsdorffii*, *Phragmites oeningensis*, *Carpinus pyramidalis*, *Fagus Antipoffi*, *F. dentata*, *Castanea entymodryis*, *C. Scarbelli*, *C. proteifolia*, *Populus mutabilis*, *Planera Unger*, *Acer controversum*, *Platanus deperdita*, *Terminalia pannonica*, *Cercocarpus Minischalchii*, *Sophora europaea*, *Cassia phaseolites*, *C. Fischeri*. All are well known species of the late Tertiary of Europe.—E. W. Berry.

2563. PRINCIPI, P. *Nuovo contributo allo studio delle Tallofite, Pteridofite, Gimnosperme e Monocotiledoni fossili del giacimento Oligocenico di Santa Giustina e Sassello in Liguria*. [New contribution to the study of the fossil Thallophyta, Pteridophyta, Gymnospermae, and Monocotyledonae of the Oligocene of Santa Giustina and Sassello in Liguria.] Mem. Com. Geol. Ital. 7: 1-90. Pl. 1-7. 1921.—This work completes the description of this extensive and important Oligocene flora, the many dicotyledons from which were described by the same author 2 years previously. The present work treats of 5 algae, 4 fungi, 2 equisetes, 43 ferns, 10 gymnosperms, and 58 monocotyledons from these localities. The specific lines are very finely drawn and often based upon very incomplete specimens. The following are described as new: *Fucus antiquus*, *Equisetum grande*, *Adiantum oligocenicum*, *Pteris protogaea*, *Asplenium Laurenti*, *A. Schimper*, *Aspidium gracile*, *Goniopteris minuta*, *G. Heeri*, *Cyperus antiquus*, *Arecites longus*, *Phoenicites Isseli*, *Palaeospatha deVisianii*, *Palmophyllum Engelhardti*, *Irites grandifolium*.—E. W. Berry.

DISEASES CAUSED BY FUNGI

2564. ANONYMOUS. *Potato trials at Ormskirk*. Nature 110: 431. 1922.—Tests upon 2,500 stocks are being made in 1922 with reference to resistance to wart disease (*Synchytrium endobioticum*). It is evident that rainfall has a considerable effect, the disease appearing earlier and being more pronounced in 1922 than during the dry summer of 1921.—O. A. Stevens.

2565. ANONYMOUS. Root disease of coffee in India. *Tropic. Life* 18: 107. 1922.—The article is a quotation from: ANSTEAD, R. I. Root disease of coffee. *Planters' Chron.* 17: 286-287. 1922.—The disease is caused by *Hymenochaete noxia* Berk. and is said to arise from rotting stumps and roots of dead jungle and shade trees. The fungus, developing on the decaying roots of trees, later enters the living roots of the coffee bushes and causes death or serious impairment. The trees chiefly concerned in producing infection are white cedar, cinnamon, Bassari, Jack, and Atti. Complete removal of the stumps of any of these trees, or others known to act as host for the disease, from fields devoted to coffee production or designed for that purpose, is the remedy suggested. Infected coffee bushes and roots should be removed and burned, and the ground thoroughly limed.—H. N. Vinall.

2566. ANONYMOUS. White-pine blister rust in the western United States. U. S. Dept. Agric. Circ. 226. 7 p., 9 fig. (5 colored). 1922.—“Until very recently our great forests of western white pine (*Pinus monticola*) and sugar pine (*P. lambertiana*) have been free from this disease, *Cronartium ribicola* Fischer, but in the autumn of 1921 the blister rust was found in western British Columbia and the Puget Sound region of Washington.”—L. R. Hesler.

2567. BARSS, H. P. Destructive rust (*Puccinia subnitens* Dietel) on spinach in the Northwest [U. S. A.]. [Abstract.] *Phytopathology* 12: 446. 1922.

2568. BEWLEY, W. F. Anthracnose of the cucumber under glass. *Jour. Ministry Agric. Great Britain* 29: 469-472, 558-562. 1922.—This is now the most important leaf spot disease of the cucumber in Great Britain, causing heavy annual losses. The overwintering and control of the causal organism, *Colletotrichum oligochaetum* Cav., have been studied, and the following conclusions drawn: The fungus “carries on a saprophytic existence in rotten woodwork, timber, paper, etc., in the glass houses, and thus tides over the winter period. Straw manure from towns constitutes an important source of infection. Infected houses may be cleansed by spraying the interior woodwork during the winter with emulsified cresylic acid. The disease may be controlled during the growing season by employing drastic methods of ventilation, or by alternately spraying the plants with liver of sulphur or lime-sulphur and flour paste, and removing the spotted leaves.”—M. B. McKay.

2569. BIRS, P. M. Le Polyporus (*Ungulina*) *Inzengae* De Not., parasite du peuplier. [Polyporus *Inzengae* as a parasite of *Populus*.] *Bull. Soc. Path. Vég. France* 9: 166-168. 1922.—This fungus seems to be a wound parasite, destroying the lignin in wood, and causing the trunks to break easily.—J. Dufrenoy.

2570. BOYCE, J. S. White pine blister rust in the Pacific Northwest [U. S. A.]. [Abstract.] *Phytopathology* 12: 448. 1922.

2571. BROWN, WILLIAM. Studies in the physiology of parasitism. IX. The effect on the germination of fungal spores of volatile substances arising from plant tissues. *Ann. Botany* 36: 285-300. 1922.—The author placed the tissues in large Petri dishes, side by side with clean slides carrying aqueous suspensions of spores,—those of *Botrytis cinerea* proving most convenient. In general the effects were more marked when the leaves or tissues were first bruised. The presence of certain plant tissues, such as apple leaves and the leaves of *Ruta*, *Eucalyptus*, etc., increased spore germination. In other cases there was reduced germination or even inhibition with tissues of potato tuber, onion leaves, or bulb scales. The effect was more easily discernible when the spores were of feeble germinating capacity. Similar stimulating and retarding effects were produced by certain simple chemical substances such as ethyl acetate. A few other fungi behaved as did *Botrytis cinerea*. Experiments proved that the carbon dioxide evolved is not the agent affecting germination. The action is due to volatile substances arising from the tissues. These volatile stimulants were sufficient to increase markedly the parasitic powers of *Botrytis* spores. It was found that the presence for some time of wet blotting paper in the Petri dishes retarded germination; all

results indicated that this was due to some organism or organisms present on the paper. The effect of these results on mycological technique and on problems of parasitism is discussed.—*W. P. Fraser.*

2572. CARLETON, M. A. Note on the fusarium wilt disease of bananas. *Science* 56: 663-664. 1922.—The writer performed inoculation experiments confirming those of E. W. Brandes, who proved that the so called "Panama disease" of bananas is caused by *Fusarium Cubense* EFS.—Plants growing in pots of sterilized soil and inoculated with pure cultures of *Fusarium Cubense* all contracted the disease, while all checks remained healthy.—*C. J. Lyon.*

2573. CHABROLIN, CH. Les dépérissements de l'abricotier dans la vallée du Rhône. [Diseases of apricots in the Rhone Valley.] *Bull. Office Regional Agric. Midi* 1922¹: 24-37. 1922.—This most perplexing disease of apricots consists in a total or partial wilting of the trees, which may occur at any period of the year. The phloem tissues of wilted branches show a conspicuous browning and may be infected by various fungi, a *Cytospora* being chiefly described.—*Coryneum* and *Monilia* are responsible for much loss.—*J. Dufrénoy.*

2574. CHRISTIAN, J., et L. DUCCELLIER. L'ergot de l'avoine en Algérie. [Ergot of oats in Algeria.] *Bull. Agric. Algérie-Maroc Ser. 2*, 28: 121-138. 2 fig. 1922.—This article discusses the spread of ergot of oats in Algeria and its attendant danger; the different modes of propagation of the causal fungus; the presence of ergot infection, which may pass unnoticed; the large number of grasses which may act as possible carriers, since the specialization of this ergot on oats alone is not yet demonstrated; the use of clean seed; incineration of refuse after threshing; elimination of ergot of oats in the seed with saline solutions, and the advisability of this method of treatment in infected regions; and the importance of the destruction of weed grasses in and near oat fields before blossoming time. [See also Bot. Absts. 12, Entry 2579.]-*Frederick V. Rand.*

2575. DARNELL-SMITH, G. P. Fungus and other diseases of stone fruits. *New South Wales Dept. Agric. Farmers Bull.* 133. 23 p., 15 fig. 1920.—Popular descriptions and suggested treatments are given for 4 diseases: peach leaf curl (*Exoascus deformans* (Berk.) Fekl.), brown rot (*Sclerotinia fructigena* (Pers.) Schr.), rust (*Puccinia prunispinosae* Pers.), and peach freckle (*Cladosporium carpophilum* Thüm.). The ascigerous stage of brown rot has not been noticed as occurring in Australia.—*L. R. Waldron.*

2576. ELLIOTT, JOHN A., and R. F. CRAWFORD. The spread of tomato wilt by infected seed. *Phytopathology* 12: 428-434. Pl. 28, fig. 1-2. 1922.—Seed from tomato fruits that were thoroughly invaded by the wilt fungus (*Fusarium Lycopersici* Sacc.) were saved by the usual method and stored for several months. They were then planted on sterile moist filter paper; and all fungi growing from the seed which resembled *F. Lycopersici* were isolated and studied. The final test in all cases was the ability of the isolated fungus to produce tomato wilt. Approximately 3½ per cent of the seed carried the wilt fungus, which in some cases seemed to have entered the seed coat.—*B. B. Higgins.*

2577. FAWCETT, HOWARD S. A new Phomopsis of Citrus in California. *Phytopathology* 12: 419-424. Fig. 1-2. 1922.—A Phomopsis, resembling *P. Citri* Fawcett, has been found causing a stem-end rot of citrus fruits in California packing houses. Comparison of the 2 fungi in culture and in their ability to attack citrus fruits showed such marked differences that the California fungus is considered a distinct species. It is named and described as *Phomopsis californica* n. sp.—*B. B. Higgins.*

2578. F[OËX], E. Dépérissement des ormes (*Ulmus campestris* et autres espèces d'*Ulmus*). [Dying of elms.] [Rev. of: (1) SPIERENBURG, DINA. Een onbekende ziekte in de iepen. [An unknown disease of the elm.] Verslag. en Mededeel. Plantenziek. Wageningen 18: 1-10. 1918. (2) SCHWARZ, M. B. Das Zweigsterben der Ulmen Trauerweiden und

Pfirsichbäume [Twig blight of elms, weeping willows, and peach trees.] Thesis, Univ. of Utrecht. 1922. (3). Guyot. Note de pathologie végétale. [Note on plant pathology.] Bull. Soc. Path. Vég. France 8: 132-136. 1921 (see Bot. Absts. 11, Entry 2955).] Bull. Soc. Path. Vég. France 9: 200-204. 1922.—Since 1918 elms have died in great numbers in France, Belgium, and Holland. The disease is more severe in young trees than in old, and may cause death of whole or parts of trees. Brown spots appear in the wood and the leaves wither. No organism was demonstrated directly in discolored wood, but in culture a *Cephalosporium-Graphium* accompanied by bacteria was obtained. Mlle. Schwarz obtained infections with a pure culture of *Graphium Ulmi* inoculated into either wood or bark.—*Lillian C. Cash.*

2579. F[OËX], E. **L'ergot de l'avoine en Algérie.** [Ergot of oats in Algeria.] [Extract and rev. of: CHRISTIAN, J., et L. DUCELLIER. **L'ergot de l'avoine en Algérie.** Bull. Agric. Algérie-Maroc Ser. 2, 28: 121-138. 2 fig. 1922 (see Bot. Absts. 12, Entry 2574).] Bull. Soc. Path. Vég. France 9: 196-199. 1922.—Ergot can be separated from healthy seed by floating on an 8 per cent solution of nitrate of soda.—*J. Dufrénoy.*

2580. GRINȚESCU, IOAN. **Le noir des blés en Roumanie.** [The brown rust of grain in Rumania.] Bul. Soc. Științe Cluj 1: 292-295. 1921.—The author first observed this disease in Rumania in 1920 when it was sent to him from the vicinity of Bucharest. It was reported from other stations in Rumania especially in Banat the same year. In studying the disease the author found that the plants were attacked by 3 species of fungi, *Cladosporium graminis* Cda., *Alternaria tenuis* Nees, and *Fusarium avenaceum* (Fr.) Sacc. The author is convinced from his experiments that the trouble is due to *Fusarium avenaceum*; the other 2 fungi are saprophytic and have a secondary significance. Inoculations with all 3 forms were negative.—*M. Tiesenhausen.*

2581. GUINIER, P. **La "dorge" ou "chaudron" du sapin.** [The burl or canker of fir.] Bull. Trimest. Soc. Forest. Franche-Comté et Belfort 14: 333-347. 3 pl. 1922.—Canker-like burls are frequent on trunks of *Abies alba* in the Jura Mountains. They may be annular or unilateral, open or closed, dry or rotted. The wood of these growths has a special structure, the annual rings being sinuous and of irregular width; resinous streaks of bark are often included in the reddish wood. The effect on growth is almost negligible, but the value of the wood is reduced because of the loss of $\frac{1}{2}$ -1 m. in the best part of the trunk; the loss in volume is about 5 per cent, in value about 10 per cent. The cankers develop at points where witches' brooms have fallen off. The 2 deformities are caused by successive stages in the development of *Aecidium elatinum*, which has an alternate stage on members of the family Alsineae, *Stellaria nemorum* being the most abundant species in the Jura fir forests. There is no remedy after the canker is formed, but cutting the witches' brooms offers a method of attack for young trees. Fifty per cent of the brooms are less than 7 m. above the ground. The cutting is not expensive, and should be repeated every 5 or 10 years.—*J. Kittredge, Jr.*

2582. HORNE, WM. TITUS. **A Phomopsis in grape fruit from the Isle of Pines, W. I., with notes on *Diplodia natalensis*.** Phytopathology 12: 414-418. Pl. 26-27, fig. 1. 1922.—In a shipment of grape fruit from the Isle of Pines 2 specimens showing a tan colored rot were found. Tissue cultures from one of these gave *Diplodia natalensis*. From the other, cultures of a *Phomopsis* were obtained. Inoculations, made by placing either mycelium or spores of the *Phomopsis* on the calyx or on wounded calyx scars of grape fruits held in moist chambers, produced typical stem-end rot. However, the fungus differed from *Phomopsis Citri* Fawcett, both morphologically and in the growth on culture media, sufficiently to be considered distinct. The name *Phomopsis caribaea* n. sp. is suggested.—*B. B. Higgins.*

2583. HORTON, E., and E. S. SALMON. **The fungicidal properties of certain spray-fluids.** III. Jour. Agric. Sci. 12: 269-279. 1922.—To ensure comparable results similar cuttings from a single hop vine (*Humulus Lupulus* L.) were used, and observations made on leaves of similar age. Inoculations were made with the "powdery" conidial stage of *Sphaerotheca*

Humuli (DC.) Burr. To secure complete wetting of the fungus 1 per cent of calcium caseinate was added to the solutions. One leaf at a node was utilized for the "test," the other serving as control. Disodium arsenate containing 0.096 per cent As_2O_5 proved fungicidal and killed patches of leaf-cells underlying the mildew patches but did not otherwise injure the leaf. A solution containing 0.02 per cent As_2O_5 was fungicidal without killing any leaf-cells. Trisodium arsenate containing 0.077 per cent As_2O_5 and dicalcium arsenate containing 0.048 per cent As_2O_5 also proved fungicidal. Dicalcium arsenate in solution containing 0.024 per cent As_2O_5 proved to be barely fungicidal in its action. Tricalcium arsenate containing 0.076 per cent As_2O_5 is fungicidal and a solution of 0.02 per cent has some value; but a solution with but 0.01 per cent of As_2O_5 is practically non-fungicidal. The following constituents of lime-sulphur wash proved non-fungicidal: calcium sulphate, sulphite, thiosulphate, and hydroxyhydrosulphide. However, calcium polysulphide at a strength of 0.11 per cent proved fungicidal. A bibliography of 20 numbers is included.—V. H. Young.

2584. HUBERT, ERNEST E. A staining method for hyphae of wood-inhabiting fungi. *Phytopathology* 12: 440-441. 1922.

2585. HUNGERFORD, CHAS. W. A fusarium blight of spinach. [Abstract.] *Phytopathology* 12: 447. 1922.

2586. HYDE, KARL C. Anatomy of a gall on *Populus trichocarpa*. *Bot. Gaz.* 74: 186-196. *Pl. 6.* 1922.—This paper is concerned with a lateral stem swelling caused by *Macrophoma tumefaciens* Shear on poplar. The gall structure differs from that of the normal stem in the following respects: the rays are multiseriate instead of uniseriate; the xylem elements are greatly distorted; a marked increase in size and number of cells occurs in the gall bark; the amount of suberized tissue is greatly increased; and an abnormally large number of phloem parenchyma cells are formed. The writer believes that the abnormal xylem is incapable of satisfactorily conducting water and solutes to the stem portion beyond the gall. This accounts for its weakening and death.—B. W. Wells.

2587. JONES, L. R., and W. B. TISDALE. The influence of soil temperature upon the development of flax wilt. *Phytopathology* 12: 409-413. *Fig. 1.* 1922.—The seed of a very susceptible variety of flax were planted in cans of soil infested with *Fusarium Lini* Bolley. The cans were placed in soil temperature tanks held at graduated intervals between 12 and 38°C. The percentage of plants which had wilted at the end of a 24-day period was taken as a basis of comparison. The minimum temperature for the development of the wilt disease was about 14°C., the maximum 38°C., and the optimum between 24 and 28°C. This relation of disease to temperature shows close correlation with the development of the fungus in culture.—B. B. Higgins.

2588. KEMPTON, F. E. Progress of barberry eradication. U. S. Dept. Agric. Dept. Circ. 188. 37 p., 4 fig. 1921.—The relation of barberries and Mahonias to the stem rust situation is summarized. The origin, organization, and methods of the campaign are discussed. The results of the campaign are further summarized by years and by states. In 3 years almost all cities, towns, and villages in the 13 states of the eradication area were surveyed. In the farm-to-farm survey an area which approximates 183 counties was covered in the original survey, but the necessary resurvey was made in only a few of these counties.—L. R. Hesler.

2589. LEONIAN, LEON H. Stem and fruit blight of pepper caused by *Phytophthora Capsici* sp. nov. *Phytopathology* 12: 401-408. *Fig. 1-2.* 1922.—A hitherto unreported disease of pepper (*Capsicum annuum* L.) is described. On the pods soft decayed spots are produced, which soon dry and become leathery. On old parts of the stem brownish lesions are produced, which usually girdle the stem killing the parts beyond; but on younger parts the pathogen passes rapidly through until halted by the older hard tissues. The disease is produced by a new species of *Phytophthora* which is described as *P. Capsici*. The fungus is carried in seed from diseased pods; therefore seed selection and sterilization are recommended as control measures.—B. B. Higgins.

2590. LINK, G. K. K., and F. C. MEIER. Anthracnose of muskmelons. U. S. Dept. Agric. Dept. Circ. 217. 4 p., 1 pl. 1922.—This is a popular account of the disease caused by *Colletotrichum lagenarium* (Pers.) E. & H., including symptoms, nature of losses, environmental influences, and control.—L. R. Hesler.

2591. LINK, G. K. K., and F. C. MEIER. Fusarium tuber rot of potatoes. U. S. Dept. Agric., Dept. Circ. 214. 8 p., 2 pl. 1922.—The nature, symptoms, and control of the disease caused by *Fusarium* sp. are discussed in a popular manner.—L. R. Hesler.

2592. LINK, G. K. K., and F. C. MEIER. Late-blight tuber rot of the potato. U. S. Dept. Agric. Dept. Circ. 220. 5 p., 2 pl. 1922.—The nature of the damage, occurrence, conditions favoring, and the control of the disease caused by *Phytophthora infestans* (Mont.) de Bary are given.—L. R. Hesler.

2593. LINK, G. K. K., and F. C. MEIER. Phoma rot of tomatoes. U. S. Dept. Agric. Dept. Circ. 219. 5 p., 1 pl. 1922.—Phoma blight and rot, caused by *Phoma destructiva* Plowr., occur most frequently in southern winter-grown tomatoes, i.e., in the crops of California, Cuba, Florida, and Mexico. The main source of infection is the soil; the fungus develops on the vegetative portion of the tomato and later attacks the fruit through injuries in the skin, most frequently at the stem end either through growth cracks or the fruit-stem scar. On ripe fruits there appear water-soaked concave spots which rapidly enlarge but remain more or less circular and concave with brown or black, firm, leathery centers dotted with the black fruiting bodies from which are extruded the slimy whitish spore masses. The fungus attacks the leaves, petioles, and stems. Spots on the leaves frequently begin at the margin as small discolored areas which become brown or black, enlarge, and finally merge into a large blotch of definite outline but irregular shape.—Lillian C. Cash.

2594. MCKAY, M. B. *Thielavia basicola* on watermelon in Oregon. [Abstract.] Phytopathology 12: 445. 1922.

2595. McMURPHY, JAMES. Notes on *Synchytrium*. [Abstract.] Phytopathology 12: 442. 1922.

2596. MANEVAL, W. E. Germination of teliospores of rusts at Columbia, Missouri. Phytopathology 12: 471-488. 1922.—The teliospores of several rusts were collected at intervals during the fall, winter, and spring and germinated by floating on the surface of water in covered culture dishes kept at approximately 20°C. The species used in the tests were: *Phragmidium Potentillae-canadensis* Diet.; *Puccinia Asparagi* DC.; *P. Helianthi* Schw.; *P. Menthae* Pers. var. *americana* Burr.; *P. Ruelliae* (B. & Br.) Lagh.; *P. Andropogonis* Schw.; *P. peridermiospora* (Ell. & Tracy) Arth.; *P. Sorghi* Schw.; *P. Sydowiana* Diet.; and *P. Windsoriae* Schw. The teliospores of all germinated in December or earlier. As the season advanced toward spring the percentage of germination increased and the necessary period of incubation decreased.—B. B. Higgins.

2597. MOSS, E. II. Observations on two poplar cankers in Ontario. Phytopathology 12: 425-427. 1922.—A canker, produced by *Dothichiza populea* Sacc. & Briard, was found in a very destructive form on newly planted trees of Lombardy poplar (*Populus nigra* L. var. *italica* Du Roi) at Toronto, Canada. This fungus was also found attacking branches of older trees in various localities in southern Ontario. In the neighborhood of Toronto, also, *Cytospora chrysosperma* (Pers.) Fr. has been found attacking *Populus deltoides*, *P. nigra* L. var. *italica* Du Roi, *P. balsamifera*, *P. alba*, and *Acer saccharinum*.—B. B. Higgins.

2600. POLE EVANS, I. B., and MARY POLE EVANS. Rise in temperature of living plant tissue when infected by parasitic fungus. *Nature* 110: 480-481. 1922.—The writers found a definite rise of temperature in oranges and grape fruit following inoculation with *Penicillium digitatum*. Further account of the experiments is promised.—*O. A. Stevens.*

2601. POOLE, R. FRANK. A new fruit rot of tomatoes. *Bot. Gaz.* 74: 210-214. *Pl.* 7. 1922.—Cracking of green and ripe fruit of certain tomato varieties in New Jersey was found to be caused by *Oidium* or *Oospora lactis*. Inoculations of ripe fruit gave positive results. On the fruit the mycelium is prominent and appears as a dense grayish white layer. Slight control was achieved with Bordeaux sprays and dusts. The fungus is widely distributed, being known also on cheeses and decaying vegetables.—*B. W. Wells.*

2602. RAEDER, J. M. A *Helminthosporium* root rot of wheat in Idaho. [Abstract.] *Phytopathology* 12: 447. 1922.

2603. RAEDER, J. M., and CHAS. W. HUNGERFORD. The effect of presprinkling with water upon the efficiency of certain potato seed treatments for the control of *Rhizoctonia*. [Abstract.] *Phytopathology* 12: 447-448. 1922.

2604. RAMSEY, G. B. *Basisporium gallarum* Moll., a parasite of the tomato. *Bot. Gaz.* 74: 325-328. *Fig.* 1-11. 1922.—This fungus is reported to induce a soft, red, blister-like lesion near the blossom end of ripe tomatoes. Inoculations on wounded fruit "have shown conclusively that the fungus is strongly pathogenic." On unwounded surfaces negative results were obtained. The fungus grows readily on most nutrient agars.—*B. W. Wells.*

2605. RAST, LOY E. Control of cotton wilt by the use of potash fertilizers. *Jour. Amer. Soc. Agron.* 14: 222-224. *Fig.* 1-3. 1922.—In 1920 a 5-acre cotton field on alluvial river land near Scott, Arkansas, was destroyed by wilt. A part of the field had been treated with a fertilizer containing 10 per cent phosphoric acid, 3 per cent nitrogen, and no potash. The following year the same fertilizer was mixed with an equal amount of kainit containing 12.5 per cent potash and applied at the rate of 1,000 pounds per acre. On the unfertilized acre used as a check, 95 per cent of the plants died, whereas in the fertilized field there was no noticeable injury.—*Lillian C. Cash.*

2611. WEBER, GEORGE F. *Septoria* diseases of cereals. *Phytopathology* 12: 449-470. Pl. 29-30, fig. 1-5. 1922.—This is the 1st of a series of 3 papers on this subject. Except for a brief introduction the paper is devoted entirely to a discussion of "speckled blotch" of oats, which has been collected twice near Madison, Wisconsin. It has been known in Europe since 1895, but has not been reported previously from the U. S. A. The disease is produced by *Leptosphaeria avenaria* sp. nov. (= *Septoria Avenae* Frank). Small, circular to elliptical or elongate, dead, faded lesions are produced on the leaves of the oat plant. The dead areas soon become speckled with the black pycnidia of the fungus. The ascigerous stage has not been found on the host plant, but numerous perithecia with mature ascospores have been found in potato-agar and oatmeal-agar cultures obtained from single pycnosporos. The disease has been reproduced by inoculating oat plants with either ascospores or pycnosporos from these cultures. Inoculations were also made on various cultivated and wild grasses but infections were obtained only on species of *Avena*. The morphology and the more important physiological reactions of the fungus are described.—B. B. Higgins.

2612. WHETZEL, H. H. The pink-root of onions. *Agric. Bull. Bermuda Dept. Agric.* 1922: 4-6. July, 1922.—This disease, caused by *Fusarium mali* Allesch., is reported as very severe in Bermuda and is considered the chief factor in the 50 per cent reduction of the onion crop shown by the official records of yields for the past 10 years. A method of control is suggested.—H. H. Whetzel.

2613. WILLAMAN, J. J., and F. R. DAVISON. Biochemistry of plant diseases. IV. Proximate analysis of plums rotted by *Sclerotinia cinerea*. *Bot. Gaz.* 74: 104-109. Fig. 1-2. 1922.—Four varieties of plums in 3 stages of maturity were employed. Determinations were made of the ash content, calcium, nitrogen, ether extract, and crude fiber of sound and rotted fruits, the latter proving higher in ash, CaO, nitrogen, and ether extract than sound ones. Further, resistant varieties were conspicuously higher in crude fiber than susceptible ones, but were lower in ash, CaO, nitrogen, and ether extract. During the process of normal ripening there is a decrease of ash, CaO, and nitrogen content due probably to storage of carbohydrates and acids.—F. A. Wolf.

2614. WINGARD, S. A. Yeast-spot of lima beans. *Phytopathology* 12: 525-532. Fig. 1-4. 1922.—A diseased condition of lima beans (*Phaseolus lunatus* L.), in which dark brown sunken spots are produced on the seed, has been observed in 7 counties of eastern Virginia. In some lots 60 per cent of the seed showed infection. Numerous isolations from diseased tissue gave pure cultures of a yeast. Inoculations made by spraying green uninjured pods with suspensions of the yeast or smearing uninjured pods with pure cultures of the yeast failed to produce infection; but the disease is readily reproduced by pricking the pods with a needle dipped in a pure culture of the yeast. The organism is considered a new species and the name *Nematospora Phaseoli* is proposed. The same or a similar disease has been collected on black eyed pea (*Vigna sinensis* Hassk.).—B. B. Higgins.

2615. WINSTON, JOHN R. Commercial control of citrus scab. U. S. Dept. Agric. Circ. 215. 8 p. 1922.—Important facts on the origin and geographical occurrence, importance, susceptibility, overwintering of the causal fungus, and control are given. The organism is usually but erroneously referred to as *Cladosporium Citri* Massee. Plain Bordeaux mixture as well as Bordeaux-oil emulsion is very effective against scab either in the orchard or nursery. Burgundy and ammoniacal copper carbonate, and lime sulphur are less effective than Bordeaux. Schedules for spraying are given for types of localities with regard to severity of the disease.—L. R. Hesler.

2616. WORMALD, H. Further studies of the 'brown rot' fungi. A shoot-wilt and canker of plum trees caused by *Sclerotinia cinerea*. Ann. Botany 36: 305-320. Pl. 13, 14. 1922.—The attack begins on the leaves soon after they are unfolded. The mycelium extends from the shoots into the twigs causing cankers and gummosis of the diseased tissues. Conidia of *Monilia cinerea* (Bon.) Schröter sometimes develop on the dead leaves in wet summer weather, but not on the cankers till the following winter and spring. Inoculation of the leaves on short shoots with a pure culture of the fungus isolated from cankers resulted in infection of the leaves followed by cankers on the twigs. Inoculated apple blossoms were killed but infection failed to enter the axis of the inflorescence since the other flowers and leaves of the same shoot remained healthy. The fungus causing the wilt was determined as *Sclerotinia cinerea* (Bon.) Schröter, forma *Pruni*. This determination was supported by the slow rate of secretion of an oxidase when compared with forma *Mali*. The wilt is compared with wither-tip caused by the same fungus. The direct loss due to this wilt is small, but the cankers may prove a source of infection for the next season.—W. P. Fraser.

2617. ZELLER, S. M. A "plum pocket" on *Prunus subcordata* in Oregon. [Abstract.] Phytopathology 12: 443. 1922.

DISEASES CAUSED BY BACTERIA

2618. FROMME, F. D., and S. A. WINGARD. Blackfire or angular-leafspot of tobacco. Virginia Agric. Exp. Sta. Tech. Bull. 25. 43 p., 2 pl., 18 fig. 1922.—Following a discussion of the history, range, and economic importance of blackfire (*Bacterium angulatum*) the authors compare symptoms on seedlings and field plants with those of wildfire and other leafspots of tobacco. Laboratory and field experiments and observations on dissemination, development of infection, and control are described. The occurrence of blackfire in the field is determined largely by the occurrence of infection in the plantbed. The pathogen may overwinter on seed, on plantbed cloth, in tobacco refuse, on plants which do not winterkill, and to a slight extent in soil, especially where refuse from the tobacco crop remains on the surface over winter. Severity of infection is modified by rainfall and host nutrition. Rainfall is the chief agency of dissemination and excessive rainfall predisposes the plant to infection by inducing a vigorous, succulent growth. Host nutrition as modified by fertilizers or topping determines severity of infection to a marked degree. Hence, those plants which make the most rapid, succulent, vigorous growth are most subject to severe injury. Contrary to popular belief deficiency in important fertilizer constituents does not predispose plants to severe infection. Apparently all varieties of tobacco grown in Virginia are sufficiently susceptible so that relief through choice of varieties or selection of resistant strains does not seem probable. Complete disinfection of naturally contaminated seed was obtained with a 15-minute soaking in 1:16 formaldehyde and also with a 10-minute soaking in 1:1000 mercuric chloride. The latter material is preferred because of lack of seed injury. Seed disinfection should be accompanied by plantbed and field sanitation.—F. D. Fromme.

2619. HIGGINS, B. B. The bacterial spot of pepper. Phytopathology 12: 501-516. Pl. 31-32, fig. 1-5. 1922.—The leaves, stems, and fruits of *Capsicum annuum* L. are attacked by a species of *Bacterium*. On the leaves small, pimple-like swellings appear after an incubation period of 10-15 days. These swollen areas soon collapse and die, forming small, circular spots. On stems and fruits small, wart-like lesions are produced. The causal organism is left undetermined. It is very similar to *B. vesicatorium* Doidge and *B. crinitum* Gardner and Hendrick, which cause similar diseases of tomatoes; but it appears to differ from published descriptions of these 2 organisms in certain physiological reactions. The bacteria are carried on the surface of the seed from diseased pods. Seed treatment gives promise of controlling the disease.—B. B. Higgins.

2620. JONES, S. G. A bacterial disease of turnip (*Brassica napus*). Jour. Agric. Sci. 12: 292-305. Pl. 3. 1922.—A disease of root crops in North Wales was found to be prone to appear on soils which had been limed or heavily treated with nitrogenous fertilizers. Casual exami-

nation of a crop of white turnips did not reveal unusual symptoms but closer examination showed the destruction of the young tender leaves of the crown and a flask-shaped, soft, putrid core surrounded by a brown zone abutting on the healthy tissue. In many cases several secondary crowns had taken the place of the original destroyed crown. Farmers reported that earlier stages were seen when the foliage was apparently dead, and that recovery later took place. A rod-shaped organism $1.3-3 \times 0.75-0.9 \mu$ with a single polar flagellum was regularly associated with the disease and its pathogenicity was established by appropriate inoculation experiments. The organism was found capable of producing a soft rot in swede, potato, carrot, radish, and cabbage, but no growth occurred on beetroot. Pectinase and diastatic and peptonizing ferments are produced and the medium in which the organism has grown is capable of disintegrating turnip tissue. While the organism has many characters in common with *Pseudomonas campestris* Smith and *Bacillus Oleracea* Harrison, it is clearly more nearly related to *Pseudomonas destructans* Potter and is considered by the author to be a varietal form of the latter.—V. H. Young.

2621. MEIER, F. C., and G. K. K. LINK. Bacterial spot of cucumbers. U. S. Dept. Agric. Dept. Circ. 234. 5 p., 1 pl. 1922.—This is a popular discussion of the disease caused by *Bacterium lachrymans* Smith & Bryan. The symptoms, nature of losses, geographic occurrence, environmental influences, and control are treated.—L. R. Hesler.

2622. OLSON, GEORGE A. Agricultural gypsum for control of potato scab. Potato Mag. 53: 7, 23. 1 fig. 1922.—Application of 800-1,000 pounds per acre at plowing time has eliminated scab (*Actinomyces chromogenus*) and increased the yield rate in California.—Donald Folsom.

2623. SNOW, LAETITIA M. A new host for the fire blight organism, *Bacillus amylovorus*. Phytopathology 12: 517-524. 1922.—Bacteria were isolated from blighted twigs of the flowering plum (*Prunus triloba* var. *plena*). Cultures from 2 such isolations were compared with a stock culture of the fire blight organism (*Bacillus amylovorus*) and with 1 isolated from blighted crab apple twigs. The cultures showed minor differences in physiological reactions and in pathogenicity; but in general they agreed with published descriptions of *B. amylovorus*. A rather extensive historical discussion and a bibliography are given.—B. B. Higgins.

2624. WOLF, F. A. Wildfire of tobacco. North Carolina Agric. Exp. Sta. Bull. 246. 27 p., 7 fig. 1922.—This investigation is concerned with leafspot disease of tobacco called "wildfire" which was first definitely recognized in North Carolina in June, 1917. It has subsequently been found in 26 counties within the State. It is now known to occur also in Virginia, South Carolina, Georgia, Florida, Tennessee, Kentucky, Ohio, Wisconsin, Pennsylvania, Maryland, Massachusetts, Connecticut, Vermont, and in several districts in South Africa.—Wildfire appears to come suddenly and may render the crop practically worthless. It produces characteristic leaf spots of which the most constant and dependable character in all stages of development is the wide, yellowish border or halo. Seed pods are also affected.—Wildfire is a specific infection and the organism which causes it has been named *Bacterium tabacum*. This has been proved by repeated isolation from diseased tissues and by infection of healthy tobacco with the germ in pure culture. *B. tabacum* is not known to be actively parasitic on any other crop.—The disease originates in the plant-bed. Such agencies as infected seed, contaminated plant-bed covers, infested soil, and man are responsible for the introduction of wildfire into the plant-beds. It is carried to the field at time of transplanting by the use of diseased seedlings.—Moisture is essential not only for infection, but for the dissemination of the disease. Rainy weather, especially when accompanied by wind, favors the rapid spread of wildfire; new infections do not appear in dry periods. Nutritional factors also influence the progress of wildfire.—The only practical method of control centers around the growing of healthy seedlings. If the seed-beds can be kept free from disease, the fields will be free from it also. Prevention of wildfire in the plant-bed depends primarily upon the use of (1) disease-free seed or seed which has been disinfected, (2) new plant-bed cloths or sterilized old ones, and (3) new plant-beds or thoroughly fired old ones. No satisfactory means of checking the disease in the field is known.—F. A. Wolf.

DISEASES CAUSED BY ANIMAL PARASITES (INSECTS, NEMAS, PROTOZOANS, ETC.)

2625. ANONYMOUS. Gulerods-Krusesyge. [Carrot "Krusesyge."] Tidsskr. Planteavl. 28: 62-64. Fig. 1-3. 1922.—This is a discussion of a disease of carrots caused by an insect, *Trioxa viridula*. Spraying with tobacco extract and petroleum emulsion has given good results.—Albert A. Hansen.

2626. ANDREWS, E. A. Some notes on attempts to produce immunity from insect attack on tea. Rept. Proc. Fourth [Pusa] Entomol. Meeting p. 56-59. Calcutta, 1921.—The author makes the following statement based on experience and observation: ". . . comparative immunity from *Helopeltis* attack not only can, but does, occur in nature. In our attempts to produce immunity, we are attempting to discover and reproduce the conditions under which this immunity occurs in nature. The conditions affecting the question are considerably complicated, but would appear to be bound up with the relative proportions of potash and phosphoric acid taken up from the soil by the plant." Analyses of leaves from bushes which in nature were throwing off the disease showed a 4 to 1 ratio of potash and phosphoric acid; the normal ratio is 2 to 1. It thus seems plain to the author that the throwing off of the insect pest is related to a distinct increase in the potash ratio. In direct experiments the only substance producing increased resistance was potash. Attempts to increase liability to attack appear to have failed. No increase in resistance followed in tests with phosphates.—"Mosquito blight" is the name commonly applied to *Helopeltis* injuries.—Frederick V. Rand.

2627. BALLARD, E. Results of investigation of bionomics of *Platyedra gossypiella* Saunders, in South India, together with some notes on *Earias insulana* and *E. fabia*. Rept. Proc. Fourth [Pusa] Entomol. Meeting p. 70-83. Calcutta, 1921.—Damage by the pink boll-worm includes (1) destruction of the seed, (2) retarded development and weakening of the lint, (3) premature opening of the boll leading to invasion by saprophytic fungi, *Nigrosporum*, and others, (4) staining of the lint both in the boll and in the gin, and (5) lowering of germination in unattacked seeds of injured bolls.—Life history studies, amount of damage caused, and control by natural enemies and artificial means are discussed.—Frederick V. Rand.

2628. DUFRÉNOY, J. Tumeurs chancreuses du pin maritime. [Stem tumors of *Pinus maritima*.] Rev. Zool. Agric. et Appl. Coloniale 21: 25-28. Fig. 11-13. 1922.—The wood tissues and medullary rays in tumors due to the injury of the cambium by larvae of *Dioryctria sylvestrella* may become infected by a sterile mycelium.—J. Dufrénoy.

2629. FEYTAUD, J. Le Doryphore. Chrysomèle nuisible à la pomme de terre. (*Leptinotarsa decemlineata* Say.) [The Colorado potato beetle.] Rev. Zool. Agric. Bordeaux 21: 121-168. Fig. 27-39. 1922.—The paper gives a description of the insect, its biology, food plants and damage done, means of dissemination, environmental conditions favorable and unfavorable to it, its distribution in America and in Europe, and its control.—Arsenicals should not be added to Bordeaux mixtures when spraying for this insect as the compound spray has a repellent action. The beetles should be poisoned but not driven away to other fields.—J. Dufrénoy.

2630. FRANÇA, CARLOS. Encore quelques considérations sur la flagellose des Euphorbes. [Some further observations on flagellosis of *Euphorbia*.] Bull. Soc. Path. Exotique 15: 166-168. 1922.—The writer maintains his previous position that *Stenocephalus* is the primary host of *Leptomonas davidi*, the complete proof of which has been doubted by Franchini. He bases his claim on the fact that he has followed the developmental stages of the flagellate in this host. He has been able to see *Stenocephalus*, coming from its hibernation in April and possessing the small salivary forms, easily infect *Euphorbia*, while infection by means of the latex, itself abundantly parasitized, more frequently fails. His position is further strengthened by the coincidence in Switzerland of infection of *Euphorbia* and infected *Stenocephalus* reported by Galli-Valerio.—The writer mentions as well the analogy between the developmental cycles of *Leptomonas donovani*, discovered by Mrs. Helen Adie in the insect *Cimex*

lectularius, in India, and *Leptomonas davidi* Lafont in *Stenocephalus*. The former is a case of the alternate hosts, Hemiptera and vertebrate; the latter, of Hemiptera and phanerogam. The developmental stages of the parasite are practically the same. Attention is called to the appearance of small local lesions at points of inoculation in both cases, the former in connection with the disease Kala-Azar, and the latter with the flagellosis of Euphorbiaceae. [See also Bot. Absts. 12, Entry 2634.]-G. H. Godfrey.

2631. FRANCHINI, G. Amibes et autres protozoaires de plantes à latex du Muséum de Paris (Note préliminaire). [Amoebae and other protozoa of latex bearing plants at the Paris Museum.] Bull. Soc. Path. Exotique 15: 197-203. 1922.—The writer has pursued his work on the organisms of latex-bearing plants and reports several new Euphorbiaceous hosts, as follows: *Elaeophorbium drupifera* and *Euphorbia calyculata* carried trypanosomes similar to those reported in *E. nereifolia* and *E. virosa*, except that they are smaller and the blepharoplast is more often round instead of rod shaped. Some rare forms with 2 nuclei seemed to be in process of division, and some "U" forms were observed. The latex of *E. calyculata* is less thick than that of the others and this permitted the better observation of amoeboid movements. *Excoccaria emarginata* carried a trypanosome that was generally larger than the others, measuring $10-15 \times 3.5-4 \mu$, with several masses of chromatin in the protoplasm. The flagella were not observed clearly. Degeneration forms were seen. Amoebae were observed among the trypanosomes in all 3 species. In *Euphorbia verticillata* there were no trypanosomes but amoebae alone, which were round, and $10-12 \mu$ in diameter. *Manihot dichotoma* harbored small parasites similar to *Leishmania*. The examination of 8 other *Euphorbia* species gave negative results.—In the family Apocynaceae about 30 species were examined. Amoebae were abundant especially in 4 species of *Strophantus*, and in *Acokanthera*, *Thevetia*, and *Cerbera Odollam*. *Herpetomonas* was found in the last, along with the amoebae. In the amoebae of the Apocynaceae, the protoplasm is thick and sometimes the ectoplasm is well differentiated from the endoplasm. The nuclei vary in number from 1 to 8 or more. The amoebae measured from 6 to 20μ in diameter, or if oval, $15-25 \times 6-10 \mu$. *Caudranium javanensis* harbored very numerous protozoa with accentuated amoeboid movements. They had the appearance of large trypanosomes without flagella. Each had 1 or 2 nuclei which stained a clear blue by the Giemsa method, and a curved centrosome staining very dark. The plant was in poor condition,—yellow, and with very little latex.—In the Asclepiadaceae, *Chlorocodon Whitei* harbored small amoebae, and *Cryptostegia grandiflora* contained numerous amoebae of all kinds and dimensions, including typical Crithidian forms. The very large forms measured $30-40 \times 20-30 \mu$.—In the Urticaceae several plants of *Ficus* were examined and about a quarter showed amoebae with fine protoplasm. In *Ficus Benjamina* were numerous amoebae and small trypanosomes similar to those of *Euphorbia*. In *Ficus Pierrei* were numerous undetermined amoebae and other parasites. In *F. Tholloni*, which was about half dried up, amoebae and both elongate and leishmaniform parasites without flagella were found. In *F. carica*, a large tree in the open, there occurred a large amoeba which was cultured in Nöller's solid medium. It is probable that this organism overwinters within the tree, since it was found early in March.—In the Artocarpoideae, amoebae in *Antiaris toxicaria* and in *Lakoocha artocarpus* were generally large and mobile, with many vacuoles and no distinction between ectoplasm and endoplasm.—In the Sapotaceae *Labramia Bojeri*, *Tregulia Africana*, and different species of *Chrisophyllon* and *Mimusops* harbored parasites like those in the Artocarpoideae. In *Sideroxylon inerme*, along with the amoebae, were flagellates of the *Herpetomonas* type. In other species of *Mimusops* were both flagellate forms and large trypanosome-like parasites without flagella.—In the Menispermaceae *Stephania rotunda* var. *succirubra* showed small round and oval parasites. In the Anacardiaceae *Onocarpus viliensis* showed a small protozoon with 1 or several nuclei. In the Passifloraceae different species of *Carica* gave negative results.—Some of the above plants, especially the more infected, were yellowish and with little latex. Certain species of *Ficus* were in bad condition.—Bits of young branches were fixed in Brazil fluid and stained with thionin and with iron haematoxylin. In the latex vessels were round, oval, or elongate bodies with one or several nuclei, black granules in the protoplasm, and sometimes vacuoles. Some oval forms had rather long flagella. These

studies are being continued.—Culturing fresh latex of *Strophantus Rigali* and *S. scandens* on plates of Nöller's medium (blood gelatin) at 24°C., the author secured a thin grayish growth. This consisted in part of amoebae which were mobile and generally smaller than those in the latex. A transfer gave a very rich culture. Some of the organisms showed red corpuscles in different stages of digestion. Cultures were also obtained with the latex of *Antiaris toxicaria*.—Many of the organisms mentioned in the paper are as yet undescribed. The author considers it necessary to study more of the insects inhabiting the plants, and is directing his studies to certain mosquitoes and large flies (*Lucilia* and *Sarcophaga*). It is hardly possible that *Stenocephalus* (mentioned by França) exists in the conservatory of the Botanical Garden of Paris. The author notes a resemblance between the organisms reported by Adie in *Cimex lectularius* and the latex forms.—G. H. Godfrey.

2632. FRANCHINI, G. Flagellose du chou et des punaises du chou. [Flagellosis of cabbage and cabbage bugs.] Bull. Soc. Path. Exotique 15: 163-165. Fig. 1. 1922.—Cabbage-infesting insects of the family Pentatomidae, principally *Pentatoma ornatum*, *P. ornatum* var. *pectorale*, *P. oleraceum*, and *Aelia acuminata*, collected near Bologna, were examined and all but the last found to harbor in their digestive tracts and more rarely in their salivary glands the flagellates *Crithidia* and *Herpetomonas*. The feces of the insects were rich in flagellates and in leishmaniform cysts. Their larvae were also infested. A large quantity of cabbage was examined and the leaves upon which the insects were most abundant were turning yellow and dying. There was no doubt but that the insects were harmful to the plants. Diseased leaves were washed with distilled water and weak alcohol, and smears made from the expressed juice showed not infrequently the presence of flagellates of the *Herpetomonas* type. The flagella, rather long, arose in the centrosome which was generally removed from the nucleus, though sometimes adjoining it or even behind it. There were also present irregular forms, such as those minus the flagella, leishmaniform bodies, helicoidal bodies arranged in groups, small slender ones with or without centrosomes, and even encysted forms. The flagellate forms measured 7-15 or even $22 \times 1-1.5 \mu$, flagella generally very long; leishmaniform bodies, oval, $2-6 \times 1-2 \mu$, or when round $2-3 \mu$ in diameter; cysts were $2-3 \mu$ in diameter, or $2 \times 1.5 \mu$. The writer states that it was necessary to wash leaves thoroughly to rid them of superficial forms which he found undoubtedly expelled with the excreta of the insects. He was not able to find in diseased leaves the organism *Pseudomonas campestris* (Pam.) EFS associated with a similar disease called "black nerve of cabbage."—Flagellosis of the cabbage bugs is frequent, that of the cabbage much rarer. The parasite probably penetrates through insect punctures. [See also Bot. Absts. 12, Entry 2646.]-G. H. Godfrey.

2633. FRANCHINI, G. Nouvelles recherches sur les trypanosomes des Euphorbes et sur leur culture. [New researches on the trypanosomes of Euphorbias, and on their culture.] Bull. Soc. Path. Exotique 15: 299-303. 1 fig. 1922.—The author, continuing his researches on the protozoa of the latex of Euphorbiaceae and other families, enlarges upon previously mentioned facts, including the finding of very large amoeba-like forms in addition to trypanosomes in *Euphorbia nercifolia*. The trypanosomes, especially the smaller ones, were very mobile, with amoeboid movements. Cultures on plates of Nöller's medium (blood gelatin) permitted observations of all stages of development; these confirmed the previous supposition of intermediate developmental stages between the amoebae and the trypanosomes. The small amoeboid forms increase in volume, the protoplasm becomes differentiated, and as they increase in size the U shape is assumed, sometimes with a thin membrane between the 2 parts. Sometimes this thin vacuolate membrane escapes and the larger amoeboid forms appear. Thus all the different forms were observed in the culture. In some, phagocytosis of the red blood corpuscles was evident. In stained mounts from cultures all the different stages were seen. There were resting stages with large vacuoles and round or oval encysted forms. More rarely the very large trypanosomes occurred. Large forms containing numerous small trypanosomes were also seen. These have already been observed in nature and probably represent an endocellular stage of the parasite. Histological studies of sections of young branches and leaves of *Excoccaria emarginata* apparently confirm this point of view. Tryp-

anosomes occurred in the interior of the host cells, sometimes joined to the nucleus. Their development in host tissues appears quite similar to that in culture. Tube cultures were made from an undetermined *Euphorbia* by inoculating directly from the latex to the condensation liquid of Yoshida medium. Likewise, transfers from plate cultures of the organism from *Ficus carica* on Nöller's medium were made to large Yoshida tubes, good growth secured, and further transfers made. Several stages were observed in these cultures also, this being the 1st time that cultures from this host have given a trypanosome stage similar to that from the Euphorbiaceae.—*G. H. Godfrey.*

2634. FRANCHINI, G. Remarques à propos de la note de M. França sur la flagellose des Euphorbes. [Remarks in connection with the note of M. França on flagellosis of the Euphorbias.] Bull. Soc. Path. Exotique 15: 205-207. 1922.—The writer repeats that while he does not dispute the statement that in Portugal *Stenocephalus agilis* may transmit the flagellosis of Euphorbias, he does not consider the transmission of the disease to be limited to that insect. He cites the work of others in support of his contention and gives other evidence in the form of measurements of the parasites, staining reactions, etc. França's conclusion that in Switzerland the disease of the Euphorbias is transmitted by *Stenocephalus* is considered not established till further proof is available. [See also Bot. Absts. 12, Entries 2630, 2647.]—*G. H. Godfrey.*

2635. FRANCHINI, G. Sur une amibe des figuiers de plein air de la région parisienne et sa culture. [On an amoeba of figs growing in the open near Paris, and its culture.] Bull. Soc. Path. Exotique 15: 287-292. Fig. 1-3. 1922.—The parasites were very abundant in the latex, some having amoeboid movements. In preparations fixed with osmic acid, alcohol-ether, and Schaudinn or Brazil fluid, the organisms were somewhat irregular, as were the various other latex organisms previously studied. The round ones were 12-20 μ or more in diameter; the oval, 18-22 \times 12-13 μ ; more elongate forms were 22-28 \times 2-5 μ . The protoplasm was thick, and stained deeply with Giemsa or iron haematoxylin. The nucleus possessed a centriole. From 2 to 18 nuclei were observed in different individuals. The organism did not grow on ordinary culture media, but on Nöller's blood gelatin cultures developed within the medium but not on the surface. In 3 days growth was evident, and in 10-15 days the cultures were well developed, with very numerous amoebae. Frequent transfers were necessary, since the organism grew better on fresh media. In general the amoebae of the cultures were smaller than those of the latex. All stages of multiplication were found. Encysted forms appeared very early. Protoplasmic movement is abundant in culture; only rarely do pseudopodia occur. The organism does not live so well in contaminated cultures. Blocks of gelatin with good growth were fixed in Brazil fluid and imbedded in paraffin; results are not reported. Certain amoebae digested numerous red corpuscles; no ingested bacteria were observed. The organism is very resistant to cold, and overwinters in the interior of the trees. The organism possesses a flagellate stage, which recalls the previously reported transition stages between amoebae and trypanosomes in Asclepiadaceae, Apocynaceae, etc. As to the penetration of the amoebae into the latex of the figs, 2 hypotheses were advanced: (1) penetration from the soil through lesions in the bark, or even through the roots, (2) inoculation by an insect; the latter is the more probable.—*G. H. Godfrey.*

2636. FRANCHINI, G. Sur un flagelle de Lygaeide (*Crithidia oxycareni* n. sp.). [On a flagellate of the Lygaeidae (*Crithidia oxycareni* n. sp.).] Bull. Soc. Path. Exotique 15: 113-116. Fig. 1. 1922.—The insects (*Oxycarenius lavaterae*) were very numerous on a malvaceous shrub, *Althaea syriaca*. They harbored numerous flagellates of the type *Crithidia* in their digestive tubes and more rarely in their salivary glands and probosces. The activities of the organism and its flagellum are described somewhat in detail. Its protoplasm is granular; the large, roundish nucleus is generally in the middle and the blepharoplast usually some distance from it. In the membrane of 50 per cent of the flagellates, in front of the centrosome, is a clear roundish or oval, feebly colored space (vacuole?); the blepharoplast is only exceptionally placed in the middle of this space; the flagellum traverses it or passes over

the outer edge. Rhizoplasts, axostyles, or other special bodies were not observed in the protoplasm. Division is longitudinal, beginning with the flagellum, followed by the blepharoplast, and finally the nucleus. The dimensions of the elongate forms were $26-32 \times 1.5 \mu$, free flagellum $4-6 \mu$ long; of the medium forms, $17-24 \times 1-2 \mu$; of the division forms, $10-17 \times 2-3 \mu$; of the large forms without free flagellum, oval, $9 \times 5.5 \mu$, or roundish, $5-6 \mu$ in diameter; and of the small leishmaniform individuals, $2 \times 1 \mu$, or round ones, 1.5μ in diameter. Many irregularities occur. Some resemble trypanosomes but the blepharoplast is never posterior. The culture of the parasite was never very difficult, the flagellates being very numerous and almost in pure culture in certain insects. On Nöller's medium, after 12-15 days at $25-30^{\circ}\text{C}$. there appeared a light grayish scum formed of numerous flagellates mixed with bacteria. After 4 transfers, pure cultures were obtained. Stained preparations show the Crithidia forms to be smaller than when in the intestines of the insect, and less abundant; there occur a large proportion of slightly elongated, leishmaniform, round, or oval forms.—An inoculation was made into a white mouse with organisms taken directly from the digestive tract of an insect, and the mouse, which became very sick, was killed after 24 days. The parasites were to be found in the blood and in various organs.—Studies were made of the leaves, fruits, and bark of *Althaea syriaca*, and the more rounded forms of the parasite were found. Stained smears from the expressed juice of leaves and peels of the fruits likewise showed these forms. Reddish spots were noted on the leaves and bark in connection with deposits of feces of the insects, and it is considered probable that these deposits were the source of infection. The elongate or flagellate forms, less resistant to external agents, disappeared, while the roundish and encysted forms, more resistant to the action of the sun, etc., survived.—G. H. Godfrey.

2637. FRANCHINI, G. Sur un flagellé nouveau du latex de deux Apocynées. [On a new flagellate of the latex of two Apocynaceae.] Bull. Soc. Path. Exotique 15: 109-113. Fig. 1. 1922.—In 1 of 4 plants of *Funtumia* examined a protozoon was found in the latex of the trunk, the young branches, and the leaves. It was not present in the roots. Specimens were fixed with alcohol-ether, and stained by the "Giemsa" and iron haematoxylin methods. The protozoon was elongate, without flagella or with very short flagellum; nucleus, median, spherical, and often surrounded by a lightly stained, clear zone; blepharoplast, anterior; rarely a rhizoplast. The flagellum arising in the blepharoplast was usually very short, but sometimes longer than the parasite. Besides the elongate or flagellate forms there were roundish or oval forms with different dimensions, sometimes with several chromatic masses in the protoplasm. Some very much elongate division forms with 2 nuclei and 2 centrosomes occur, with a constriction in the middle and the centrosomes toward the center, near the constriction. Some large forms with pale protoplasm, several chromatic masses, and vacuoles, were probably degenerating. Others with thick walls, with nucleus and without centrosome, were encysted. Elongate forms were $7-18 \mu$ long by $1.5-2 \mu$ wide; flagella $3-15 \mu$ long. Small roundish forms were $3-4.5 \mu$ in diameter, or $5 \times 4-4.5 \mu$. Large forms were $8-10 \times 5-6 \mu$, or (roundish) $5-6 \mu$ in diameter.—In addition, special cells enclosed from 2 to 3 or more forms similar to but smaller than those that were free. The cells were $7-15 \mu$ long and $4-10 \mu$ wide.—In *Thevetia nereifolia*, growing in close proximity to the *Funtumia* at Florence, Italy, a protozoon occurred which was similar to those described in the latter. The flagella were not seen, however, and the elongate forms were more rare. This plant was less parasitized than the other. It is probable that the same insect inoculated both hosts with the parasite. The protozoon probably belongs to *Herpetomonas* or a closely related genus. The 2 parasitized plants do not seem to suffer from infection, though some time earlier 2 plants died in an unexplained manner.—G. H. Godfrey.

2638. FRANCHINI, G. Sur un trypanosome du latex de deux espèces d'Euphorbe. [On a trypanosome of the latex of two species of Euphorbia.] Bull. Soc. Path. Exotique 15: 18-23. Fig. 1. 1922.—Organisms were found in the latex of 2 species of *Euphorbia* growing in the botanical garden at Florence (Italy). These organisms were sometimes round and sometimes oval or elongated, with a nucleus and granulations in the protoplasm and without flagella.

In addition, true trypanosomes and a series of other forms were found. It was not possible to study their mobility, since the latex quickly coagulated on exposure to the air. Two types of trypanosomes, large and small, were studied, the former measuring $8-10 \times 1-2 \mu$, the latter $4-8 \times 1-1.5 \mu$. The nucleus was round and generally toward the forward part of the body. The blepharoplast was posterior to the nucleus. The stages of development, shown in the figure, resemble those of *Trypanosoma Cruzi* or of *Cystotrypanosoma intestinalis*, the latter found in a fly. This trypanosome is similar to those described in a number of insects and vertebrates. It appears to be distinct, however, and is named *Trypanosoma Euphorbiae*. In connection with its transmission, a large number of insects were studied. Certain obligate phytophagous insects, which are named, found associated with the 2 species of *Euphorbia*, contained *Herpetomonas* and *Crithidia*, but no trypanosomes. França in Portugal attributes transmission of flagellosis of the Euphorbias to *Stenocephalus agilis*, since he has seen this insect on the Euphorbias and has found flagellates in its intestine, glands, and proboscis. It is probable that in Italy other insects transmit the disease. Certain non-phytophagous or only occasionally phytophagous insects such as flies and mosquitoes often deposit their feces on the leaves, stems, branches, etc. The feces are often rich in flagellates and encysted forms. Some of these forms harbored trypanosomes in addition to *Herpetomonas* and *Crithidia*.—*G. H. Godfrey*.

2639. GHOSH, C. C. **Supplementary observations on borers in sugar-cane, rice, etc.** Rept. Proc. Fourth [Pusa] Entomol. Meeting, p. 105-136. Calcutta, 1921.—A large number of species of termites, mole crickets, beetle grubs, beetles, red ants, etc., are discussed in relation to habits and life-histories, amount and character of damage caused, and control.—“Apart from their capacity to cause damage directly, the beetles and beetle grubs and in fact all the external agents of damage are responsible for probably much greater damage indirectly by affording places for entry of fungal diseases through bites on the surface of the stems.” In most cases the direct injury consists in boring into or chewing plant parts. In the case of *Pachydiplosis oryzae*, however, the larvae of this small mosquito-like fly feed inside of rice plants and cause the growth of a long, tube-like gall in place of the stem. Affected stems produce no ears.—*Frederick V. Rand*.

2640. HUSAIN, M. AFZOL, and HEM SINGH PRUTHI. **Preliminary note on winter spraying against mango hopper (*Idiocerus* spp.), vernacular name Tela.** Rept. Proc. Fourth [Pusa] Entomol. Meeting p. 148. Calcutta, 1921.—Hoppers that survive the winter move out in early spring from under the bark and cluster on the floral buds where they remain sucking the sap during the growth of the inflorescence. The nymphs, occurring in enormous numbers, are most injurious to the flowers, causing them to shrivel, brown, and finally fall. The attacked inflorescence has a blighted appearance which in severe cases can be seen from a distance. Honeydew falling on the blossoms also causes damage and renders pollination more difficult.—The flowers are too delicate to withstand spray treatment, but winter spraying in the early morning when the hoppers are sluggish will greatly reduce their numbers.—*Frederick V. Rand*.

2641. JHAVERI, T. N. **Notes on cotton wooly mite (*Eriophyes gossypii*).** Rept. Proc. Fourth [Pusa] Entomol. Meeting p. 96-97. Calcutta, 1921.—In the vernacular the disease is known as *chhasia* on account of the ash-like appearance of affected leaves. In years of drought it spreads over wide areas greatly checking the growth of the cotton plant. Affected leaves remain small and curl upward. Checking of the disease in December and January is apparently brought about by the heavy dews of winter. The mites responsible for this disease live mostly under the epidermis of the leaf and cause a dense growth of hairs on both surfaces and on the stem. At an advanced stage of the crop tiny predatory grubs of Coccinellid beetles attack the mites and greatly reduce their numbers. Artificial control is also discussed.—*Frederick V. Rand*.

2642. McCracken, Isabel, and Dorothy Egbert. California gall-making Cynipidae with descriptions of new species. Stanford Univ. Publ. Ser. Biol. Sci. 3¹: 1-70. 2 pl. 1922.—Following the 3 introductory pages on the biology of gall-making Cynipidae and of non-gall makers, or Inquilines, the authors give, under each of the 113 species discussed, a brief description of the galls produced and references to type specimens, hosts, and type localities. Where new species are considered descriptions are included. The various species and their hosts are also shown graphically in 2 tables.—*Frederick V. Rand.*

2643. McKay, M. B. Distribution of *Tylenchus dipsaci* on wild strawberry in Oregon. Preliminary report. [Abstract.] Phytopathology 12: 445-446. 1922.

2644. McWhorter, Frank P. The nature of the organism found in the Fiji galls of sugar cane. Philippine Agric. 11: 103-111. 2 pl., 2 fig. 1922.—An amoeba, for which the name *Phytamoeba sacchari* is proposed, is reported to be present in the galls of the Fiji disease of sugar cane (*Saccharum officinarum* L.). The organism is described as a small, intracellular, parasitic amoeba, capable of living in a free state in cane-juice cultures. The size is variable, seldom more than 12 μ in diameter. When the amoeba is intracellular, its pseudopodia are short, blunt, and lobose; when extracellular, in culture, the pseudopodia are lobose or pointed. The protoplasm contains granules rather uniformly distributed, with little or no differentiation of ectoplasm. Vacuoles are present, these being more or less contractile in the organism living under extracellular conditions. The nucleus is organized or distributed. When the gall becomes mature, each amoeba is transformed into a single cyst, which is a simple, rounded, smooth-walled structure. The cyst wall is firm but not brittle, and is composed of highly vacuolate material. When germinating, each cyst gradually absorbs its wall and becomes transformed into a motile amoeba. Reproduction takes place by simple fission and by gemination. In the developing galls, 1-6 amoebae may be present in each host cell; one or more are generally attached to the host nucleus. As the gall continues to develop, divisions of the amoebae accompany divisions of the host nuclei. When the gall approaches maturity, encystment of the amoebae occurs. There is no zoospore stage of the organism; also no coalescing of amoebae to form large plasmodia. Culture of the organism was extremely difficult, but fairly successful cultures were obtained by using juice from a diseased plant for making hanging-drop cultures. In the hanging drop were placed several very thin free-hand sections of galls. In such preparations the cysts germinated into active amoebae and the latter reproduced by fission. That the Fiji disease is caused by *Phytamoeba sacchari* cannot be considered demonstrated conclusively until pure cultures of the organism injected into healthy sugar-cane plants shall have produced the disease under controlled conditions. The evidence that this organism is the cause of the disease is as follows: From the time that the disease first appears, the organism in some stage or other is always present in the developing galls; it is abundant only in the galls, and it cannot be demonstrated in healthy plants.—*Sam F. Trelease.*

2645. Misra, C. S. *Oxycarenus laetus*; the dusky cotton bug. Rept. Proc. Fourth [Pusa] Entomol. Meeting p. 84-92. Calcutta, 1921.—This insect not only directly lowers the vitality of the seed and injures the lint but indirectly introduces a host of fungous and bacterial diseases which conjointly reduce the seed vitality to a minimum. Such damaged seeds are lighter in weight, somewhat discolored, and do not produce healthy and vigorous plants.—The adults and nymphs of this insect move freely about over the plant and are particularly active in the bolls, where they attack the seeds for their mucilaginous material. The seed coats in such cases show numerous fine perforations presumably made by the probosces of these bugs. Since this insect does not enter the unopened bolls its worst injuries follow attacks by the boll worm.—Details of life history are followed by an open meeting discussion.—*Frederick V. Rand.*

2646. Roubaud, E. [Flagellosis of cabbage.] Bull. Soc. Path. Exotique 15: 165. 1922.—At Vendée the writer observed this infection of bugs of cabbage 2 years ago and again last

year. Of *Pentatoma ornatum* collected in 1920 and 1921 more than 90 per cent of individuals in all stages were parasitized. Salivary infection was not seen. Infection was searched for in vain in diseased leaves and stems, even those most completely discolored by insect punctures. The author does not believe that one can really speak of flagellosis of cabbage, but rather that the weakened condition of the plants is due to the abundance of insect punctures. [See also Bot. Absts. 12, Entry 2632.]—*G. H. Godfrey.*

2647. ROUBAUD, [E.] [Flagellosis of Euphorbias.] Bull. Soc. Path. Exotique 15: 207. 1922.—The author states that he shares Franchini's opinion [see Bot. Absts. 12, Entry 2634] on the subject of the polyxenism of the flagellate *Leptomonas davidi* in Hemiptera and in Euphorbias. [See Bot. Absts. 12, Entry 2630.]—*G. H. Godfrey.*

2648. SEABRA, A. F. DE. Études sur les maladies et les parasites du cacaoyer et d'autres plantes cultivées à S. Thomé. VII. Quelques observations sur le "thrips" du cacaoyer. [Some observations on thrips of cacao.] 23 p., fig. 25-32. Sec. Tech. et Path. Vég. Companhia Agricola Ultramarina: Lisbon, 1919.—*Heliothrips rubrocinctus* Giard is one of the very common species of thrips, but has been known only a few years. In St. Thomas and Principe it has been found parasitizing both avocado and cacao. The author gives its geographical distribution, the plants parasitized, some biological observations including acclimatization, oviposition, and development of larval forms, life-history, classification and description of the species, prophylaxis and control treatments, description of parasitized material used for study, and bibliography.—*Frederick V. Rand.*

2649. SEABRA, A. F. DE. Études sur les maladies et les parasites du cacaoyer et d'autres plantes cultivées à S. Thomé. VIII. Sur une nouvelle espèce du genre *Mirotermes* appartenant à la faune de S. Thomé. [A new species of *Mirotermes* in St. Thomas.] 6 p., fig. 33-40. Sec. Tech. et Path. Vég. Companhia Agricola Ultramarina: Lisbon, 1919.—*Mirotermes obiectus* F. Silb. is an earth inhabiting species which builds its nest near the old trunks of trees and which seems to have a secondary agricultural importance, but is interesting from the point of view of morphology.—*Frederick V. Rand.*

2650. SEABRA, A. F. DE. Études sur les maladies et les parasites du cacaoyer et d'autres plantes cultivées à S. Thomé. IX. Les cochenilles du caféier. [The cochineals of coffee.] 8 p., fig. 41-49. Sec. Tech. et Path. Vég. Companhia Agricola Ultramarina: Lisbon, 1919.—The most important of these insects from the point of view of damage caused is *Pseudococcus citri* Risso which attacks not only the leaves and buds of several plants, but also the fruits, branches, large trunks, and roots. It is to the roots that greatest injury results. The waxy flakes forming the secretion which shelters the colonies of this species occur in abundance upon the small trunks and roots of young plants. Species of *Pseudococcus* and *Dactylopus* are very difficult to combat not only on account of this natural protection but also because of their habit of entering fissures in the bark, and of going into the ground to the roots and even to decaying vegetable matter remote from the roots.—Other species discussed are *Cero-plastes* sp., *Ischnaspis filiformis*, *Orthesia insignis* Douglas, *Lecanium viride* Green, *Pseudomoni-dia trilobitiformis* Green, *Aspidiotus palmarum* Morg. & Ckll., and *A. articulatus* Morg.—*Frederick V. Rand.*

2651. SEABRA, A. F. DE. Études sur les maladies et les parasites du cacaoyer et d'autres plantes cultivées à S. Thomé. XI. Les grandes espèces d'insectes ravageurs des vieux arbres à S. Thomé. [The large insects destructive to old trees in St. Thomas.] 8 p., 3 pl. Sec. Tech. et Path. Vég. Companhia Agricola Ultramarina: Lisbon, 1921.—The author discusses not only the direct insect injuries but also the relation of these wounds to the entry of cryptogamic parasites. Two families of the order Coleoptera are described.—*Frederick V. Rand.*

2652. SEABRA, A. F. DE. Études sur les maladies et les parasites du cacaoyer et d'autres plantes cultivées à S. Thomé. XIV. Le "*Toxoptera coffeae* Nietner," à S. Thomé (*Toxoptera coffeae* Thomensis s. sp. n.) [*Toxoptera coffeae* in St. Thomas.] p. 15-18, 9 fig. Sec. Tech. et Path. Vég. Companhia Agricola Ultramarina: Lisbon, 1921.—The extremities of the branches, particularly on young plants, are attacked. This insect causes atrophy of the leaves, and the young branches are also severely injured from its depredations.—*Frederick V. Rand.*

2653. SEABRA, A. F. DE. Études sur les maladies et les parasites du cacaoyer et d'autres plantes cultivées à S. Thomé. XX. Note préliminaire sur la maladie vermiculaire du caféier à S. Thomé. [Preliminary note on nematode disease of coffee.] 6 p. Sec. Tech. et Path. Vég. Companhia Agricola Ultramarina: Lisbon, 1920.—The preconceived idea that the death of coffee plants in this island is due to cryptogamic parasites of the roots has retarded investigations. It is true that roots of the coffee plant as well as those of cacao, avocado, and other trees will, when left for several days in the field, show a whitish mycelium usually resembling the *Rosellinia* which attacks trees and particularly the vine in Europe. However, this mycelium may belong to other fungi, especially to saprophytic forms such as the *Agaricaceae*, etc. It is necessary to determine the species before pronouncing on its possible importance to pathology.—The disease now under discussion is of another order and is due to the nematode *Heterodera* sp. A description of the symptoms, agricultural importance of the disease in St. Thomas, and suggestions for treatment are given.—*Frederick V. Rand.*

2654. SEABRA, A. F. DE. Études sur les maladies et les parasites du cacaoyer et d'autres plantes cultivées à S. Thomé. XXII. Le *Cosmopolites sordidus* Germ. à S. Thomé. [*Cosmopolites sordidus* in St. Thomas.] 7 p., 3 fig. Sec. Tech. et Path. Vég. Companhia Agricola Ultramarina: Lisbon, 1920.—The larvae of this insect live at the base of the trunk and in the roots of the banana tree producing numerous galleries which permit water to enter the interior of the plant. Decay produced by the development of parasitic or semi-parasitic cryptogams soon follows.—Several other insects and myriopods are mentioned.—*Frederick V. Rand.*

2655. SEABRA, A. F. DE. Études sur les maladies et les parasites du cacaoyer et d'autres plantes cultivées à S. Thomé. XXX. Encore le thrips du cacaoyer (*Heliothrips rubrocinctus* Giard.) à S. Thomé. [*Heliothrips rubrocinctus* on cacao in St. Thomas.] 5 p. Sec. Tech. et Path. Vég. Companhia Agricola Ultramarina: Lisbon, 1920.—This species is reported on *Claoxylon Molleri* Pax., *Copaifer mapane* Kirk, *Maniot utilissima* Pahlz., *Pseudospondias microcarpa* Engler, *Psidium pomiferum* L., and *Urophyllum insular* Hiern. The symptoms of attack are described for each species of plant.—The use of tobacco as a trap crop is discussed, and it is stated that tobacco not only attracts the thrips but also poisons them.—Thrips are regarded as a potentially formidable enemy of the St. Thomas plantations unless serious attention is paid to a reduction of their natural multiplication.—*Frederick V. Rand.*

INFECTIOUS CHLOROSES (MOZAIC AND PEACH YELLOWS GROUPS, ETC.)

2656. ANONYMOUS. Transmission of sugar-cane mosaic by aphids. West India Committee Circ. 37. 521. 1922.—In a Porto Rico cane field 2 large insect-proof cages were erected, each containing 48 plants of a particularly susceptible variety; one half the plants in each cage were diseased, the other half healthy. Aphids were introduced into cage A, while cage B was kept free from weeds and insects. In 3 months 15 of the 24 healthy cane plants in cage A had contracted the disease while in cage B, the healthy plants showed no sign of infection.—*H. N. Vinall.*

2657. HARREVELD, PH. VAN. Gelestrepenziekte. [Yellow-stripe disease (mosaic).] Arch. Suikerindust. Nederland.-Indië 30: 362-364. 1922.—This article is a discussion and refutation of some of F. Ledeboer's remarks [see Bot. Absts. 12, Entry 2661] in regard to van Harreveld's note on stripe disease [Arch. Suikerindust. Nederland.-Indië 30: 261-262. 1922]. He repeats that the methods used for control do not have to be changed to any extent. Control

measures were selection of healthy plants in young bibit-gardens and eradication of stripe-diseased plants. Naturally bibit-gardens are kept clear from grasses and weeds from a cultural point of view. Corn and grass are too generally present to make the killing or the exclusion of corn aphids possible.—Strains of cane D. I. 52 and the Chunnee crosses, P. O. J. Nos. 36, 826, 979, 1499, 1507, 1547, and 2379, sometimes become suddenly more than 50 per cent diseased.—In general old methods of control have more value since the discovery that insects can transmit the disease from plant to plant.—*Peter J. Klaphaak.*

2658. JOHNSON, JAMES. The relation of air temperature to the mosaic disease of potatoes and other plants. *Phytopathology* 12: 438-440. *Fig. 1.* 1922.—The optimum temperature for the development of potato (*Solanum tuberosum*) mosaic lies between 14 and 18°C. Above 20°C. the mosaic symptoms gradually disappear from diseased plants. At a temperature of 24-25°C. the symptoms disappear entirely in 1-2 weeks.—*B. B. Higgins.*

2659. K[UYPER?], J. Overbrenging van Gelestrepenziekte door insecten. [Transmission of yellow-stripe disease (mosaic) by insects.] *Arch. Suikerindust. Nederland.-Indië* 30: 357-358. 1922.—This article contains a discussion of Kunkel's paper in Hawaiian Planters Rec. 26: 1922 in which Kunkel mentioned that in confirmation of Brandes' work *Aphis adusta* (*maidis*) could transmit the disease, while *Aphis sacchari* Zehntn. could not. The former, however, was seldom found on cane, but quite often on grasses present in the cane fields. Some of the grasses mentioned by Kunkel, a few of which are susceptible to the mosaic disease, occur in Java, e.g., *Eleusine indica*, *Panicum colomun*, and *P. sanguinale*. Van der Goot found *Aphis maidis* also on *Polytrias diversiflora*.—*Peter J. Klaphaak.*

2660. LEDEBOER, F. Gelestrepenziekte. [Yellow-stripe disease (mosaic).] *Arch. Suikerindust. Nederland.-Indië* 30: 359-362. 1922.—After discussing van Harreveld's note on Gelestrepenziekte en Bladluizen [*Arch. Suikerindust. Nederland.-Indië* 30: 261. 1922] the author gives the results of investigations during 1921-1922. It was found that *Aphis sacchari* Zehntner could not transmit the disease, as was at first surmised, but that *A. adusta* Zehntner was a very active carrier, thus confirming Brandes' results. *A. adusta* was found more often than would be expected. Evidence of a real attack is very seldom found, but during the rainy season the insects are found in abundance on several grasses. From these grasses winged individuals go to the cane. *Panicum colonum* L. and *Paspalum sanguinale* Lam. are the most frequent host plants for *Aphis adusta*. Grasses in the neighborhood of stripe-diseased cane are often stripe diseased also, and serve thus not only as hosts for the insects, but also as new sources of infection when stripe-diseased cane has been eradicated.—Control measures are the eradication of stripe-diseased plants, careful weeding in and around the plantation, burying or burning the weeds, and growing of infected cane only in the lowlands where it is more easily controlled. [See also Bot. Absts. 12, Entry 2658].—*Peter J. Klaphaak.*

2661. MCCALLAN, E. A. Report of seed potato inspection. *Agric. Bull. Bermuda Dept. Agric.* 1922: 4-7. September, 1922.—The report gives comparative counts of leaf-roll and mosaic in the same stock in Bermuda and Nova Scotia for 1921-1922.—*H. H. Whetzel.*

2662. MURPHY, PAUL A. Leaf-roll and mosaic, two important diseases of the potato. *Jour. Dept. Agric. Ireland* 22: 281-284. *Fig. 1-2.* 1922.—The usual symptoms and behavior are described. Capsid bugs and jassids have been proved to transmit leaf-roll in Ireland, and there they apparently are more important in this respect than aphids. Recommended control measures are field inspection for the source of seed, early removal of diseased hills, isolated seed-plots, and avoidance of soil containing diseased tubers and of conditions favoring infestation by transmitting insects.—*Donald Folsom.*

2663. WHETZEL, H. H. The seed potato situation. *Agric. Bull. Bermuda Dept. Agric.* 1922: 2-4. September, 1922.—The Bermuda seed potato problem is presented, with special reference to leaf-roll and mosaic.—*H. H. Whetzel.*

2664. WILCOX, R. B. **Eastern blue-stem of the black raspberry.** U. S. Dept. Agric. Dept. Circ. 227. 12 p., 1 pl. 1922.—This trouble is apparently not due to a "running out" of varieties; there is no indication of a parasite of any kind, and the probabilities are that the disease is of mosaic type. There is a gradual stunting and reduction of vigor in the affected plant. The shoots become shortened, the upper leaves become curled in a peculiar fashion, and the fruit is inclined to crumble. A uniform mottling of the leaves usually accompanies the change in form. A constant symptom is the discoloration of shoots; this discoloration, an indulin blue (Ridgeway), occurs at or near the surface of the ground and upward for 2 feet or more. The blue coloration is found in the chlorophyll area of the stem. This disease differs from blue-stem in the West [U. S. A.], which shows a wilting of the leaves and a darkening of the canes. Mosaic and leaf-curl are different; in the latter the tissue arches upward in a fashion not found in eastern blue-stem. The variety Hoosier seems to be most susceptible while the Kansas seems to possess the greatest resistance. Other varieties are also susceptible. Suggestions for control are given.—*L. R. Hesler.*

PARASITIC PHANEROGAMS

2665. GRINȚESCU, IOAN. **Note sur deux Orobanches parasites des plantes cultivées et sur leur origine en Roumanie.** [Note on two Orobanches parasitic on crop-plants and their source in Rumania.] Bul. Soc. Științe Cluj 1: 136-140. 1921.—This paper deals with 2 Orobanches which cause serious injury especially in Dobrudja, namely *Phelipaea ramosa* C. A. Mey. and *Orobanche cumana* Wallr. The first parasitizes especially the roots of *Cannabis sativa*, *Nicotiana rustica*, *Solanum tuberosum*, and *S. Lycopersicum*. In the absence of cultivated plants it grows on many weeds, the most important of which are given. The typical form occurs in Rumania. It originated in the steppes of Asiatic Russia and has spread apparently with the cultivation of *Cannabis* as far as Portugal.—More interesting still is *Orobanche cumana*, which formerly was little known in Rumania. It lives especially on the roots of *Nicotiana rustica*, *Artemisia austriaca*, *Xanthium strumarium*, and *Helianthus annuus*. It has spread from its native home in the region of the Caspian Sea over Bessarabia, Dobrudja, and the plateau of Moldavia. Apparently this species is gradually spreading, following the cultivation of *Helianthus annuus*.—*M. Tiesenhausen.*

2666. LONG, W. H. **Mistletoe and smelter smoke.** Phytopathology 12: 535-536. 1922.—In an area of the woodland type which had been exposed to smoke from a copper smelter there were many junipers (*Juniperus monosperma*). Close to the smelter these trees were dead, while further away they showed varying degrees of injury. Some 50 of the living junipers were infected by mistletoe (*Phorodendron juniperinum*) all of which had evidently been dead for more than a year. The author is making a more intensive study in the hope that some practical method for control of mistletoe may be worked out.—The smoke was said to contain compounds of sulphur and arsenic.—*Lillian C. Cash.*

2667. McWHORTER, FRANK P. **Concerning the sugar cane root parasite, Aeginetia indica.** Philippine Agric. 11: 89-90. 1 pl. 1922.—S. KUSANO's work [Further studies on *Aeginetia indica*. Bull. Coll. Agric. Tokyo Imperial Univ. 8: 59-79. 1908] on this parasite is reviewed, and control measures are suggested, based on earlier work and on the author's observations in the Philippines. *Aeginetia indica* L. is found on many wild, and on a number of cultivated, grasses including maize (*Zea Mays* L.), rice (*Oryza sativa* L.), and sugar cane (*Saccharum officinarum* L.).—*Sam F. Trelease.*

NON-PARASITIC DISEASES

2668. BENNETT, J. P., and E. T. BARTHOLOMEW. **Respiration of potatoes in relation to the occurrence of blackheart in storage.** [Abstract.] Phytopathology 12: 443. 1922.

2669. HERBERT, D. A. **Bitter pit in apples: the crushed cell theory.** Phytopathology 12: 489-491. 1922.—It is here suggested, and evidence supporting the theory is discussed, that

the dead cells of the pit area are those in which starch transformation has been backward and that they have been crushed by the higher osmotic pressure of the surrounding cells.—*B. B. Higgins.*

2670. LUTMAN, B. F. Relation of structure of potato leaves to tip burn. *Potato Mag.* 51: 6, 22-23. 6 fig. 1922.

2671. REDDY, C. S., and W. E. BRENTZEL. Investigations of heat canker of flax. U. S. Dept. Agric. Bull. 1120. 18 p., 5 pl. 1922.—The heat-canker type of flax injury is of non-parasitic origin and occurs somewhat uniformly each year in the northern Great Plains area, causing marked losses. The cortex of the stem is killed at the surface of the ground and sooner or later the plants topple over. While the young cankered plants die at once, those a little older may remain alive for days or weeks, as long as the vascular systems function. Stems usually enlarge just above the injury and sometimes also just below it, resulting in a girdling of the plants at the soil line. Flax plants canker only during or immediately following very hot days and are only slightly susceptible after they are 4 inches or more high. They are somewhat protected from canker by the use of cereals as nurse crops or even by weeds, and also by shading, or by a shallow surface mulch over a firm seed bed. Killing the cortex of young plants by artificial heat produced typical heat canker. The evidence indicates that a combination of succulence and high temperature of the soil surface favors canker formaton, especially in soil compacted into a crust by rains. Thicker seeding, early sowing, and drilling the rows north and south instead of east and west are suggested as helpful in lessening the severity of canker injury.—*J. T. Buchholz.*

GENERAL AND MISCELLANEOUS PATHOLOGICAL LITERATURE

2672. BEZSSONOFF, N. La sterilisation partielle du sol et ses applications en phytopathologie. [The partial sterilization of soils, and its phytopathological applications.] *Bull. Soc. Path. Vég. France* 9: 169-188. 1922.—This is a review of the various papers by Russell, Henderson, Hutchinson and others. Although good results are acknowledged from the use of chloropicrine treatments of nematode-infested soils the author records the best results from the use of a mixture of calcium sulphide with naphthalene to which fertilizing materials (phosphate and potash) are added. From experiments by Rivière and Pichard, Lowett, and Paillet the use of sodium arsenite, and possibly also of calcium arsenite, at the rate of 40 gm. per square m. is suggested. Sodium cyanide also should prove an efficient and cheap disinfectant. In the experiments of Truffaut cymene (paramethyl-isopropyl-benzene) at the rate of 100 gm. per square m. greatly increased the yields of treated soils.—*J. Dufrénoy.*

2673. CASTELLA, F. DE. Bordeaux mixture. Should it be acid or alkaline? *Jour. Dept. Agric. Victoria* 18: 749-754. 1920.—The author gives a brief résumé of the history of Bordeaux mixture and its chemical nature followed by a review of recent investigations published by Jean Chauzit in *La Revue de Viticulture* for May and June. The results show that Bordeaux is effective regardless of its chemical composition, but that alkaline mixtures retain their effectiveness for a longer time, especially in rainy weather.—*Wm. E. Lawrence.*

2674. DAVIS, W. H. Staining germinating spores. *Phytopathology* 12: 492-494. 1922.—Detailed directions for staining germinating spores of fungi are given.—*B. B. Higgins.*

2675. DUFRÉNOY, J. Engrais et poisons des plantes. Desinfection des sols. [Substances nutrient or toxic to plants. Soil disinfection.] *Bull. Soc. Path. Vég. France* 9: 223-224. 1922.—Various species of phanerogams are unequally tolerant of metallic ions and react differently to the presence of metallic ores in the ground, or to the addition of disinfectants to the soil.—*J. Dufrénoy.*

2676. FROMME, F. D. Experiments in spraying and dusting tomatoes. *Virginia Agric. Exp. Sta. Bull.* 230. 15 p., 4 fig. 1922.—Satisfactory control of leaf-blight (*Septoria Lyc-*

persici) was obtained in 7 separate tests in Virginia with soap Bordeaux (4 pounds copper sulphate, 2 of resin fish-oil soap, 3 of quick lime, 50 gallons water). The increase in bushels per acre on plats sprayed with this material ranged from 34 to 125 and the percentage increase from 37 to 107. The number of applications ranged from 2 to 5. Greater yields were obtained with a 3 by 4 spacing of plants than with a 4 by 5 spacing. Soap Bordeaux also gave excellent control of bacterial soft rot (*Bacillus* sp.) the percentage of control based on the check plat being 68 while that of standard Bordeaux was 36. Seven applications of copper-lime dust gave satisfactory control of late-blight (*Phytophthora infestans*) the increase in ripe fruit being 72.7 per cent and the decrease in unsound fruit 69 per cent. The percentage of unsound fruits in the dusted plats ranged from 14 to 27.3 (average 18.3) and that of the check plats from 45.9 to 75.2 (average 55.4). The practicability of spraying or dusting must be determined locally and varies according to market value of the product, cost of material and application, and severity of disease.—*F. D. Fromme*.

2677. K[UYPER?], J. Colloidale Zwavel als middel tegen plantenziekten en witte luis. [Colloidal sulphur as control measure against plant diseases and woolly aphids.] Arch. Suiker-indust. Nederland.- Indië 30: 671. 1922.—The author discusses a preparation, brought into the trade by the factory "De Haën" in Hanover (Germany), which consists of sulphur that can be made into a colloidal solution with water for spraying. Some experiments were made with Dutch material against white woolly aphids, an extreme attack of which occurred during the harvest of 1921-1922. A solution of 1-2 per cent, gave good results and killed the lice without burning the leaves.—*Peter J. Klaphaak*.

2678. MACMILLAN, H. G. Influence of the meteorological factors on potato disease and production in Colorado. [Abstract.] Phytopathology 12: 445. 1922.

2679. MANGIN, L. La lutte contre les ennemis des végétaux. (1). [Fighting plant pests.] Bull. Soc. Path. Vég. France 9: 213-220. 1922.—The importance of biological researches on both host and parasite, in order to know how and when to apply control treatments, is emphasized by reference to the researches of Cazeaux, Cazalet and Capus, and Ravaz on mildew, and to the work of American entomologists on the boll-weevil.—The use of entomophagous insects is advocated from the results obtained by Marchal with *Novius cardinalis*, by Berlese with *Prospatella Berlesi*, and by Howard with *Calosoma sycophante*.—The ideal of modern plant pathologists is prophesied to lie in the selection of disease-resistant varieties such as those obtained by Planchon, Millardet, and Ravaz and Viala for mildew-resistant *Vitis*; and by American geneticists for the rust-resistant wheats and *Fusarium*-resistant plants.—*J. Dufrénoy*.

2681. MELCHERS, L. E. Plant diseases heretofore unreported in Kansas. Trans. Kansas Acad. Sci. 30: 196-197. 1919/21 [1922].—A list of plant diseases was reported in 1914, including 8 diseases or disease-host relations new to science: *Heterodera radicolica* on Canada thistle, Madagascar periwinkle, marguerite, cockscorn, phlox, and parsley; black chaff and stem disease of wheat (bacterial); *Pleosphaerulina briosiana* Pol. on alfalfa. In 1915, 9 were reported; in 1916 and 1917, 7 were reported, including the following 4 new to science: *Alternaria* on pepper, *Botrytis* on geranium, bacterial disease of lettuce in the greenhouse, and bud blight of sorghum caused by a fungus.—*F. C. Gates*.

2682. MELCHERS, L. E. Plant-disease survey report for Kansas, 1918. Trans. Kansas Acad. Sci. 30: 197-201. 1919/21 [1922].—This is an annotated list of diseases, including cereal diseases (barley, oats, rye, winter wheat, alfalfa, corn, and sorghum), vegetable diseases (bean, cucumber, beets, cabbage, celery, eggplant, potato, sweet potato), and fruit diseases (apple, blackberry, plum, raspberry, and watermelon). In general, the plant disease situa-

tion was ordinary during 1918 except for the occurrence of the new apple canker disease due to *Leptosphaeria coniothyrium*.—F. C. Gates.

2683. MÜLLER, KARL. *Rebschädlinge und ihre neuzeitliche Bekämpfung*. [Grape diseases and the latest methods for their control.] 2nd ed., enlarged, 213 p., 70 fig., 1 map. G. Braun: Karlsruhe, 1922.—The problems of the vine grower in Germany are treated under the following headings: General considerations relative to grape diseases; the Peronospora disease and its treatment; the application of sprays; the grape mildew; various diseases due to winter injury, soil conditions, and fungi; injury due to *Conchylis ambiguella*; other diseases caused by animals; the grape *Phylloxera*, its spread and control; the cultivation of vines resistant to *Phylloxera*; and the development of new varieties.—Lillian C. Cash.

2684. NIXON, E. L. *Profitable potato spraying*. Potato Mag. 4¹⁰: 5-6, 13, 19. 5 fig. 1922.—In 4 years, 1918-1921, 876 demonstrations in 57 counties of Pennsylvania showed an average increase of 56.7 bushels per acre, an increase of 36.7 per cent.—Donald Folsom.

2685. ORTON, W. A., and F. C. MEIER. *Diseases of watermelons*. U. S. Dept. Agric. Farmers Bull. 1277. 31 p., 21 fig. 1922.

2686. PATOULLARD, N. *Études sur les maladies et les parasites du cacaoyer et d'autres plantes cultivées à S. Thomé*. XVII. Quelques parasites du cacaoyer à S. Thomé. [Some parasites of cacao-tree in St. Thomas.] 7 p., 2 fig. Sec. Tech. et Path. Vég. Companhia Agricola Ultramarina: Lisbon, 1921.—Two important diseases of the cacao-tree, under the vernacular names "gafa" and "mela," occur in St. Thomas. The former attacks the branches, the latter the fruits.—Specimens of the "gafa" disease examined bore an alga, *Cephaleuros virescens* Kunze, and the following fungi: *Nectria albiseda* and its conidial form, *Fusarium Theobromae* App. & Strunk, *Phoma Theobromae*, and *Anthromycopsis filiformis*. The last is probably saprophytic. Diseased fruits affected with "mela" bore *Colletotrichum Theobromae* App. & Strunk, *Stilbum Seabrae*, and *Nectria ochroleuca* Schw. Each fungus is briefly described.—Frederick V. Rand.

2687. PETHYBRIDGE, G. H., H. A. LAFFERTY, and J. G. RHYNEHART. *Investigations on flax diseases*. (Third report.) Jour. Dept. Agric. Ireland 22: 103-120. Fig. 1-11. 1922.—Seedling blight (*Colletotrichum linicolum* Pethybr. & Laff.) was suppressed in 1921 by drought. Browning and stem-break, diseases due to *Polyspora Lini* Laff., were less prevalent than usual. The fungus was disseminated from lower to higher leaves by flax flea-beetles, and was not controlled by spraying with 2 per cent Bordeaux mixture or by seed treatments with copper sulphate, lime, and formaldehyde. The diseases rust and firing are due to *Melampsora Lini*. The teleutospores remain infective after 21 months in a dry place; a biologic race on *Linum catharticum* does not infect cultivated flax. *Thielavia basicola* (B. and Br.) Zopf., proved by inoculations to be the pathogen of root-rot, was also found in the weeds *Senecio vulgaris* and *Chenopodium album*. Flax-droop (no pathogen found) was the result of fiber degeneration in plants of tall-growing pure lines. The pathogen of the Sclerotium disease (*Sclerotinia sclerotiorum* Mass. = *Sclerotinia Libertiana* Fuck.) was cross-inoculated successfully to potato. Alleged frost injury is probably mostly seedling-blight injury. Insect pests are discussed.—Donald Folsom.

2688. RAMSAY, A. A. *The preparation of colloidal sulphur*. Agric. Gaz. New South Wales 33: 819-823. 1922.—It is practicable to prepare colloidal sulphur on the farm from home-made lime-sulphur mixtures at $\frac{1}{4}$ - $\frac{1}{2}$ the cost of proprietary colloidal sulphur preparations. Results of experiments and analyses are given together with methods of preparation and estimates of cost. Each gallon of lime-sulphur mixture was found to yield about 1.25 pounds of colloidal sulphur.—L. R. Waldron.

2689. [SCHOENE, W. J.] General rules governing the certification of sweet potatoes. Quart. Bull. Virginia State Crop Pest Commission 4: 4 p. 1923.—The rules apply in Virginia and include methods of bedding for certification.—F. D. Fromme.

2690. [SCHOENE, W. J.] Progress report cedar rust eradication. Quart. Bull. Virginia State Crop Pest Commission 4: 4 p. 1922.—Recent progress of cedar eradication as a measure of protection for apple orchards in certain counties in Virginia is discussed. During the period from December 15, 1921, to July 1, 1922, there were 127 petitions filed with the State Entomologist involving an area of 12,721 acres.—Data are also given on crown gall inspection work.—F. D. Fromme.

2691. SEABRA, AMANDO DE. Estudos sobre as doenças e parasitas do cacauero e de outras plantas cultivadas em S. Tomé. XVIII. A moléstia nova dos cacaueros na Ilha de S. Tomé. [The new disease of cacao trees on the Island of St. Thomas.] 43 p. Sec. Téc. e Patol. Veg. Companhia Agricola Ultramarina: Lisbon, 1919.—The disease attacks the pods of cacao trees and is caused by *Heliothrips rubrocinctus* Giard., and *Lasiodiplodia Theobromae*.—The insect multiplies rapidly during the dry season and causes first a rusting and change of color of the capsules which resembles the scab of Brazil and Trinidad. This is followed by leaf injury and slow defoliation. During the following rainy season the fungus enters through neglected wounds or insect injuries and causes a drying and dying of ends of branches of adult trees and entirely kills the young trees under 5 years of age.—Fungous threads come to the surface on all infected parts through pores and cracks in the bark. The interior of the bark of infected areas is covered with a fungous mycelium. *Nectria* also does considerable damage and other fungous fructifications accompany those of *Lasiodiplodia*. A number of synonyms for the fungus *Lasiodiplodia Theobromae* are given.—Tobacco solution kills all insects with which it comes in contact but does not give protection against surviving insects or new colonies. Bordeaux controls the fungus. The author recommends Russel's formula for tobacco infusion and a combined treatment with tobacco and Bordeaux. The growing of tobacco as a trap crop is recommended. Infected capsules, branches, and trees should be burned.—The author considers this the most serious disease attacking cacao trees. In 1919 the total loss on St. Thomas was about 10 per cent of the annual crop.—Charlotte Elliott.

2692. SEABRA, AMANDO DE. Estudos sobre as doenças e parasitas do cacauero e de outras plantas cultivadas em S. Tomé. XIX. A seca dos ramos dos cacaueros. [The drying of branches of cacao trees.] 40 p. Sec. Téc. e Patol. Veg. Companhia Agricola Ultramarina: Lisbon, 1919.—Drying and subsequent defoliation may be due to drought or to strong winds. A. Drying due to plant parasites. "Gafa" or drying of the ends of branches is an annual disease becoming serious only during periods of great humidity or high temperature. It attacks trees of all ages especially those overcrowded. The initial infection is due to *Lasiodiplodia Theobromae*, which can attack uninjured branches. *Nectria* and *Corticium* are commonly associated with it and also *Macrophoma*, *Fusarium*, *Melanoma Henriquesianum*, and an alga, *Cephaleurus virescens*. Disinfection of wounds, pruning and burning of infected branches, and application of Bordeaux control this disease. (2) Sudden death. This is not a nutritional disease but is due to a severe attack of *Lasiodiplodia Theobromae*. The leaves begin to turn yellow in a day, the yellowing becomes more intense and in a few days the whole tree is dry and sapless, the leaves and fruits adhering to the branches for some time. The bark becomes suberized and thickened and through interference with its normal functioning death of the tree results. Plants 4-8 years old and those less resistant to unfavorable climatic conditions are more often attacked. Curative treatments are ineffective. Careful cultural methods greatly lessen infection. (3) Rotting of the base of trunk and roots. *Lasiodiplodia Theobromae* causes the initial infection. *Corticium* and *Nectria* are almost constantly associated with the disease, and *Colmariaecae*, *Pleonectria*, and higher forms are also found. It attacks plants of all ages, and unlike "Gafa," which disappears with change of climatic conditions, this decay of trunk and roots continually increases until the tree is killed. Lesions first appear as dark areas on the bark from 1-2 feet above the crown down to the exposed

roots. The bark is thickened and as the disease progresses becomes loosened, disclosing a thick layer of white mycelium. Later the bark splits longitudinally and the wood radially, the mycelial layer covering the cracks. The base of the trunk and roots appear much enlarged and saturated with moisture. If treated in the early stages this disease can be entirely overcome. Diseased bark and wood should be cut out and exposed surfaces disinfected with a concentrated solution of sulphate of iron. New soil should be placed around the roots.—The author thinks these 3 diseases are only more or less complicated stages due to the same parasite.—B. Drying due to insects. (1) *Cochonilla* (*Aspidiotos trilobitiformis* Green or *Pseudaonidia trilobitiformis* Green) attacks the leaves causing yellowing and defoliation. Various insecticides were tried but none proved as effective as the fungus *Microcera cocophila* in destroying the insects. (2) *Neotermes Gestri* enters the branches of old trees through wounds, destroys the subcortical layer, working from upper to lower branches by means of galleries until the whole trunk is destroyed. Darkening of branches, exudate, and accumulations of woody detritus mark the locations of nests, which should be cut off and burned. (3) *Heliothrips rubrocinctus* attacks leaves and capsules. The greatest injury, however, is indirect, the defoliation and weakening of the trees facilitating the entrance of *Lasiodiplodia Theobromae*. (4) Borers of the genus *Zeuzera* attack branches of plants not receiving proper care.—Charlotte Elliott.

2693. SEABRA, A. F. DE. Estudos sôbre as doenças e parasitas do cacauero e de outras plantas cultivadas em S. Tomé. XXIX. Notas sôbre as principais formas de animais e plantas interessando a agricultura de S. Tomé e particularmente a cultura do cacau.) [Notes on the principal animals and plants of interest to the agriculture of St. Thomas.] 13 p. Sec. Téc. e Patol. Veg. Companhia Agricola Ultramarina: Lisbon, 1919.—This is a list of fungi, insects, and higher animals and the plants to which they are beneficial or injurious on the Island of St. Thomas.—Charlotte Elliott.

2694. SMITH, LOREN B., and H. H. ZIMMERLEY. Relation of pressure to effectiveness in spraying tomatoes. Virginia Truck Exp. Sta. Bull. 33/34. 163-190, fig. 26-34. 1920.—It is estimated that early-tomato growers in the region of Norfolk, Virginia, lose annually 20-25 per cent of the crop through the tomato fruit worm (*Chloridea obsoleta* Hbn.) and 25-30 per cent additional from leaf mold (caused by *Cladosporium fulvum* Cke.) and leaf spot (caused by *Septoria Lycopersici* Speg.). The following results were obtained by the Bordeaux-lead arsenate spray (4-6-50 + 2 pounds powdered lead arsenate) when applied at the pressure indicated. Seven applications of spray were made in 1919 and 5 in 1920.—The plots sprayed at 200 pounds pressure gave the largest average yield of marketable fruit, exceeding per acre the unsprayed plots by 4,603 pounds in 1919 and 6,202 pounds in 1920. Those sprayed at 140 pounds pressure outyielded the unsprayed plots by 3,323 pounds marketable fruit per acre in 1919 and 5,020 pounds in 1920. On the same basis the plots sprayed at 75 pounds pressure outyielded the unsprayed plots by 2,582 and 3,884 pounds in 1919 and 1920 respectively. In 1919 the plots sprayed at 200, 140, and 75 pounds pressure had respectively 16.25, 16.51, and 16.81 per cent of the fruit injured by fruit worms; the injury on the unsprayed plots was 25.23 per cent. In 1920 the 200, 140, and 75 pound application-pressure plots had respectively 11.70, 14.24, and 15.12 per cent of the fruit injured by worms; the unsprayed controls had 21.39 per cent. In 1919, after deducting the increase in yield due to worm control, the plots sprayed at 200, 140, and 75 pounds pressure gave average increases in yield due to fungus control of 3,025, 2,052, and 1,341 pounds of marketable fruit per acre respectively; in 1920 the corresponding increases were 4,177, 3,608, and 2,695 pounds. Copper soap spray ($\frac{1}{2}$ pound copper sulphate, 3 pounds resin fish oil soap, water to make 50 gallons) used during the same years did not give as good results as did Bordeaux.—H. A. Jones.

2695. SNAPP, O. I., W. F. TURNER, and J. W. ROBERTS. Controlling the curculio, brown-rot and scab in the peach belt of Georgia. U. S. Dept. Agric. Dept. Circ. 216. 30 p., 17 fig. 1922.—This is a discussion of the growth of the peach industry in Georgia since 1890, losses from curculio and brown-rot (*Sclerotinia cinerea* (Bon.) Schr.), relation of curculio injury to

brown-rot, orchard sanitation for curculio control, disking as a control measure, and spraying and dusting. Directions for spraying and dusting and a schedule for each are given.—*L. R. Hesler*.

2696. SOURSAC, LOUIS. Étude de quelques maladies de la laitue et des moyens de les prévenir ou de les combattre. [Some diseases of lettuce and their control.] Bull. Soc. Path. Vég. France 9: 207–213. 1922. [For an almost identical account of the *Sclerotinia* disease see also SOURSAC, LOUIS. Rev. Bot. Appl. et Agric. Coloniale 2: 562–567. 1922.]—*Sclerotinia libertiana* causes much damage in the sandy soils of southern France during moist summers. The different varieties of lettuce are not equally susceptible, the “Romaine” being practically resistant. All drooping lettuce plants should be removed. Crop rotation is also suggested.—Two physiological diseases are very briefly described: “Cabuchage” and stem-fusion.—*J. Dufrénoy*.

2701. ANONYMOUS. [Rev. of: HUMPHREY, J. Drugs in commerce: their source, preparation for the market, and description. (Pittman's Common Commodities and Industries.) *x* + 116 p., 12 pl. Sir Isaac Pitman and Sons: London, no date.] Nature 110: 7. 1922.

2702. FOY, WM. H. Tables for the microscopic identification of inorganic salts. U. S. Dept. Agric. Bull. 1108. 22 p. 1922.—The author describes the petrographic methods applied to the identification of inorganic salts. This method has great advantage in the identification of salts found in soils, fertilizers, scouring soaps, in dye manufacture, ground glass and sand in foodstuffs, incrustations and efflorescences on buildings, gas pipes, chemical precipitates, etc., and especially in inspection of drugs and similar products. Extensive tables are given showing optical properties of many inorganic salt crystals.—*J. T. Buchholz*.

2703. HOUSEMAN, PERCY A. Analysis of licorice root and licorice extract. Jour. Assoc. Official Agric. Chem. 6: 191–196. 1922.—Analytical methods are given for licorice root and extracts, with further remarks on various constituents extracted by solvents and not determined quantitatively.—*F. M. Schertz*.

2704. KINSLEY, A. T. Cocklebur poisoning in swine. Vet. Med. 17: 282–283. 1922.—A brief description is given of *Xanthium*. The burs injure the wool of sheep, and the poison-

ous young plants cause the death of swine. A short description is given of the symptoms exhibited by poisoned animals and of the lesions produced.—*C. D. Marsh.*

2705. PAMMEL, L. H. Blue vervain suspected poisonous to hogs. *Vet. Med.* 17: 385. 1922.—It is stated that blue vervain, *Verbena hastata*, is not eaten by live stock, and is not the cause of poisoning.—*C. D. Marsh.*

2706. PAMMEL, L. H. Fool's parsley. *Vet. Med.* 17: 649. 1922.—*Aethusa cynapium*, a European plant, is said to be poisonous to stock in New Mexico. Results of experiments on animals are quoted from Millsbaugh.—*C. D. Marsh.*

2707. PAMMEL, L. H. Hedge mustard. *Vet. Med.* 17: 385. 1922.—Reply to an inquiry concerning the cause of poisoning of a cow, the author states that he does not consider *Sisymbrium officinale* poisonous.—*C. D. Marsh.*

2708. PAMMEL, L. H. Is the bracken fern poisonous? *Vet. Med.* 17: 385. 1922.—Answering a correspondent, the work of Hadwen and Bruce is quoted as establishing the poisonous character of the common brake [*Pteris aquilina*].—*C. D. Marsh.*

2709. PAMMEL, L. H. Parsnip or buckeye poisoning. *Vet. Med.* 17: 387. 1922.—Explaining a case of a poisoned cow, wild parsnip, *Pastinaca sativa*, is considered not poisonous. The Ohio buckeye is poisonous under certain conditions, especially when young.—*C. D. Marsh.*

2710. PAMMEL, L. H. Sneezeweed. *Vet. Med.* 17: 387. 1922.—Sneezeweed is poisonous to cattle, sheep, and horses, the poisonous principle being principally in the flowers. The young plants are only slightly poisonous. Fatal cases exhibit spasms and convulsions.—*C. D. Marsh.*

2711. PAMMEL, L. H. Snow of the mountain. *Vet. Med.* 17: 647. 1922.—Replying to a question concerning *Euphorbia marginata*, it is stated that this plant has an acrid milky juice. The irritating and poisonous effects of several other species of *Euphorbia* are described.—*C. D. Marsh.*

2712. PAMMEL, L. H. Supposed poisonous mustards. *Vet. Med.* 17: 387. 1922.—Certain types of mustards cause bloat, but are not otherwise injurious.—*C. D. Marsh.*

2713. PAMMEL, L. H. Symptoms of wild cherry poisoning. *Vet. Med.* 17: 190-191. 1922.—Replying to a query in regard to the symptoms of poisoning by a species of *Prunus*, the author quotes Bergman, who is of the opinion that cases of poisoning are not characterized by high fever and are not the result of simple cyanide poisoning. Of 3 species investigated wild black cherry [*Prunus serotina* Ehr.] was most poisonous. Wilted leaves yield the maximum amount of prussic acid.—*C. D. Marsh.*

2714. PAMMEL, L. H. Will nightshade poison goslings? *Vet. Med.* 17: 467. 1922.—The several kinds of nightshade, *Solanum*, *Hyoscyamus*, and *Datura* are all poisonous. The author has had no experience with the effect of these on goslings.—*C. D. Marsh.*

2715. RUSSELL, G. A. The influence of methods of distillation on the commercial value of oil of American wormseed. *Jour. Amer. Pharm. Assoc.* 11: 255-262. *Fig. 1-2.* 1922.—Attention is called to the fact that if the producers of oil of American wormseed would make a change in the apparatus now in use, particularly as to size of pipe from the boiler into the retort so that sufficient steam could be driven through the apparatus to effect the completion of the distillation within 15 minutes, an oil could be secured complying with the requirements of the U. S. P. The author bases his statements upon a series of laboratory and field experiments. He also states the following conclusions: that "warming up" is bad practice; that

water should not be added to the retort but that the retorts should be drained from time to time; that the distillate received should be warm, since cooling the same causes a loss of oil.—*Anton Hogstad, Jr.*

2716. WEITS, R., et A. BOULAY. *Essai pharmacologique d'un glucoside cardiotonique extrait du Thevetia neriifolia*. [Effects of a glucoside from *Thevetia neriifolia*.] *Compt. Rend. Soc. Biol.* 87: 1105–1106. 1922.—The fruit of *Thevetia neriifolia* (*Cerbera thevetia*), indigenous to Central America but cultivated in Western Africa, yields a glucoside. Injections of 4 mgm. of this drug in dogs weighing 1 kgm. resulted in death within 1 hour through heart paralysis.—*J. Dufrénoy*.

GENERAL

2717. ANONYMOUS. [Rev. of: MAQUENNE, L. *Précis de physiologie végétale*. (Fundamentals of plant physiology.) (Collection Payot.) 175 p. Payot et Cie.: Paris, 1922 (see Bot. Absts. 12, Entry 733).] *Nature* 110: 177. 1922.—This is considered a good elementary text.—*O. A. Stevens*.

2718. [B., W. M.] *Biochemistry*. [Rev. of: MOORE, BENJAMIN. *Biochemistry: a study of the origin, reactions and equilibria of living matter*. vii+340 p., 6 fig. Edward Arnold & Co.: London, 1921.] *Nature* 109: 639–640. 1922.

2719. MARSHALL, C. E. *Microbiology—A text-book of microorganisms general and applied*. 3rd ed., xxviii + 1043 p., 2 pl., 200 fig. P. Blakiston's Sons & Co.: Philadelphia, 1921.—In this edition the most noteworthy change has been made by the addition of 3 chapters on the physiology of microorganisms, in which the general principles of physical and biological chemistry and cell mechanism are discussed in relation to these organisms. A better arrangement has been made by regrouping the chapters on food. The discussions on fermented foods and food poisoning have been amplified. Additional material is presented on special industrial fermented products, biological products, and the control of infectious diseases.—*S. R. Warner*.

2720. MOORE, BENJAMIN. *Biochemistry: A study of the origin, reactions and equilibria of living matter*. vii+340 p., 6 fig. Edward Arnold & Co.: London, 1921.—This work deals with the physiology, or work, of living matter, rather than with its structure, and it relates both to plant and animal life. The first 2 chapters express observations and thoughts that led to the experimental work described in the next 6 chapters. Chapter I is a consideration of the properties of the energy peculiar only to living matter and of the effects of artificial chemical and physical interference, many specific examples being included. The 2nd chapter reviews the various works on photosynthesis and considers the interrelations of living matter, also the energy of light, the idea being set forth that inorganic colloids activated by radiant energy are to be regarded as a stage in the formation of the organism. The remaining 7 chapters deal with the energy and chemical transformations in living matter and the products of this living matter, with which is combined a critical study of enzymatic activity and equilibria. The chapters giving experimental work are each summarized. The bibliography at the end of the book consists of 17 titles which are references to general monographs and to the author's previous publications. [See also Bot. Absts. 12, Entry 2718].—*L. J. Klotz*.

2721. OPPENHEIMER, CARL. *Grundriss der Physiologie. Erster Teil, Biochemie. [Outline of physiology. Part I. Biochemistry.]* 476 p. Thieme: Leipzig, 1919.—The book is divided into 2 general sections. The 1st is systematic in nature and deals with the various compounds encountered in the animal body in the order of their chemical complexity, giving in handbook fashion their general characteristics and tests, but without sufficient detailed data for use in the laboratory; each natural chemical group is concluded with notes on the physiology of the group. This section also includes notes on the various animal enzymes, taking each one up separately. The 2nd section deals with the chemical physiology of the various compounds, discussing food materials, the transportation of such materials, secretion and excretion, regulations of functions, and the chemistry of tissues. The standpoint is that of the animal physiologist, plant products being mentioned only incidentally. The entire presentation tends to be extremely concise and takes for granted a considerable knowledge of organic chemistry. It constitutes a comprehensive review of the field, but is neither a handbook nor a laboratory guide.—*A. F. Camp.*

2722. TAYLOR, W. W. *The chemistry of colloids and some technical applications.* 2nd ed., 332 p. Longmans, Green & Co.: London and New York, 1921.—This edition is practically the same as the 1st. A paragraph on alcogels has been added, and some of the more recent work of Einstein, Svedberg, Oswald, and others is cited.—*H. C. Young.*

DIFFUSION, PHYSICO-CHEMICAL PHENOMENA

2723. ANONYMOUS. *Soaps and proteins.* [Rev. of: FISCHER, M. H., G. D. McLAUGHLIN, and M. O. HOOKER. *Soaps and proteins: their colloid chemistry in theory and practice.* ix + 272 p. J. Wiley and Sons: New York; Chapman and Hall: London, 1921 (see Bot. Absts. 11, Entry 2996).] *Nature* 110: 70-71. 1922.—The reviewer regards the work as unsatisfactory, criticising especially 4 alleged defects, as follows: (1) Reasoning by analogy from the properties of soaps as necessarily indicative of the behavior of proteins; (2) ignoring the work of other investigators, especially the contributions on emulsions and froths; (3) ignoring such fundamental factors as surface and interface tensions, adsorption, and film formation; (4) supporting theories by atypical experiments.—*Mildred L. Johnson.*

2724. JOYNER, REGINALD ARTHUR. *The viscosity of cellulose. Part II. The lowering of the viscosity of cellulose by various reagents.* *Jour. Chem. Soc. [London]* 121: 2395-2409. 4 fig. 1922.—The viscosity of cellulose is decreased by treatment with NaOH. The temperature coefficient for a rise of 10°C. is about 1.6. KCl is specially notable among salts in increasing the absorption of NaOH by cellulose. This effect may be due to an increase in the OH-ion concentration, to raising the potential of the OH-ion, or it may result from a specific action on cellulose. The action of dilute acids, air, oxygen, hydrogen peroxide, and sodium hypochlorite on cellulose was also studied. Sixteen gm. of oxygen reacted with about 2100-2500 gm. of cellulose. "Raw silver" is not very soluble in cuprammonium solution but becomes so after digestion with dilute NaOH, which destroys the protein matter present, permitting the solvent to attack the cellulose.—*F. E. Denny.*

2725. MCBAIN, JAMES WILLIAM, and WILLIAM JOB JENKINS. *The ultrafiltration of soap solutions: Sodium oleate and potassium laurate.* *Jour. Chem. Soc. [London]* 121: 2325-2344. 1922.—An improved type of ultrafilter, designed for pressures up to 900 pounds per square inch and with a capacity of 250 cc., is described in detail. Its use gave quantitative information on many important problems regarding the condition of soap solutions, e.g., relative amounts of crystalloid and colloid present at any time, osmotic pressure, hydration, diameters of colloidal particles and membrane pores, composition of ionic micellae, etc. Soap, e.g., sodium oleate (NaOl), in true solution behaves as a crystalloid; but with increasing concentration increasing amounts of simple molecules (NaOl) become aggregated into neutral colloid particles (NaOl)_x; and increasing amounts of oleate ions (Ol') are aggregated without loss of electric charge to form colloidal particles known as ionic micellae (Ol')_n. It is believed that each ionic micella is formed by the union of at least 8 or 10 ions. By a suitable choice

of membrane and pressure, only crystalloid soap and its simple ions could pass through, the 2 colloidal forms, i.e., neutral colloid and ionic micella, being held back. Even the last 2 were separated by ultrafiltration. The diameters of the pores in any one collodion membrane were found to vary over a wide range. Thus, in 1 membrane 1 pore was $300\ \mu$; 2 were $150\ \mu$; 3, $90\ \mu$; 6, $75\ \mu$; 8, $60\ \mu$.—F. E. Denny.

2726. RUTTNER, FRANZ. Das electrolytische Leitvermögen verdünnter Lösungen unter dem Einflusse submerser Gewächse. I. [Electrolytic conductivity of dilute solutions as influenced by submerged plants.] Sitzungsber. Akad. Wiss. Wien [Math.-Naturwiss. Kl.] Abt. I. 130: 71-108. 3 fig. 1921 [1922].—*Elodea canadensis* was grown in distilled and sea water, and in various dilute solutions, such as CaNO_3 and $\text{Ca}(\text{HCO}_3)_2$, and the absorption of ions in light and darkness was followed by the electrical conductivity method. From experimental data giving the resistance in ohms, the conductivity is expressed in reciprocal ohms, and since in dilute solutions such as here employed the ratio of electrical conductivity to equivalent concentration is nearly constant, the ion changes may be expressed in terms of concentrations.—With plants growing in sea water a rhythmic rise and fall of conductivity was observed in the solution. With the advent of daylight the conductivity fell slightly for about an hour, then increased rapidly to a maximum about 3 hours after noon, following which it fell again to a minimum in the early evening; during the night a slow increase again took place. These changes are related to the breaking down of dissolved $\text{Ca}(\text{HCO}_3)_2$, in which sea water is rich, and the use of CO_2 in assimilation; as a result CaCO_3 is precipitated from solution, and the conductivity falls. During intensive assimilation CaCO_3 is further broken down by continual removal of HCO_3 ions, which are absorbed by the plant more rapidly than Ca ions. As a result CaCO_3 is partly converted into $\text{Ca}(\text{OH})_2$. This change is indicated also by the development of marked alkalinity in the solution during daylight, as shown by phenolphthalein. The rise is due to the higher equivalent conductivity of the hydroxide than of the carbonate. There is no diffusion of electrolytes from the plant. The decrease in conductivity in late afternoon is due to the reverse process—change from hydroxide to carbonate; the subsequent increase is due to accumulation of respired CO_2 during the night.—The rise in conductivity may be utilized to determine the effectiveness for photosynthesis of different kinds of light. In red light the changes in conductivity parallel those in white and are nearly as intense; in blue light there was a slight rhythm similar to that in white, while in darkness there was only a steady rise.—By the use of a bicarbonate solution of known CaCO_3 content the changes in concentration corresponding to certain conductivity values were determined and from these ratios the amount of CO_2 assimilated per hour and per gm. of dry weight of plant was calculated. In one instance this amounted to 5.2 mgm. CO_2 , while 11.9 mgm. of carbonate were precipitated. When natural brook water was used, the corresponding values were 8.0 mgm. CO_2 and 18.1 mgm. CaCO_3 . This would amount to the deposition of about 2 kgm. of chalk by an *Elodea* colony, the green weight of which is 100 kgm., each day of 10 hours of sunlight. The importance of this process in building up carbonate deposits is pointed out.—F. Weiss.

WATER RELATIONS

2727. FRITSCH, F. E. The moisture relations of terrestrial algae. I. Some general observations and experiments. Ann. Botany 36: 1-20. 2 fig. 1922.—The author is concerned with the problem of how subaerial algae are enabled without any special modification to often withstand prolonged periods of drought and to revive with astonishing rapidity when moisture conditions prevail. The amount of water absorbed by the algae *Pleurococcus Naegeli*, *Hormidium*, and *Zygnema ericetorum*, when moistened, is compared with that taken up by purely aquatic algae, such as *Spirogyra* and *Cladophora*, and also with cotton wool and soil. It was found that *Pleurococcus* absorbs even less water than soil, and that the aquatic algae take up more than the other 2 terrestrial algae studied. If then allowed to become air-dry, *Pleurococcus* reaches the dry state before either *Hormidium* or *Zygnema*. *Pleurococcus* is extremely sensitive to changes in the moisture content of the air, attributed by Fritsch to the power of its cell-wall to absorb readily any atmospheric moisture. The ter-

restrial algae have no conspicuous vacuoles. If allowed to dry under observation, *Pleurococcus* shows very little contraction, but *Hormidium* and *Zygnema* shrink appreciably. It is noteworthy that in *Hormidium* the cell-wall on drying falls into longitudinal striations observable in the fresh, moist filaments. In contrast with many really aquatic algae, the protoplast in the terrestrial algae examined does not shrink away from the wall when the cells dry in the air, a provision presumably important in the rapid transference of moisture, when in contact therewith, from the cell-wall to the protoplast. The osmotic pressure of the cell-sap of these algae was found to be considerable, and there is a striking correlation between the osmotic pressure and rate of drying; likewise the notable retention of moisture by the air-dry algae is related to the concentration of the sap.—*Nellie A. Carter*.

2728. KNIGHT, R. C. Further observations on the transpiration stomata, leaf water-content, and wilting of plants. *Ann. Botany* 36: 361-385. 1922.—By means of a modified recording potometer it was found that shortly before wilting there occurred a sudden increase in the stomatal aperture, amounting to as much as 40 per cent of its previous magnitude, which increase was accompanied by a simultaneous increase in the rate of transpiration. Wilting occurred when the water content of the leaves had decreased approximately 1 per cent. The water-content of leaves of different ages varied greatly. Diurnal changes of leaf water-content of the plants used in the experiments varied less than 2 per cent.—*Lionel E. Tisdale*.

2729. YOCUM, L. E., and A. L. BAKKE. Comparison of absorption occurring in corn stalk tissue and in prepared biocolloids. *Proc. Iowa Acad. Sci.* 27: 123-127. *Fig. 25.* 1920.—Masses of tissue cut from vigorous corn stalks and dried were compared with dried agar jelly and agar with 0.05 per cent of egg albumen. Rate and amount of absorption of fluids and increase in thickness and weight were measured. The curves for the 3 substances are very similar, but the values for the corn tissue are all much smaller than those for the other colloids.—*H. S. Conard*.

MINERAL NUTRIENTS (SALT RELATIONS)

2730. DUFRÉNOY, JEAN. The biological significance of selective adsorption. *Amer. Midland Nat.* 6: 159-165. 1920.—Base-adsorbent colloids are found in the cell walls and in most of the granules of the cytoplasm. Nucleoplasm is generally acid-adsorbent except in pathological cases, where it may become base-adsorbent. Competition for bases is constantly going on between the basophilous colloids in the plant and those in the habitat, which may result in a considerable accumulation of bases in the plant tissues with a serious loss in the habitat.—*Sister M. Ellen*.

2731. GERICKE, W. F. "Magnesia injury" of plants grown in nutrient solutions. *Bot. Gaz.* 74: 110-113. 1922.—Experiments are here reported which have a bearing on the problem of leaf tip abscission in wheat plants when in nutrient solutions containing a relatively high concentration of certain salts. It was found that the injury sustained by the seedlings when grown in a solution of potassium salts was greatest with K_2SO_4 and least with KH_2PO_4 . With calcium salts no injury whatever resulted. Excessive abscission resulted with both $Mg(NO_3)_2$ and $MgSO_4$ but none with $MgHPO_4$. Two conclusions are apparent if the injury in the above cases may be regarded as physiologically the same. (1) The lack of calcium in the nutrient media may induce the injury; this is indicated by the results with K_2SO_4 , in which case Mg was not present. (2) The presence of phosphorus tends definitely to prevent the injury, for when the phosphate ion is associated with magnesium or with potassium (and calcium absent) no injury results.—*B. W. Wells*.

2732. GERICKE, W. F. Water culture experimentation. *Science* 56: 421-422. 1922.—This paper reports experiments with wheat plants grown in a series of single-salt solutions. The set of plants that grew best was kept for 4 days in KNO_3 , 1 day in $CaSO_4$, and 1 day in $MgHPO_4$, then returned to KNO_3 , etc. The growth was as good as that of controls in the

complete balanced solution of these 3 salts. The solutions were 0.01 molecular. A trace of an iron salt was added to each solution used.—*C. J. Lyon.*

2733. HERBERT, D. A. [Rev. of: TRELEASE, SAM F., and BURTON E. LIVINGSTON. Continuous renewal of nutrient solution for plants in water-culture. *Science* 55: 483-486. 1922 (see Bot. Absts. 11, Entry 4620).] *Philippine Agric.* 11: 23. 1922.

2734. LATSHAW, W. L. Report on sulphur and phosphorus in the seeds of plants. *Jour. Assoc. Official Agric. Chem.* 6: 468-470. 1922.—The Parr peroxide bomb was used in determining the sulphur and phosphorus content of several plant materials. Results were very favorable and the method is fully described.—*F. M. Schertz.*

2735. LOEB, JACQUES. Chemical character and physiological action of the potassium ion. *Jour. Gen. Physiol.* 3: 237-245. 1920.—Data obtained from experiments with eggs of *Fundulus* and sea urchins are presented which indicate that the antagonistic behavior of the K ion in salt solutions is due not to any trace of radioactivity, but to the purely chemical character which is determined by position in the periodic system. Li and K ions which are on opposite sides of the Na ion in the periodic table seem to deviate in their physiological action in opposite directions from Na. Tolerance to Li ions in solution with Na and other salts was increased 500 per cent and more by substituting elements on the other side of Na, that is, K, Rb, and Cs, for part of the Na.—*Otis F. Curtis.*

2736. PATCHOVSKY, N. Über eine Möglichkeit des aussernormalen Entstehens von pflanzlichem Kalziumoxalat. [Artificial formation of calcium oxalate crystals in plant cells.] *Biol. Centralbl.* 39: 481-489. 1919.—Previous work of the author showed that plants in which no formation of calcium oxalate crystals takes place lack oxalic acid in the cell sap. Investigations here reported seem to prove that in such cases exposure to weak solutions of potassium oxalate of less than fatal toxicity resulted generally in a more or less pronounced formation of calcium oxalate crystals, and that the amount of crystal formation was related to the toxic effect of the oxalate solution on the plant under experiment.—Leaves of *Mniun* and *Fanaria*, of *Eloëa densa*, *Nasturtium*, and *Ceratophyllum*; moss protonema, *Vaucheria*, and *Spirogyra* were cultivated in close covered glass dishes of 30 cc. capacity. Dilutions of 1, 2, and 3 per cent of potassium oxalate in water were employed and as the experiments were performed in winter the photosynthate deficit was supplemented by a 5 per cent cane sugar solution. Specimens used showed notable differences in resistance to the toxic effect of the oxalate solution. The most resistant—moss protonema—failed to show calcium oxalate crystals. In the more sensitive *Spirogyra*, which normally exhibits crystal formation, exposure to 1 per cent potassium oxalate solution with 10 per cent cane sugar resulted in a notable increase of crystals. It is concluded that this formation of calcium oxalate crystals indicates a means by which plant cells become protected against the toxic effects of oxalic acid, in that the calcium salt of the cell sap combines with the oxalic acid to form an insoluble salt.—*William L. Bray.*

2737. PFEIFFER, TH. Über den Einfluss des Kalk-Magnesia-Verhältnisses auf das Wachstum der Pflanzen. [Influence of the calcium-magnesium ratio upon the growth of plants.] *Jour. Landw.* 69: 1-3. 1921.—This is in reply to Oskar Loew.—*F. M. Schertz.*

[The behavior of different plants toward difficultly soluble phosphates.] *Jour. Landw.* 69: 165-183. 1920.—Plants differ physiologically and are characterized by their different powers to act upon difficultly soluble phosphates.—*F. M. Schertz.*

2739. RIPPEL, AUGUST. Untersuchungen über die Mobilisation der Aschenbestandteile und des Stickstoffs in Zweigen beim frühjährlichen Austreiben. [Investigation on the mobilisation of the ash constituents and nitrogen in twigs in spring elongation.] *Biochem.*

Zeitschr. 113: 125-144. 1921.—Rippel finds that as leaves develop in the spring, P, K, Mg, Na, and N are transported from the twigs to the leaves, while Ca, S, and Cl are not so transported. This corresponds with the transportation from the leaves into the stem in the fall. The elements so transported were found to have occurred almost exclusively in the twigs in organic combinations. When the twigs were placed in nutrient solutions lacking 1 essential element at a time it was found that the element lacking in the nutrient solution was dissolved and transported to a greater extent than when the twigs were placed in distilled water. This was true of all elements transported. The lack of carbohydrates was not reached as soon as the lack of mineral salts. Due to the inability of the twigs to transport calcium, the leaves suffered in their development in the same way that seedlings without calcium suffer.—*F. G. Gustafson.*

2740. TURNER, THOMAS WYATT. Studies of the mechanism of the physiological effects of certain mineral salts in altering the ratio of top growth to root growth in seed plants. *Amer. Jour. Bot.* 9: 415-445. 1922.—Previous work on the factors determining the ratio between tops and roots of plants is reviewed. Concentration of the nutrient solution has been thought to influence this ratio, but the author suggests that this result may be due instead to deficiency in one or more of the mineral nutrients. He therefore studied the effect of nitrate ions on the relative behavior of tops and roots in certain plants. In 3 nutrient solutions the concentration of nitrate salts was made low, medium, and high, respectively, the solutions being otherwise identical. With barley and corn, the ratio of tops to roots increases significantly as the nitrate concentration of the solution is increased. The actual dry weight of roots is greatest in the low nitrate solution and of tops in the high. In another set of solutions where the amount of nitrate was left as in the previous experiment, but where the total concentration of the solution less nitrate was greatly altered, essentially the same results were secured, thus indicating that nitrate concentration rather than total concentration was the determining factor in the top-root ratio. Hydrogen-ion concentration was also found to be without effect. With flax, unlike barley and corn, there was no change in the ratio as the nitrate concentration was altered. In all experiments the efficiency of the solution used, as judged by total dry weight produced, was not greatly different.—To determine the direct effect of nitrates on root growth, root tips were grown in nutrient solutions with a supply of sugar; it was found that nitrates increased root growth in all cases. The relation of dry weight to green weight was found to be materially different in certain cases, and it is pointed out that neither dry weight nor length of root is a safe measure of growth. The increased ratio of tops to roots which results from increased nitrate concentration may be due to the increased use of carbohydrates by the tops because of the greater growth there which has been stimulated by the nitrogen. This results in a decrease in the supply of carbohydrates for the roots, which may bring about an absolute or at least a relative reduction in root growth.—*E. W. Sinnott.*

PHOTOSYNTHESIS

2741. CERIGHELLI, RAOUL. Influence de l'anhydride carbonique sur le développement des plantes—emploi de CO₂ comme engrais atmospherique. [Influence of carbon dioxide upon the development of plants—the use of CO₂ as an atmospheric fertilizer.] *Ann. Sci. Agron. Française et Étrangère* 38: 68-75. 1921.—The literature on the subject is briefly reviewed, attention being drawn especially to the work of Demoussy, Brown and Escombe, Cummings and Jones, and Riedel. The author draws conclusions as follows: (1) the enrichment of the air with CO₂ considerably increases the development of plants, whether in the greenhouse or open fields; (2) the CO₂ used should be very pure or at least unmixed with toxic gases. The residual gases of furnaces may be used, and it is quite likely that the CO₂ of fermentation industries may be suitable.—More researches are necessary to put the utilization of the gas on a sound practical basis.—*A. B. Beaumont.*

2742. GAIL, FLOYD W. Photosynthesis in some of the red and brown algae as related to depth and light. *Publ. Puget Sound Biol. Sta.* 3: 177-193. 1922.—A series of experiments is

reported giving the amounts of photosynthesis in a number of red and of brown algae, using the Winkler method for the determination of the oxygen evolved. The results indicate that certain species of red algae, in nature usually deeply submerged, exhibit maximum photosynthesis at 15 m. approximately. Certain species which occur both deeply submerged and near the surface, usually somewhat different in color in the 2 habitats, have their maxima at different depths, the deeper forms at about 15 m., the shallower form at 1-8 m.—Among the brown algae the maximum photosynthesis in *Fucus evanescens* is at 1 m.; in *Costaria costata*, about 8 m., in *Desmarestia ligulata*, about 15 m.—Those algae growing 3 or more m. below the surface show maximum photosynthesis nearer the surface in cloudy weather (or under a roughened surface) than they do in clear weather and under a smooth surface. Algae growing practically at the surface show reduced amounts of photosynthesis when submerged more deeply. There seems to be a rather definite relation between the maximum photosynthesis and the habitat of species experimented upon. The lower limit at which appreciable photosynthesis takes place in both the red and the brown seaweeds in Puget Sound is about 35 m.—*T. C. Frye*.

METABOLISM (GENERAL)

2743. BODMER, HELEN. Die Reservestoffe bei einigen anemophilen Pollenarten (Vorläufige Mitteilung). [The reserve materials of certain anemophilous types of pollen. (Preliminary contribution.)] Vierteljahrsschr. Naturforsch. Ges. Zürich 66: 339-346. 1921.—This paper deals with the starch, fat, and water content of certain monocot and dicot pollen-grains, and the taking up of food materials from the substratum during the growth of the pollen-tube.—*John H. Schaffner*.

2744. CAJORI, F. A. The use of iodine in the determination of glucose, fructose, sucrose and maltose. Jour. Biol. Chem. 54: 617-627. 1922.—A method has been devised for the quantitative determination of glucose, fructose, and sucrose, where these sugars occur together and in small quantities. Results suggesting that the method may be extended to include maltose are given. It is pointed out that in applying this method to plant extracts containing other compounds in addition to the sugars the accuracy of the results will depend on the freedom of the solution analyzed from reducing substances other than sugars, or compounds that will react with iodine.—*G. B. Rigg*.

2745. COMBES, RAOUL. La formation des pigments anthocyaniques. [The formation of anthocyanic pigments.] Compt. Rend. Acad. Sci. Paris 174: 240-242. 1922.—Studies were made with leaves of *Ampelopsis hederacea*. The experiments of Jonesco, who claimed that the appearance of the red pigment was due to an oxidation process, were repeated. The author disagrees with the conclusions of Noack and of Jonesco, and claims that they did not take sufficient account of the fact that these compounds are derivatives of γ -pyrane.—*C. H. Farr*.

2746. FEHER, DANIEL. Über die Abscheidung von Harzbalsam auf den jungen Trieben unserer einheimischen Populus-Arten. [The separation of resin in young shoots of our native species of Populus.] Beih. Bot. Centralbl. I Abt. 39: 81-103. 1922.—The secretion of resin is a common occurrence in the Populus species investigated. It is found in small quantities in *P. alba*, *P. tremula*, and *P. canescens*, but in larger quantities in *P. pyramidales*, *P. balsamifera*, and *P. canadensis*.—The secretions take place in the glandular teeth of the foliage leaves, the stipules, and the bud scales. The secretion always occurs in the modified prism-shaped epidermal cells. It passes immediately to the outer surface, or it lifts the cuticle and penetrates between it and the cell membrane. The secretion is resin (Harzbalsam) and contains no gum (caoutchouc).—*L. Pace*.

2747. FORSTER, M. O. The laboratory of the living organism. Sci. Monthly 13: 301-308. 1921.—This is a summary of the address of the president of the Chemical Section of the British Association for the Advancement of Science dealing, among many purely chemical matters,

with certain bacteriological and technological advances, such as: Buchner's zymase and the later discoveries; the chemical work done by yeasts, molds, and bacteria; the mechanism for utilizing nitrogen and carbon; whether chlorophyll is protective and the result of photosynthesis, or the agent of this process; and many applications of such work.—*L. Pace.*

2748. HEYL, FREDERICK W. The phytosterols of ragweed pollen. *Jour. Amer. Chem. Soc.* 44: 2283-2286. 1922.—The following phytosterols were found in the unsaponifiable portion of the ragweed pollen: "ambrosterol," $C_{26}H_{44}O$, melting at $147-149^{\circ}C.$, a phytosterol with the formula $C_{27}H_{46}O$; also cetyl alcohol, octodecyl alcohol, and traces of hydrocarbon. There is also some evidence of a hydroxyphytosterol.—*J. M. Brannon.*

2749. HAWORTH, WALTER NORMAN, and GRACE CUMMING LEITCH. The constitution of the disaccharides. Part VI. The biose of amygdalin. *Jour. Chem. Soc. [London]* 121: 1921-1929. 1922.—The paper concerns the structural formula of amygdalin extracted from bitter almonds, and in particular the nature of the sugar associated with mandelonitrile in the glucoside.—*F. E. Denny.*

2750. HERZFELDER, HELENE. Beiträge zur Frage der Moosfärbungen. [Moss pigments.] *Beih. Bot. Centralbl. I Abt.* 38: 355-400. 1921.—The colors in mosses, like those of higher plants, are due to chromatophores and cell sap; but the most important moss coloring is due to material in the cell wall. This latter material falls into 2 groups, one giving the anthocyan reaction, the other the phlobaphene. This wall-coloring material cannot be stored food, for it could not be used. The disappearance of the color was not observed except in *Orthothecium* where there is a possibility of its further use. The blue color of *Metzgeria fruticulosa* and *M. boliviana* is post mortem.—*L. Pace.*

2751. HICKMAN, KENNETH, CLAUDE DEVEREUX and REGINALD PATRICK Linstead. A modified methyl-orange indicator. *Jour. Chem. Soc. [London]* 121: 2502-2506. 1 fig. 1922.—In titrating with methyl-orange the end-point is not sharp, but by adding "a suitable screening dye there is a period during the acidification when the amounts of red, green, and blue transmitted are visually equal, so that the solution appears white or neutral grey. The colour change is, therefore, green-neutral grey-magenta, that is, from one colour, through white, to a supplementary colour,—a change to which the eye is most sensitive." The mixed indicator recommended consists of 1 part of methyl-orange to 1.4 parts of xylene cyanole FF dissolved in 500 parts of 50 per cent alcohol. The end-point is at $p_H = 3.8$. The indicator is valuable, for example, in the estimation of mixed hydroxide and carbonate by the double end-point method. Results equal to those obtained in daylight were obtained with a 100-watt, gas-filled, "daylight" lamp with a blue glass bulb.—*F. E. Denny.*

2752. HOLBØLL, SVEND AAGE. Untersuchungen über I. Bangs Mikromethode zur Bestimmung von Traubenzucker. [Investigation on I. Bang's new micromethod of determining grape sugar.] *Biochem. Zeitschr.* 113: 200-209. 1921.—A brief description of Bang's new method for determining glucose is given. This is followed by a verification of the method through experiments in which various amounts of sugar were used. The writer finds that there is a constant relation between the amount of potassium iodate reduced and the amount of glucose, irrespective of the concentration of the glucose. This constant was found to be 0.265 cc. of 0.01 N KIO_3 per 0.1 mgm. of glucose. To calculate the amount of glucose in an unknown solution he used the following equation: $x = 2.00 - n - a \div p$, where n is the number of cc. of 0.01 N KIO_3 reduced, a the number of cc. of 0.01 N thiosulphate used to titrate the remaining KIO_3 , and p the constant (0.265). This equation gives the glucose in 0.1 mgm. amounts.—*F. G. Gustafson.*

2753. IRMIN, GUIDO. Zur Kenntnis der Stoffverteilung bei einigen Iris-Arten, besonders in ihren Blättern. [The distribution of material in some species of Iris, especially in the leaves.] *Beih. Bot. Centralbl. I Abt.* 39: 152-205. 1922.—A brief statement is made as to

papillae, bundles, chlorophyll, parenchyma, spaces, anthocyanin, starch, tannins. This is followed by records of individual investigations on leaf, rhizome, and root of *Iris biglumis*, *I. Gueldenstaediana*, *I. songarica*, *I. spuria* var. *sogdiana* and var. *notha*, *I. sibirica*, *I. ruthenica*, *I. japonica*, *I. foetidissima*, *I. versicolor*, *I. Pseudoacorus*.—Seasonal variations are described. All species investigated have tannin either diffused or in idioblasts or in both conditions in the outer and inner epidermis. Its distribution in the mesophyll, the bundles, the rhizomes, and the roots is given. As the leaf continues elongation, from March or April to July or August, the tannin content gradually increases. The idioblasts appear typically first at the base and next at the tip and spread from these 2 areas.—*L. Pace*.

2754. JACOBS, W. A., and M. HEIDELBERGER. **Strophanthin. I. Strophanthidin.** Jour. Biol. Chem. 54: 253-261. 1922.—Strophanthin is a glucoside which on hydrolysis yields a crystalline substance, strophanthidin, and reducing sugars. Strophanthidin ($C_{23}H_{47}O_6$) is a component of a number of glucosides which possess a characteristic action on the heart and occur in different plants.—*G. B. Rigg*.

2755. JAMMIESON, GEORGE S., WALTER F. BANGHAM, and DIRK H. BRAUNS. **The chemical composition of peanut oil.** Jour. Amer. Chem. Soc. 43: 1372-1382. 1921.—Two samples of peanut oil were studied, one a Spanish type grown in South Carolina and the other a Virginia type grown in Virginia. A comparison of these 2 with respect to the percentages of the different fatty acids contained in the glycerides is given below, the figure given first in each case referring to the Spanish type and the other to the Virginia type: oleic acid, 52.9 and 60.6; linolic acid, 24.7 and 21.6; palmitic acid, 8.2 and 6.3; stearic acid, 6.2 and 4.9; arachidic acid, 4.0 and 3.3; and lignoceric acid, 3.1 and 2.6 per cent. Of unsaponifiable matter there was respectively 0.2 and 0.3 per cent.—*J. M. Brannon*.

2756. KENNEDY, CORNELIA, and L. S. PALMER. **Yeast as a source of vitamine B for the growth of rats.** Jour. Biol. Chem. 54: 217-232. 1922.—The results do not support the general belief that yeast is an unusually valuable source of the growth-promoting vitamine B, or that it can be accepted as a standard product in experiments in which a vitamine B preparation is required.—*G. B. Rigg*.

2757. LIPPMAN, E. O. VON. **Einige pflanzenchemische Beobachtungen.** [Some observations on the chemistry of plants.] Ber. Deutsch. Chem. Ges. 54: 3111-3114. 1921.—The presence of mannose, succinic acid, cane sugar, and "huminstoffe" in certain plants is discussed.—*Henry Schmitz*.

2758. MACDONALD, MARGARET B. **The synthesis of water-soluble B by yeast grown in solutions of purified nutrients.** Jour. Biol. Chem. 54: 243-248. 1922.—It would seem from the results obtained by feeding 5 varieties of yeast that, so far as its content of water-soluble B is concerned, yeast grown in solutions of purified nutrients is much like yeast grown in other media. The results obtained with the 5 varieties of yeast tend to make general the conclusions reached by other workers for 1 variety, the conclusion being that yeast is capable of synthesizing water-soluble B when grown in a nutrient solution of the necessary mineral salts (including ammonium chloride) and cane sugar.—*G. B. Rigg*.

2759. MALFITANA, G., et CATOIRE. **L'amylocellulose considérée comme composé d'acide silicique et d'amylose.** [Amylocellulose considered as a compound of silicic acid and amylose.] Compt. Rend. Acad. Sci. Paris 174: 1128-1130. 1922.

2760. MAMELI, EVA. **Estudios biológicos sobre el pólen.** (Trabajo preliminar.) [Preliminary report on the study of pollen.] Mem. Soc. Cubana Hist. Nat. "Felipe Poey" 4: 45-77. 1922.—Notes are given on the composition of the pollen in 353 species from 80 families of plants. Of the species studied 63 per cent have oily pollen at maturity and the remaining 37 per cent have pollen classed as starchy.—*J. A. Faris*.

2761. MASTERS, HELEN. Reactions of cellulose with sodium chloride and other neutral salt solutions. Part I. Preliminary survey. Jour. Chem. Soc. [London] 121: 2026-2034. 1922.—Results were obtained that were not in accordance with the generally accepted belief that cellulose is without action on dilute solutions of neutral salts. Neutral sodium chloride, when passed through cotton, came out acid, the amount obtainable from 200 cc. of $\frac{N}{10}$ NaCl and 10 gm. of cotton being equivalent to about 4.0 mg. of HCl. When the cotton which had been treated with NaCl was subsequently washed with water the leachings came out alkaline, the amount of alkali obtained in this way being about equivalent to the acid resulting from the original treatment with NaCl. Purified asbestos when treated in the same way did not liberate acid or alkali. Preliminary experiments with wool gave results the reverse of those obtained with cotton. Data on salts other than NaCl are given. Further experiments are planned to give information on the nature of the changes involved in these reactions.—F. E. Denny.

2762. ORTON, C. R., E. V. MCCOLLUM, and N. SIMMONDS. Observations on the presence of the antineuritic substance, water-soluble B, in chlorophyll-free plants. Jour. Biol. Chem. 53: 1-6. 1922.—The onion root [bulb] contains a certain amount of water-soluble B. This fact is believed to warrant the conclusion that water-soluble B is not concerned with the structure of the chloroplast. The mushroom *Agaricus campestris* proved to be a good source of this vitamin. Dodder, *Cuscuta Gronovii*, proved toxic and caused the death of the experimental animals. Indian-pipe, *Monotropa uniflora*, gave inconclusive results.—G. B. Rigg.

2763. PALMER, L. S. Carotinoids and related pigments. 316 p., 2 pl. The Chemical Catalog Co., Inc.: New York, 1922.—The distribution and terminology of carotinoids are discussed in a general way. These red, orange, and yellow pigments extractable by fat solvents are found abundantly distributed in the plant world from bacteria to the highest phanerogams, in the animal world from protozoa to man. In a brief chronological review are given the results accomplished by the various workers towards determining the presence of carotinoids in phanerogams. This review is carried out under several subheads, such as carotinoids in roots, in chloroplastids, in etiolated leaves, in flowers, in fruits, in seeds and grains.—The cryptogams are abundantly characterized by these pigments, especially the algae and fungi. The study of carotinoids in bacteria is practically an unexplored field.—Some discussion is devoted to the presence of pigments in vertebrates and invertebrates. The chemical relations between carotinoids in plants and animals are given in detail. The consensus of opinion is that a chemical relation exists between plant and animal pigments, but they are not identical. The biological relation between plant and animal carotinoids is brought out by many experiments and observations contributed or cited by the author. Methods are given for the isolation of carotin from carrots, green leaves, and animal fat; for the isolation of xanthophyll from egg yolk and green leaves; also for lycopin from tomato and fucoxanthin from Phaeophyceae. General properties and methods of identification of carotinoids are explained, such as, crystallization, solubility, and spectroscopic analysis. Likewise, quantitative estimations of the various pigments are given.—The last chapter is devoted to a summation of the various theories concerning the possible functions of the carotinoids in plants and animals.—Grace E. Howard.

2764. TSCHIRCH, A. Besitzt die Pflanze Hormone? [Does the plant have hormones?] Vierteljahrsschr. Naturforsch. Ges. Zurich 66: 201-211. 1921.—The author compares plant vitamins with animal hormones and believes that vitamins play an important rôle in the plant organism. He also calls attention to such facts as the prolongation of the blooming period in orchids when pollination does not take place. Certain extracts of orchid pollen have the power to shorten the blooming period, as does pollination with living pollen, and seem to be of the nature of hormones. The accumulation and digestion of foods in storage organs, etc., may be due to the action of hormones. Hormones are of first importance as activators of enzymes. A difficulty in the comparison of the reactions in plant and animal bodies lies in the

fact that plants have no blood-vascular system. Passage of the hormones from cell to cell or through the vascular system, especially through the sieve-tubes, is conceivable. It is also possible that the hormone is not transferred but that it arises at the given point through a reaction. Hormones are considered to be chemical substances both organic and inorganic. The reaction might be considered as physical, for example an electrical stimulus; but the author points out that every stimulus must be resolved ultimately into a chemical reaction.—*John H. Schaffner.*

METABOLISM (NITROGEN RELATIONS)

2765. GROENEWEGE, J. Ueber die Denitrifikation mit Ameisensäuren Salzen und den Einfluss des Kation auf diesen Prozess. [Concerning denitrification with formic-acid salts and the influence of the cation on this process.] Dept. Landb. Nijv. en Handel (Nederland.-Indië) Alg. Proefsta. Landb. Mededeel. 7. 22 p. 1921.

2766. LIPMAN, C. B. Does nitrification occur in sea water? *Science* 56: 501-503. 1922.—The writer reviews the meager evidence as to the occurrence and activity of nitrifying bacteria in the open sea and near land surfaces. Recent experiments have proved that such bacteria are absent from open sea water though calcareous sand, taken from under open sea water, is found to "harbor vigorous nitrifying organisms."—*C. J. Lyon.*

2767. LIPMAN, C. B., and J. K. TAYLOR. Proof of the power of the wheat plant to fix atmospheric nitrogen. *Science* 56: 605-606. 1922.—Analyses of wheat plants grown in water cultures ("Shive's best" solution) prove that there is a gain of nitrogen from the air of at least 13-21 per cent of the total nitrogen found in the plant. Experiments with other plants are in progress and a full account of the work is promised.—*C. J. Lyon.*

2768. MAY, C. E., and E. R. ROSE. The tryptophane content of some proteins. *Jour. Biol. Chem.* 54: 213-216. 1922.—A new colorimetric method for the determination of tryptophane has been devised. The per cent of tryptophane in the plant proteins mentioned was found to be as follows: gliadin 1.05, glutenin 1.80, edestin 1.50, phaseolin 0.80, maize gluten 1.08, legumin 1.05, zein 0.00.—*G. B. Rigg.*

2769. WETTSTEIN, FRITZ VON. Das Vorkommen von Chitin und seine Verwertung als systematisch-phylogenetisches Merkmal im Pflanzenreich. [Occurrence of chitin in plants and its significance as a phylogenetic and systematic character.] *Sitzungsber. Akad. Wiss. Wien [Math.-Naturwiss. Kl.] Abt. I.* 130: 3-20. 1921 [1922].—Knowledge of the occurrence of chitin as a compound of the cell wall is largely due to van Wisselingh but is highly incomplete, particularly as regards its distribution among the lower thallophytes. The present is a survey of the occurrence of chitin in plants representative of the lowest to the highest orders.—The microchemical detection of chitin depends on its conversion into chitosans by hot lye; the presence of chitosan is indicated by a red violet coloration upon treatment with a solution of I in KI and a dilute acid. Other tests for chitosans, and the chemical reaction of chitin, are described.—The following conclusions on the distribution of chitin are presented: (1) The Myxomycetes (except *Plasmodiophora*) are sharply distinct from other plant groups in the presence of keratin and other protein substances in the cell wall; cellulose also may be present, but chitin is absent. (2) The Cyanophyceae and Schizomycetes, including Chlamydoacteriaceae, possess cell walls in which pectin-like substances predominate, but chitin is absent. (3) Among the euthallophytes there is evident a general differentiation even in the primitive forms into a line with chitinous membranes (the fungi) and one with cellulose (and modified cellulose) membranes (the algae). The Chlorophyceae without exception lack chitin—true even of heterotrophic forms; the cell walls in the Rhodophyceae and Phaeophyceae contain characteristic polysaccharides neither cellulose nor chitin. The Ascomycetes (except yeasts and Laboulbeniales) and the Basidiomycetes possess chitin or chitin-like substances to the complete exclusion of cellulose. Among the Archimycetes and *Phycomyces* there is a sharp differentiation into chitin- and cellulose-possessing forms, the 2 cell wall

constituents being always mutually exclusive. The Synchytriaceae and the Zygomycetes possess chitin, the Oomycetes without exception lack it. The presence or absence of chitin in the cell wall therefore corresponds in a broad way with morphological distinctions.—*F. Weiss.*

METABOLISM (ENZYMES, FERMENTATION)

2770. BAKER, JULIAN LEVETT, and HENRY FRANCIS EVERARD HULTON. Amylases of the cereal grains. The "insoluble" amylase of barley. *Jour. Chem. Soc. [London]* 121: 1929-1934. 1922.—Extracting ungerminated cereals with cold water does not remove all of the amylase that is present; but a 2nd yield of amylase firmly attached to some cell constituent can be obtained by various treatments, among them by digestion with papain. This indicated a connection with proteins; and the authors' experiments related to determining with what group of proteins the additional amylase was associated. Barley seed-powder was successively treated with solvents chosen to eliminate different classes of proteins; water removed albumins and soluble amylase, NaCl solution removed edestin, and alcohol removed hordein. Portions of the 3 residues were autodigested with papain and the filtrate tested for amylase. The insoluble amylase was found to be associated with the alcohol-soluble group (hordein); but papain could not liberate amylase from hordein itself, nor from a seed-powder that had been heated to destroy previously existing enzyme. Hence the additional amylase did not arise as a cleavage-product from a protein, but from a "pre-existent insoluble enzyme complex."—*F. E. Denny.*

2774. KÖHLER, E. Weitere Beiträge zur Physiologie der Hefe. [Physiology of yeast.] *Biochem. Zeitschr.* 111: 17-29. 1920.—The fermentation of 4 per cent maltose by yeast was measured by the number of CO₂ bubbles given off in $\frac{1}{2}$ minute. A 1st maximum rate was reached in 13 minutes, followed by a minimum 4 minutes later, and a 2nd maximum 23 minutes after that. Six hours later fresh maltose solution was added and the curve was repeated: 1st maximum in 3 minutes, minimum 19 minutes later, and 2nd maximum after an interval of 21 minutes. Increase in the rate is thought to be the result of enzyme activation by the sugar; decrease after the 1st maximum, a result of enzyme consumption in excess of activation; and the decrease after the 2nd maximum, a response to the decreasing concentration of sugar.

Fermentation is considered a type of assimilation, and the enzymatic reaction is thought to occur in the outer regions of the yeast plasma.—*H. D. Hooker, Jr.*

2775. MOLLIARD, MARIN. Sur une nouvelle fermentation acide produite par le *Sterigmatocystis nigra*. [Concerning a new type of acid fermentation caused by *Sterigmatocystis nigra*.] *Compt. Rend. Acad. Sci. Paris* 174: 881–883. 1922.—It has previously been shown that the Mucedineae under certain conditions can change sugar to citric acid or to oxalic acid. Citric acid is formed if the medium is low in nitrogen, and oxalic acid is produced if it is low in phosphorus salts. There is evidence here presented that a 3rd acid may sometimes be formed. Under certain special conditions there is formed an acid which gives Berg's reactions for acid-alcohols.—*C. H. Farr.*

METABOLISM (RESPIRATION, AERATION)

2781. B., W. E. Root respiration. [Rev. of: CLEMENTS, F. E. *Aeration and air content: the rôle of oxygen in root activity.* Carnegie Inst. Washington Publ. 315. 183 p. 1921 (see Bot. Absts. 11, Entry 1950).] *Nature* 110: 58–59. 1922.

ORGANISM AS A WHOLE

2782. BRANDL, MAX. Über die Brauchbarkeit pflanzlicher Ersatzmittel des Fleischwassers zur Herstellung von Bakteriennährböden. [The utility of plant substitutes for meat extract in the preparation of bacterial culture media.] Dissertation. 6 p. Munich (Tierärztl. H.), 1920.

2783. BUCHNER, PAUL. Tier und Pflanze in intrazellulärer Symbiose. [Animal and plant in intracellular symbiosis.] 464 p., 2 pl., 103 fig. Gebrüder Borntraeger: Berlin, 1921.—

The volume is essentially a compilation of the data pertaining to the subject, written with the object, as stated by the author in his preface, of showing the need of a fresh consideration and study of the question of the intracellular symbiosis between animals and plants.—The subject matter is arranged under 7 heads, the first 4 grouped according to the natural classification of the invertebrates, dealing with symbiosis in the Protozoa, the sponges, the Coelenterata, the worms, the Bryozoa, the Echinodermata, the Mollusca, the Tunicata, and the Insecta. Besides *Zoochlorella* and *Zooxanthella* the symbionts discussed include various fungi and bacteria. The 5th subhead treats of light-producing symbiosis in the lower animals. The 6th subhead is entitled The Errors in the Investigation of Symbiosis, and in it (as elsewhere incidentally) are discussed the relations of mitochondria. The last subhead embodies the author's concluding remarks.—The volume is abundantly illustrated and contains numerous original figures, particularly in that section dealing with the insects. The index is ample and the bibliography contains approximately 600 titles, principally from zoological contributions.—*Carl Epling.*

2785. GROENEWEGE, J. Over de oorzaak van rustiness op rubber van *Hevea brasiliensis*. [On the cause of rustiness on Hevea rubber.] Dept. Landb. Nijv. en Handel (Nederland.-Indië) Alg. Proefsta. Landb. Mededeel. 11. 20 p., 1 pl. 1921. [With English summary.]—The Saccharomycetes and *Oidium* which cause the "rusty" coating on sheet rubber obtain their carbon and nitrogen from protein serum constituents, with the exception of the most important organism *Torula heveanensis* n. sp., which can also utilize the quebrachite. The amount of fermentable sugars in the rubber is insignificant. Freshly rolled and sterilized rubber becomes badly rusted in 24 hours. Dissolving out the water-soluble contents under aseptic conditions does not prevent rustiness, but soaking in the presence of bacteria results in the solution and removal of the proteins as well as the quebrachite and sugars, and prevents subsequent rustiness. Rubber once dried undergoes an irreversible loss of permeability; this prevents inward diffusion of proteolytic enzymes and outward diffusion of soluble substances, so that development of the rustiness organisms on the surface can not take place. Certain other characters of rubber are explained on the basis of irreversible permeability change.—*Carl Hartley.*

2786. PFOTENHAUER, CHARLOTTE, TH. PFEIFFER, und A. RIPPEL. Über den Verlauf der Nährstoffaufnahme und Stoffherzeugung bei der Gerste—bezw. Bohnenpflanze. [The course of food absorption and the increase in dry matter of the barley or bean plant.] Jour. Landw. 69: 137-162. 1920.—The production of dry substances by the plant is increased somewhat by the absorption of minerals and of nitrogen. At the time of ripening no loss of the ash constituents takes place through the roots into the soil. Erroneous conclusions are often drawn because of the dissolving action of atmospheric precipitation. Robertson's formula is not considered correct, for the experimental conditions are never the same. Comparatively low temperatures at the beginning of the growing season cause the first part of the curve to rise too slowly. Barley and mustard show too little growth, while oats, peas, and beans show too much. The difference in growth is probably accounted for by the different dissolving powers of the various roots on the difficultly soluble soil constituents.—*F. M. Schertz.*

2788. YOUNG, H. C., and C. W. BENNETT. Growth of some parasitic fungi in synthetic culture media. Amer. Jour. Bot. 9: 459-469. 4 fig. 1922.—Previous work on the food requirements of fungi is reviewed. The roles of the so-called essential chemical elements as

well as of calcium and zinc were studied in an attempt to produce a synthetic solution for parasitic fungi. Fungi were found to vary markedly in their requirements. Calcium was beneficial to most species, probably from its effect in correcting acidity, and it is evidently to be regarded as an essential element for fungi. Some species were stimulated by zinc, but in others this produced no effect. A proper balance of the inorganic constituents is very essential and can readily be obtained for any given fungus by the use of the 3-salt system.—The following organisms were used: *Fusarium oxysporum*, *F. batatas*, *F. radicola*, *Rhizopus nigricans*, *Aspergillus niger*, *Botrytis Allii*, *Phoma apiicola*, *Fusarium conglutinans*, *Cercospora Apii*, *C. beticola*, *Sclerotinia libertiana* (strain 1), *S. cinerea*, *S. libertiana* (strain 2), *Rhizoctonia Solani*, *Macrosporium sarcinaeforme*, *Sphaeropsis Malorum*, *Sterigmatocystis Violae*, *Vermicularia* sp., *Ascochyta Pisi*, *Colletotrichum lagenaria*, *Dothidella Quercus*.—E. W. Sinnott.

GROWTH, DEVELOPMENT, REPRODUCTION

2789. HOPKINS, E. F. The effect of lactic acid on spore production by *Colletotrichum lindemuthianum*. *Phytopathology* 12: 390-393. *Fig. 1-2*. 1922.—A strain which produced very few spores in neutral potato dextrose agar sporulated freely on this agar after the addition of 3 drops of a 50 per cent solution of lactic acid to each 20 cc. of agar.—B. B. Higgins.

2790. LEWIS, E. Yeast growth. [Rev. of: SLATOR, A. *Trans. Chem. Soc.* 1921: 115-119. 1921.] *Jour. Soc. Chem. Indust.* 40: 187R.-188R. 1921.—The reviewer stresses many of the facts set forth in the original as indicated below. The growth of yeast has phases: the quiescent or lag phase, the logarithmic phase of unrestricted growth, and the retarded phase. The amount of growth is dependent on the factors that retard growth. If the ratio of the constant of growth to the fermentative activity is constant, the yeast crop is proportional to the amount of sugar, if this is constant. CO₂ may be a limiting factor. The yield of yeast per unit amount of sugar is dependent on the amount of O₂ supplied. Much sugar is needed when there is little O₂. The important point in aerating is to remove the CO₂, not to supply O₂.—G. B. Ray.

2791. MITSCHERLICH, E. A., und FRANZ DÜHRING. Gefässversuche mit Erlen- und Fichtenpflanzen, 1920. [Pot culture experiments with seedlings of alder and pine.] *Zeitschr. Forst- u. Jagdw.* 53: 486-494. 1921.—In continuation of work described in the abstract following, small trees were grown in pots under controlled conditions to study the effects of different factors. The effect of varying volumes of soil and varying concentrations of nutrient solution upon the growth of yearling pine trees was expressed by the equation

$$y = 145 (1 - e^{-2.4c}) (1 - e^{-0.18b}) - 8$$

in which c = concentration of nutrient solution and $b = \frac{1}{8}$ the volume of soil; 8 = original weight of the pine seedling. A concentration of 1.5 per cent nutrient solution was somewhat harmful to the trees, otherwise the observed and calculated values agreed very well.—The growth of young alder trees was observed in relation to amounts of water supplied and to the volume of soil in which the seedlings were grown. With constant water content the trees made better growth, corresponding to increased volume of soil. With constant amounts of soil, however, the trees did not grow better with increased amounts of water. The forest trees make better use of the water which stands in the uppermost layers of the soil, because smaller amounts of energy are used for root growth and for water conduction in the plant.—The effect of the applications of Thomas slag upon the growth of oats and pine seedlings was found to be beneficial up to a certain point. The increased growth of the seedlings was a logarithmic function of the amount of Thomas slag applied and was expressed by the equation

$$\text{Log } (A - y) = \text{log } (A - 6) - 0.33 (x - 0.9)$$

where A = maximum growth, y = growth attained when x grams of Thomas slag were applied. When the amount of soil for each tree and the amount of Thomas slag were used as variables the growth was expressed by the equation

$$y = 90(1 - e^{-0.33(x+0.9)}) (1 - e^{-0.15z1}) - 6$$

The laws of growth exemplified in the equations have a general application to plant growth and afford a logical method of studying the effects of various agencies on growth.—H. S. Reed.

2792. MITSCHERLICH, E. A., FRANZ DÜHRING, und SUSANNE VON SANCKEN. *Das Wirkungs-gesetz der Wachstumsfaktoren*. [The law of growth factors.] *Landw. Jahrb.* 56: 71-92. 1921.—Realizing the inconsistencies of Liebig's Law of the Minimum, the senior author has proposed a more comprehensive law of growth factors which assumes that the magnitude of the plant's growth depends not on one, but on all factors influencing growth. The yield increases according to this law of growth with each single growth factor only when this factor is not too near the limiting value. Any growth factor may, within limits, replace another in its power to increase plant yields, without requiring any assumption that one factor may perform the specific function of another in the plant.—If all the conditions were optimal a certain maximum yield, A , would be obtained. If some necessary factor can be deficient there is a corresponding shortage in the yield, but if the amount of the factor be increased the yield is also increased. The rate at which the yield is increased by a small increase of the factor is proportional to its departure from the maximum yield and is expressed by the equation

$$\frac{dy}{dx} = (A-y)k \quad \text{I}$$

A = maximum yield, y = yield obtained when x = amount of factor present, and k = constant. Upon integration I becomes

$$\log (A-y) = C-kx \quad \text{II}$$

When $x=0$, $y=0$; therefore $\log A=C$, and

$$\log (A-y) = \log A - kx \quad \text{III}$$

This equation affords no evidence of the existence of a Minimum in Liebig's parlance.—Equation III may be written

$$\frac{A-y}{A} = e^{-kx}, \text{ or} \\ y = A(1-e^{-kx}) \quad \text{IV}$$

If 2 dependent factors, x , and x_2 , acting jointly produce a yield of A , the equation will be

$$y = A_1 (1-e^{-k_1x_1}) (1-e^{-k_2x_2})$$

or finally for all growth factors,

$$y = A_{\max.} (1-e^{-k_1x_1}) (1-e^{-k_2x_2}) (1-e^{-k_3x_3}) \dots \quad \text{V}$$

This equation is a mathematical expression of the law above stated. This law is applicable to all factors which exert an influence upon the yield of plants. Internal and external factors of growth may be recognized; the former are hereditary, the latter are climatic and edaphic. Man may influence to some extent the factors concerned with water and with nutrients. The authors have shown that the relative value of 2 fertilizer materials containing the same nutrient must be constant. If 2 materials produce the same maximum yield, A , then each contains the same growth factor. If the constant of one material equals k_1 and that of the other equals k_2 , then in order to produce the same yield, y , one must use an amount, x_1 , of the first material, and an amount, x_2 , of the second material. Therefore,

$$\log (A-y) = \log A - k_1x_1; \log (A-y) = \log A - k_2x_2.$$

By subtraction, $k_1x_1 = k_2x_2$, or, $\frac{k_1}{k_2} = \frac{x_2}{x_1}$

The amounts of the fertilizer to be applied must therefore be inversely proportional to their effects on growth. The law of growth factors gives an exact valuation of the total fertilizer materials and therewith a physiological basis which may throw light on the possibilities of a plant analysis for determining the fertilizer requirements of soils.—Numerous experiments are reported which show the validity of the law of growth factors.—Various plants were grown under differing light intensities. Their growth curves followed the equations:

$$\text{oats (grain and straw), } \log (110-y) = 2.0414 - 2.5 (i - 0.15)$$

$$\text{peas (grain and straw), } \log (42-y) = 1.6232 - 2.5 (i - 0.15)$$

$$\text{peas (grain), } \log (21-y) = 1.3222 - 2.5 (i - 0.177)$$

The value of k in each case was 2.5.—The effect of water upon growth was observed in sand and soil cultures. Plants in sand cultures were irrigated with Tollen's solution. Values obtained were:

vetch in sand,	$\log (35-y) = 1.5441 - 0.000515 w$
oats in sand,	$\log (130-y) = 2.1139 - 0.000515 w$
vetch in garden soil,	$\log (69-y) = 1.8388 - 0.000515 w$
carrot in garden soil,	$\log (70-y) = 1.8451 - 0.000515 w$

The identity of the constant for the different plants in different soils is noteworthy. The author believes that the value of water as a growth factor is independent of the nature of both the plant and the physical character of the soil. By use of equation V, as suggested by Baule [see Bot. Absts. 12, Entry 823], it was shown that the effects of concentration of nutrients and of soil volume are amenable to mathematical treatment:

$$\begin{aligned}\text{oats, } y &= 130.4 (1 - e^{-0.135x}) (1 - e^{-0.24z}) \\ \text{peas, } y &= 340.0 (1 - e^{-0.135x}) (1 - e^{-0.24z})\end{aligned}$$

where x = volume of the soil and z = concentration of nutrients. From this and other data the author believes it makes no difference what plant is used for fertilizer experiments. The fact that each fertilizer material possesses a specific physiological nutrient value makes possible an exact evaluation of fertilizer materials. This furnishes a physiological basis for chemical soil analysis, since it is possible to determine quantitatively the effect of various factors on the yield. It is possible, where irregularities occur, to study the physiological reactions and the effect of different sorts of soils on the fertilizer materials and to pursue the problems further by chemical methods. [See also Bot. Absts. 12, Entry 2795.]—*H. S. Reed.*

2793. PRESCOTT, J. A. The flowering curve of the Egyptian cotton-plant. *Ann. Botany* 36: 121-130. 7 fig. 1922.—The summation flowering curve (total flowers per plant up to a certain mature stage of growth) is worked out for the Egyptian cotton-plant. The methods and equations in obtaining it are given, together with an explanation of its significance in agricultural experiments.—*Marian A. Griffiths.*

2795. RIPPEL, A. Die gesetzmässige Erforschung von Reaktionsgleichgewicht (Produktionskurve) und Reaktionsgeschwindigkeit (Wachstumskurve) bei den höheren Pflanzen. [The quantitative investigation of the amount and rate of growth of higher plants.] *Jour. Landw.* 70: 9-44. 1922.—This is a résumé of recent work in Germany on the quantitative study of plant growth. Studies are based on the assumption that with a knowledge of all pertinent conditions it is possible to obtain an exact mathematical expression of growth. In dealing with plants it is usually necessary to be content with a practical method for a comparative study of the growth-affecting factors, and later make such refinements as the material may require.—The yield-curve expresses the quantitative result of graded differences in concentration of nutrient substances, other factors remaining constant. The comprehensive law applicable to such phenomena is the law of mass action. The growth-curve deals with reaction-velocities and is essentially a problem in dynamics. The growth reaction behaves as an autocatalytic reaction which is catalyzed by one of the products of the reaction. The value of these views lies in the concept that plant growth in its entirety is an orderly process, capable of quantitative study. This concept has an evident difficulty, namely that the complicated interplay of all possible processes of plant growth should conform to a single physical-chemical law. However, the difficulty does not actually exist because the concept applies, not to the many single physiological processes which operate in the plant, but to their summation.—The production curve is expressed by Mitscherlich [see Bot. Absts. 12, Entry 2792] as follows:

$$\log (A-y) = \log A - kx.$$

The author discusses the relation of this equation to the action of heat, light, and other factors, and he gives a lengthy critique of the fluctuations observed in the value of k , the

so-called "efficiency factor." He holds that Mitscherlich's equation is a full, quantitative expression of Liebig's Law of the Minimum. The equation expresses the quantitative relations between yield and minimum factor. Liebig opposed the idea that when several factors were increased from a minimum to a higher value, without changing their proportionality, a higher plant yield would result. Mitscherlich's investigations afford evidence, however, that this is true. It may also be possible that an increase in the amount of the sole minimum factor might cause a profound mobilization of other substances in the plant.—The curve of growth may be expressed by several equations. The author discusses those proposed by Robertson and by Baule. The external environment has no such influence upon the course of the growth cycle of a species as one might expect on *a priori* grounds. It has been shown that the value of the constants is quite invariable for a given species when grown by various experimenters, in different regions and in different seasons. Different species, however, have very different growth constants.—Since all growth curves eventually become horizontal, it is evident that some limiting factor is operative. The limiting factor may be within the plant or within the environment. The limiting factor is usually operative from the initial stages of growth.—The production curve rests on the law of chemical mass action, although it is impossible to express total yield with all the variable factors involved. If the factors are taken separately, however, it is not difficult to demonstrate their quantitative relations. The assimilation of CO_2 is a case in point.—The growth curves have been shown to resemble those of autocatalysis, as one might expect from the manner of cell-division. The absolute height of the curve is determined by the external factors operative, and the variable factor is time. The flattening of the curve is undoubtedly due to the action of inner, limiting factors, which must be different from those of the production curve. A certain correspondence between the 2 may exist, however, since in the senescent protoplasm absorption and assimilation gradually cease.—*H. S. Reed.*

2796. ROBBINS, WILLIAM J. **Cultivation of excised root tips and stem tips under sterile conditions.** Bot. Gaz. 73: 376-390. Fig. 1-4. 1922.—Apical meristems of peas, corn, and cotton excised from seedlings were successfully grown under sterile conditions in a modified Pfeffer's solution plus glucose. Glucose proved uniformly superior to levulose. With glucose, however, the growth is of the etiolated type, indicating "that it is not an absence of available carbohydrate which causes the stem elongation and small leaf development of plants grown in the dark." Concerning his experiments with tips excised from culture material the writer states: "When the excised root tips of corn are grown for ten days or two weeks in the dark in a solution containing glucose and mineral salts, and the tip is then cut off and transferred to a fresh solution of the same type, the amount of growth in the 2nd period is less than in the 1st, and ceases in the 3rd period." [See also following entry.]—*B. W. Wells.*

2797. ROBBINS, WILLIAM J. **Effect of autolized yeast and peptone on growth of excised corn root tips in the dark.** Bot. Gaz. 74: 59-79. Fig. 1-8. 1922.—In sterile Pfeffer's solution plus 2 per cent glucose, in the dark, excised corn root tips grow much less rapidly than those attached to the grain. When the excised root tips are grown under such sterile conditions for about 2 weeks and the tips then severed and transferred to fresh solutions at intervals: "(a) growth stops in the third period; (b) the addition of peptone or autolized yeast permits the root tips to grow for 4-6 periods; (c) a concentration of 200 ppm. [parts per million] of gelatine, 100 ppm. of creatinine, 79 ppm. of glycocoll, 50 ppm. of asparagin, of the corn extract used show no beneficial effect; (d) in Pfeffer's solution lacking nitrates and containing 2 per cent glucose a little less total growth is made than in Pfeffer's solution containing nitrates and 2 per cent glucose; (e) approximately 400 ppm. of peptone is more efficient than 200 ppm; (f) autolized yeast is more beneficial than peptone; (g) the beneficial effect of autolized yeast does not appear in the first period of growth; (h) concentrations of 10, 40, 80, 200, 400 and 800 ppm. of autolized yeast (equivalent in dry matter to about one-third the concentrations given) show no marked difference in their beneficial effect, especially in the early periods; (i) the higher concentrations of yeast evidence a somewhat greater beneficial effect in the later periods than the lower concentrations." Comparisons are also made, as to the extent of

growth, between excised and undisturbed root tips in media with and without autolyzed yeast. It is further shown that root tips act as individuals and that growth of the primary root tip depresses that of secondary roots. [See also preceding entry.]—*B. W. Wells.*

MOVEMENTS OF GROWTH AND TURGOR CHANGES

2798. BIRCH, JOHN J. Important movements of plants. II. *Amer. Bot.* 28: 107-112. 1922.—This is a summary of the positions assumed by growing tips of roots and stems.—*S. P. Nichols.*

2800. CHOLODNYJ, N. Zur Theorie des Geotropismus. [The theory of geotropism.] *Beih. Bot. Centralbl.* I Abt. 39: 222-230. 1922.—At present no entirely satisfactory theory of geotropism can be formulated, only a working hypothesis may be presented.—The microsomes move easily in the cytoplasm. They usually possess a higher specific gravity than the surrounding cytoplasm. They carry on their outer surfaces a negative electric charge which they give out in their movement towards the anode. In the plasma of positively geotropic cells the microsomes with a specific gravity less than that of the surrounding fluids prevail. As they move upward they produce a corresponding electrical force.—More work is needed on the role of the ion as well as a thoroughgoing cytological investigation of changes due to gravity. Knowledge of the effect of electricity on the geotropic reactions is also needed. Such investigations might show what is necessary to establish or correct this hypothesis.—*L. Pace.*

2801. JACCARD, PAUL. Sur le mecanisme du redressement geotropique de la tige des arbres. [The mechanism of geotropic readjustment of the trunks of trees.] *Rev. Gén. Bot.* 34: 385-398, 433-441, 481-488, 529-537. *Fig. 1-4.* 1922.—The author tries to establish the determinism of reactions generally considered as tropisms having some useful significance for the species or the individual.—Supposing that the normal form of growth of woody plants, that of trees in particular, is the result of antagonistic forces in equilibrium oriented parallel either to the direction of gravity or to that of optimum light, all deviations from the normal position of equilibrium provoke a readjustment, either a photo- or geotropic reaction which necessitates mechanical work.—One may investigate whether the mechanical forces brought into play during the readjustment of a trunk, for example, are the result of unequal activity of growth due to geotropic excitation perceived at the tip. It is here assumed that the unequal growth is produced in a way to affect the earlier form of static equilibrium with minimum material. On the contrary, the normal form of equilibrium being disturbed, the tension-compression thus produced may cause the unequal activity of the cambium and the eccentric growth which results. This indicates the trend of the author's argument, a detailed review of which cannot be given.—It is believed that the growth acceleration is essentially determined by the reaction to the mechanical effect, due to gravity and engendered by photo- and geotropic orientation. Further it is pointed out that the "finalists" do not deny the influence of mechanical actions on growth in thickness, but admit it only as a complementary claim, as a factor capable of accentuating, enfeebling, or neutralizing the effects of geotropic stimulation. This mixture of "finalism" and "causalism" recalls strongly the concession made by vitalism to physico-chemical determinism in the domain of physiology.—Conformable to the results of his experiments the author believes that the majority of cases of unequal rapidity of growth in thickness of leaning trunks and branches may be explained by the antagonistic action of tension-compression and by the influence of the acceleration or retardation that these forces exert on the activity of the cambium.—The importance of the forces of orientation in growth cannot be overestimated. Their morphogenic influence is affirmed from the beginning of segmentation: it dominates all the karyokineses, and the analogy which these phenomena present between organic polarity and magnetic or electric polarity is not fortuitous.

The difference in behavior of the 2 poles of growth of vegetation exposed to gravity is not stranger than that which distinguishes the magnetic poles of opposite names. The different properties of twigs and roots is only possible as a consequence of this general and original polarity which they carried in the embryo; in the case of twigs and radicle, Letellier has already established it, by a difference of specific gravity which constitutes without doubt one of the immediate reasons for their final differentiation. It is not without interest to remark that in a general way the radicle, having turned from the side of the micropyle, is found from the point of view of its osmotic nutrition in different condition from that of the plumular pole. Without undervaluing the role of heredity, this memory of repeated reactions which are carried out by a specific structure, one cannot avoid thinking that an equal difference might possibly be the first cause of the character of polarity which became accentuated in the repetition.—As to the morphogenic influences which govern nutrition and growth it is necessary to determine the part which they play, thus: (1) the forces of orientation, gravitation, radiation, and to a lesser extent those of chemical affinity, and electric and magnetic currents; (2) osmotic forces which play a part in nutrition; (3) mechanical forces engendered by growth and resulting from gravity; and (4) catalytic forces in which are included enzymic action and the influence of hormones, these last sometimes considered as agents of transmission governing the correlations of growth.—The author does not deny that a number of phenomena such as concern floral biology, the dissemination of seed or the transport of pollen by the aid of insects adapted to the operation, can only be explained in a satisfactory manner by mechanical or chemical actions; therefore in this study it is held that general characteristics of form, type of symmetry, and the deviations which plants undergo are under the influence of morphogenic factors, the dominant forms of which are gravity and light.—*J. C. Gilman.*

2802. RICHME, H. *Sur l'élongation des racines.* [On the elongation of roots.] *Compt. Rend. Acad. Sci. Paris* 174: 880-881. 1922.—The fact that the stem of a horizontal plant turns up and the root turns down makes it seem that the reaction of these 2 structures to the same stimulus is exactly opposite. The experiments here reported are, however, interpreted as showing that they both respond in the same way. It is found that if a root is pricked with a needle it curves during the 1st hour throughout a distance of about 15 mm. If the root is in the normal vertical position this curvature will direct the tip of the root horizontally. This curvature is a modification of internal tensions and is not due to gravity. It will later turn down again, causing the root to assume an elbow form. If, however, the root be pricked when in a horizontal position the curvature always occurs upward at first, just as the stem always grows upward when in a horizontal position. It has previously been shown that if the region of cell elongation of a stem be injured, the stem turns downward; now it appears that if the region of cell division of a root is injured, the root curves upward. It is therefore concluded that the region of cell elongation responds to the stimulus of gravity by causing the organ to bend downward, and the region of cell division responds to the same stimulus by causing the organ to curve upward. Thus it appears that the region of cell division governs the direction of the stem, and the region of cell elongation controls the direction of the root.—*C. H. Farr.*

REGENERATION

2803. WEISS, FREEMAN. *Quantitative relations of regeneration.* [Rev. of: (1) REED, H. S. *Correlation and growth in the branches of young pear trees.* *Jour. Agric. Res.* 21: 849-876. Pl. 1. 1921 (see Bot. Absts. 11, Entry, 793); (2) LOEB, JACQUES. *The quantitative basis of the polar character or regeneration in Bryophyllum.* *Science* 54: 521-522. 1921 (see Bot. Absts. 11, Entry 801). *Bot. Gaz.* 73: 496-497. 1922.—The reviewer thinks that progress toward solving the problem of dominance of the apical part of the shoot "must wait on more adequate information concerning the anatomical relations of the apical and lateral buds and of tissue changes in regeneration." He mentions the following as subjects of further investigation: the comparative efficiency of the apical vascular supply and that of lateral buds; the relative age of terminal and lateral buds; the axial gradient in cases of indeterminate growth and those of limited apical growth; presence of cytoplasmic connections; the effect of callus

deposition in the sieve tubes and lignification changes in the phloem as these are related to a possible gradient in transport efficiency from apex to base.—*B. W. Wells.*

TEMPERATURE RELATIONS

2804. GAIN, EDMOND. *Température ultra-maxima supportée par les embryons d'Helianthus annuus L.* [The ultra-maximum temperature endured by embryos of *Helianthus annuus*.] *Compt. Rend. Acad. Sci. Paris* 174: 1031-1033. 1922.—Seed of sunflower survive a temperature of 85°C., though many lose the power of germination. Gradual drying and heating, alternating with periods of cooling or of constant temperature for many hours, or even days, permits of a considerable raising of this temperature limit. It was found that by heating in successive steps with stops at 80 and 110°C. temperatures as high as 135-150°C. may be reached without destroying the viability of the seed. The highest point reached in these experiments was 155° preceded by 15 minutes at 140°C. As high as 52 per cent of the seed which had been raised to 150°C. germinated. Varieties are found to differ in resistance to heat.—*C. H. Farr.*

RADIANT ENERGY RELATIONS

2805. LUCKIESCH, M. *Ultraviolet radiation. Its properties, production, measurement and applications.* 270 p., 12 pl. D. Van Nostrand Co.: New York, 1922.—The title indicates the general scope of this work. One chapter is devoted to some effects upon living organisms and protoplasm, and another discusses photochemical effects.—*B. M. Duggar.*

2806. STOKLASA, J. *Über die Radioaktivität des Kaliums und ihre Bedeutung in der chlorophyllosen und chlorophyllhaltigen Zelle. I.* [Radioactivity of potassium and its significance in chlorophyll-free and green cells.] *Biochem. Zeitschr.* 108: 109-139. 1920.—The percentage of germination and the rate of growth of all plants investigated was increased by radioactive minerals, stones, earths, and natural waters.—Potassium compounds showed the same stimulation, the activity being attributed to the β -rays of potassium.—*H. D. Hooker, Jr.*

TOXIC AGENTS

2807. PLOTHO, O. VON. *Der Einfluss kolloidaler Metallösungen auf niedere Organismen und seine Ursachen.* [The influence of metals in colloidal solution on lower organisms.] *Biochem. Zeitschr.* 110: 1-32. 1920.—Bacteria, fungi, algae, protozoa, and some higher plants were treated for 1-4 days at 15-20°C. with hydrosols containing 0.003 per cent silver or gold. Absorption of the metal occurred in none of the silver solutions and in none of the gold solutions to which protective colloids were added. Gold absorption took place from weakly alkaline unprotected solutions in all species of *Aspergillus* and *Penicillium* tried, in *Botrytis vulgare* and in *Paramaccium* sp. It never occurred in *Mucor mucedo*, *Monilia variabilis*, *Dematium pullulans*, *Oidium lactis*, or yeast; nor in any of the bacteria, algae, and higher plants treated; nor in amoebae. Gold storage was accompanied by no harmful effects to the fungi other than a delay in the initiation of fructification and a slight retardation of growth in length of the hyphae. It occurred to a greater extent in living than in dead material. The membrane alone was concerned, but no chemical combination with the gold occurred, the metal remaining in the elemental state. Variations in concentration and temperature had no significant effect on gold storage.—*H. D. Hooker, Jr.*

2808. PLOTHO, OLGA, VON. *Der Einfluss kolloidaler Metallösungen auf niedere Organismen und seine Ursachen.* Dissertation. 8 vo, 58 p. Gottingen, 1920.—[See preceding entry.]

2809. RIDEAL, S., and E. K. RIDEAL. *Chemical disinfection and sterilization.* 8 vo, viii + 314 p. Edward Arnold & Co.: London, 1921.—In the introduction the authors write briefly of the relation of microorganisms to human welfare and of the development of methods of disinfection and antisepsis. The remainder of the book may conveniently be divided into

2 parts. Chapters 2-8 treat such topics as disinfection of air, sterilization and preservation of food, sterilization of water, public disinfection, personal and internal disinfection, non-bacterial parasites, and wood preservation. The 6 chapters of the 2nd part treat of the numerous organic and inorganic substances possessing germicidal properties, giving their origin, uses, structural formulae, pertinent physical and chemical characters, trade names, and relative efficiency as germicides. Numerous citations to current literature are given.—*S. G. Lehman*.

2810. STOKLASA, J. Influence du sélénium et du radium sur la germination des grains. [The influence of selenium and of radium on the germination of seeds.] Compt. Rend. Acad. Sci. Paris 174: 1075-1077. 1922.—The seeds of various cereals as well as of *Vicia faba* and buckwheat were tested. Selenium salts in extreme dilutions are found to have a toxic effect, which later changes to a stimulation of growth. All species exposed to radium emanations germinate better. It is also found that radioactivity neutralizes in a large measure the injurious effect of selenium.—*C. H. Farr*.

SOIL SCIENCE

A. G. McCALL, *Editor*

(See also in this issue Entries 2228, 2231, 2232, 2235, 2238, 2242, 2244, 2245, 2248, 2250, 2255, 2258, 2259, 2267, 2268, 2272, 2273, 2278, 2280, 2347, 2383, 2464, 2469, 2483, 2493, 2737)

2821. BEAR, FIRMAN E. Nitrogen economy in soils. Jour. Amer. Soc. Agron. 14: 136-152. 1922.—Temperature, rainfall, soil reaction, the cropping system, fertilizer treatment, and soil texture are some of the factors which cause the point of equilibrium between nitrogen income and outgo in soils to vary. The author gives a general discussion of the subject.—*F. M. Schertz.*

2822. BIZZELL, JAMES A. Disappearance of nitrates from soil under timothy. Jour. Amer. Soc. Agron. 14: 320-326. 1922.—The addition of NaNO_3 to timothy sod in early spring is followed by a rapid disappearance of the nitrate from the upper 8 inches of soil; this disappearance is due only in part to the absorption of nitrogen by the growing crop. The nitrate unaccounted for evidently has been utilized by various soil organisms and is therefore transformed into ammonia or some organic combination.—*F. M. Schertz.*

2823. BROWN, P. E. Soil types as a basis for soil investigations. Jour. Amer. Soc. Agron. 14: 198-206. 1922.—A plea is made for accurate scientific classification of the soils used in experimental work.—*F. M. Schertz.*

2824. DAVIS, R. O. E. The interpretation of mechanical analysis of soils as affected by soil colloids. Jour. Amer. Soc. Agron. 14: 293-298. 1922.—Mechanical analysis does not furnish a true picture of the quantitative distribution of the various sized mineral particles in the soil. The silt and clay groups of mineral particles are made up in part of colloidal material. A water vapor absorption method is described by means of which the colloids present in the silt and clay groups may be determined.—*F. M. Schertz.*

2825. DEIGHTON, THOMAS. Some investigations on the electrical method of soil moisture determination. Jour. Agric. Sci. 12: 207-230. Fig. 1-6. 1922.—After briefly reviewing previous work on the electrical method of soil moisture determination, the author describes further work. "It is concluded that the method gives the mean water content of a volume of soil somewhat greater than a sphere whose poles are the electrodes. Certain resistance-moisture curves obtained in the laboratory are discussed and it is concluded that while at water contents above 10 per cent, the relation found by the American investigators holds good; viz., that the resistance varies inversely as the square of the moisture content; at lower water contents discontinuities appear in the curve. These discontinuities are reversed in the case of artificial mixtures not containing colloids." A tentative explanation of these phenomena is given.—*V. H. Young.*

2826. DEMOLON, A. Oxydation microbienne du soufre. [Sulphur oxidation by bacteria.] Compt. Rend. Congrès Assoc. Française Avancement Sci. 45: 1386-1387. 1921.—Bacteria which oxidize sulphur are found in all soils, but are more abundant in soils rich in humus. The author confirms the parallelism between sulphofication and nitrification.—*J. Dufrenoy.*

2827. EATON, SCOTT V. **Sulphur content of soils and its relation to plant nutrition.** Bot. Gaz. 74: 32-58. 1922.—The author used Hart and Peterson's sodium peroxide method in his sulphur determinations. The phosphorus content was also determined, using the magnesium nitrate method recommended by the Association of Official Agricultural Chemists. The author's summary follows in part: The Alabama, Maryland, and Oklahoma soils analyzed are low in sulphur, phosphorus, and organic matter—the phosphorus being not much greater in amount than the sulphur. The soils of the central states are better supplied with these 3 materials and contain decidedly larger amounts of phosphorus than of sulphur. The Chicago soils have a fairly good content of phosphorus, and a rather high content of sulphur and organic matter. The sulphate-sulphur content of the Chicago soils is high, but this accounts for little of the total sulphur, since the greater part is contained in the large amount of organic matter present. Judging from the results obtained and the work of other investigators, sulphur fertilization should prove quite generally beneficial on the Atlantic coast and the Gulf coast, but of doubtful value in the central states. Soils of a high organic-matter content, such as the Chicago soils, may not need sulphur fertilizers except for high sulphur-using crops. No definite conclusions can be drawn from the data as to the relation of sulphur to chlorophyll development, since any effect upon the chlorophyll may come about through the effect of the sulphur in increasing the nitrogen content of the plants. Flowers of sulphur and sodium sulphate, containing the same amount of sulphur as 100 pounds of gypsum per acre, and gypsum at the rate of 500 pounds per acre caused increased dry weights of sweet corn of 35-66 per cent. Larger amounts of flowers of sulphur and sodium sulphate gave no further increases. The corn soil fertilized with sulphur had a higher moisture content than the controls, the excess in the case of the gypsum series amounting to 5 per cent.—B. W. Wells.

2828. EMERSON, PAUL, and JOHN BARTON. **The potassium-nitrogen ratio of red clover as influenced by potassic fertilizers.** Jour. Amer. Soc. Agron. 14: 182-192. 1922.—The application of various forms of fertilizers on pot-culture tests of a Miami silt loam soil leads to the following conclusions: The amount of K absorbed by red clover varies with the treatment of the soil. Applications of manure, acid phosphate, or combinations of both increase the solubility of the soil K as indicated by the amount taken up by the plant. K is taken up in larger amounts from kainit than from either KCl or K_2SO_4 . Lime as $CaCO_3$ applied to an acid soil apparently has no effect upon the solubility of native soil K, but may possibly over-stimulate nitrate production. Applications of lime slightly widen the K-N ratio but manure or acid phosphate or both in the presence of lime narrows the ratio.—F. M. Schertz.

2829. EMERSON, PAUL, and ROLAND D. FLETCHER. **The effect of Sudan grass on the biological processes in the soil.** Jour. Amer. Soc. Agron. 14: 235-241. 1922.—Sudan grass, a heavy feeder, does not materially reduce the crop-producing power of the soil; neither does it influence the soil to respond favorably to the application of common fertilizers. Sudan grass lowers the total bacterial content of the soil on which it grows but apparently does not interfere with the physiological activities of the microorganisms which are concerned in the production of available plant food. Organisms concerned in the transformations of nitrogen in the soil are favorably influenced by the growing of Sudan grass. This effect is particularly noticeable on the crops which follow.—F. M. Schertz.

2830. GREAVES, J. E. **The influence of irrigation water on the composition of the soil.** Jour. Amer. Soc. Agron. 14: 207-212. 1922.—The intelligent use of irrigation water requires knowledge of the chemical, physical, and biological properties of the soil, together with a knowledge of the composition of the water and its influence upon the chemical, physical, and biological changes going on in the soil.—F. M. Schertz.

2831. HUTCHESON, T. B., and T. K. WOLFE. **The effect of fertilizers on the germination and bacterial development of inoculated soybean seed.** Jour. Amer. Soc. Agron. 14: 284-286. 1922.—Results indicate that fertilizers at the rate used in these experiments when applied to a sandy loam soil in direct contact with soybean seed had no appreciable detrimental effect on

the germination of the seed or on the development of nodules on the roots of the plants.—*F. M. Schertz.*

2832. K[UYPER?], J. **De waarde van stikstof in verschillende kunstmeststoffen.** [The value of nitrogen in different fertilizers.] *Arch. Suikerindust. Nederland-Indië* 30: 733-734. 1922.—A critical summary is presented of an article in *Chemische Industrie* (p. 294, 1922) in which a list of prices is given showing the value of nitrogen in several fertilizers as determined by the German Government. It seems that in many places Chili saltpeter is still regarded as better than ammonium sulphate; but in Java, the 2 are regarded as about equal, with a slight prejudice in favor of ammonium sulphate.—*Peter J. Klaphaak.*

2833. LYON, T. L. **Intertillage of crops and formation of nitrates in soil.** *Jour. Amer. Soc. Agron.* 14: 97-109. 1922.—Experiments on a silty clay loam soil at Ithaca, New York, covering a period of 2 years, are recorded, and the effects of cultivating, scraping, and mulching are discussed. Evidence presented favors the assumption that the nitrate content of the cultivated plats is higher than that of the scraped plats because of the aeration produced by the stirring.—*F. M. Schertz.*

2834. ROBINSON, GILBERT WOODING. **A new method for the mechanical analysis of soils and other dispersions.** *Jour. Agric. Sci.* 12: 306-321. *Fig. 1-4.* 1922.—The author discusses the expression of mechanical composition of soils by curves and suggests that a convenient representation is obtained by showing summation percentage as a function of logarithm of settling velocity. The effect of a gel coating is to reduce the settling velocity of particles, the reduction being a simple function of the thickness of the gel coating. A method of obtaining the mechanical composition of a soil or clay from determinations of the concentration of a settling suspension for different ratios of depth to time is described. A shortened method of mechanical analysis is described which gives results in good agreement with the present standard method, and the effect of various modifications in conditions of working is discussed. An examination is made of the concentration gradients in the settling column of a suspension, and it is shown that below the first few centimeters the change in concentration with depth is very gradual.—*V. H. Young.*

2835. ROBINSON, GILBERT WOODING. **Note on the mechanical analysis of humus soils.** *Jour. Agric. Sci.* 12: 287-291. 1922.—Defects of the various methods in vogue for breaking down organic matter in soils preliminary to mechanical analysis are discussed. The use of a neutral substance such as H_2O_2 proved to be satisfactory. Humus soils treated with H_2O_2 gave considerably larger yields of clay and the results appear to more nearly represent the actual constitution of the soil than those obtained from other treatments.—*V. H. Young.*

2836. SALISBURY, E. J. **The soils of Blakeney Point: A study of soil reaction and succession in relation to the plant covering.** *Ann. Botany* 36: 391-432. *Pl. 15, 5 fig.* 1922.—As the dune systems grow older they exhibit a diminution of carbonates and an increase in organic content. These changes are the result of leaching and of augmentation of the plant covering. They are accompanied by a change from an appreciable alkaline condition to a marked acidity, and are correlated with the succession in the vegetation. There is a tendency on the older banks to develop an acid-tolerant type of vegetation. The H-ion concentration varies not only with the degree of leaching but also with the source of the organic material and the phase of its decomposition. The organic material is mainly responsible for the water capacity of dune soils, and in conformity with this the roots of ephemerals tend to occupy the upper layers where the humus is most abundant. The shingle banks show a similar sequence in reaction, organic content, and water content, as is evidenced by a study of shingle laterals of successive age. Floristic lists of these are given. The salt-marsh phases also show indications of increasing organic content, but in these the most important edaphic factor is the duration and frequency of tidal inundation.—*Roy Hansen.*

2837. TOCHER, J. F. **The citric solubility of mineral phosphates.** Jour. Agric. Sci. 12: 125-143. 1922.—Citric solubility is a purely empirical standard for testing mineral phosphates and is of little value in determining their actual value as fertilizers. The author has carried out carefully controlled analytical experiments on citric solubility and decides that it may to a certain degree be a measure of (1) the fineness of grinding, (2) the presence of alkaline substances in fertilizers approximately of the same composition and ground to the same degree of fineness, (3) the presence or absence of fluorides as well as alkaline substances in slags, and (4) the differences in the constitution of the phosphatic compounds in finely ground fertilizers containing approximately the same proportions of extraneous substances. The author concludes that the only practical tests of the value of phosphatic fertilizers from the agricultural standpoint are: (1) total phosphatic content; (2) degree of fineness of grinding; (3) freedom from injurious substances inhibiting plant growth.—V. H. Young.

2838. VINSON, A. E., and C. N. CATLIN. **Determination of the swelling coefficient of dry soils when wetted.** Jour. Amer. Soc. Agron. 14: 302-307. 1922.—Different soils show marked differences in the rate of swelling, the rate being seriously modified by chemical treatment. An auxograph with a clock giving 1 revolution of the drum in 15 or 20 minutes is recommended as most suitable for studying the rate of swelling.—F. M. Schertz.

2839. WHITING, ALBERT L., and WARREN R. SCHOONOVER. **Nitrate production in field soils in Illinois.** Illinois Agric. Exp. Sta. Bull. 225. 21-63. 1920.—The influence of soil treatment, cropping systems, and time of year on nitrate production is shown. A comparison of green and stable manure during these tests favors the former. Farm practices which reduce the loss of nitrogen by leaching and also the periods of greatest nitrogen utilization are discussed. The data reported are the result of 4 years' work.—O. H. Sears.

2840. WHITTLES, C. L. **A note on the classification of soils on the basis of mechanical analyses.** Jour. Agric. Sci. 12: 166-181. Fig. 1-11. 1922.—Various methods in vogue for classifying soils on the basis of mechanical analyses are discussed and a graphic method is proposed. A bibliography of 58 titles is appended.—V. H. Young.

2841. ZÖRNER, HANS. **Die Bewässerungswirtschaft im Lichte der landwirtschaftlichen Betriebslehre unter besonderer Berücksichtigung der deutschen Verhältnisse.** [Irrigation management in the light of agricultural economy, with special reference to German conditions.] Landw. Jahrb. 57: 605-665. 1922.—A detailed study of the economy of irrigation is presented under 7 general headings: (1) Natural factors in irrigation; relation between climate and irrigation, soil type and irrigation, type of cultivated plant and irrigation, and distribution of irrigation systems in the world under the influence of natural conditions. (2) Economic factors in irrigation; purpose of irrigation, costs, and rents in irrigation. (3) Suitable amount of irrigation. (4) Relation between artificial fertilizers and irrigation. (5) Organization of irrigation in relation to horticultural and field crops. (6) Influence of irrigation on the other branches of agriculture. (7) Irrigation management in Germany.—S. A. Waksman.

TAXONOMY OF VASCULAR PLANTS

(See also in this issue Entries 2239, 2247, 2315, 2385, 2392, 2411, 2436, 2437, 2450, 2506, 2512, 2514, 2558, 2666)

GENERAL

2842. COUTINHO, ANTONIO XAVIER PEREIRA. **Notas da flora de Portugal.** [Notes upon Portuguese flora.] 17 × 25 cm., 15 p. Allaud e Bertrand: Paris-Lisbon; Francisco Alves:

Rio de Janeiro, 1921.—The author states that this is the 5th and probably the final fascicle of notes supplementary to his Flora de Portugal, and that it is based upon (1) recent collections, and (2) revision of herbarium material made in the light of later monographic work. The list mentions 54 species, exclusively flowering plants, of which 12 species and 10 varieties or forms are additions to the Portuguese flora. There are also revisions of ranges, corrections of determination, etc. In all cases where additions or corrections occur, the author presents revisions of the keys which occur in his Flora de Portugal; especially keys to the cultivated forms of *Triticum*, to *Fumaria*, and to certain portions of *Viola*. *Silene transtagana*, *Dianthus brachyanthus* Bss. var. *nivalis* Wk. f. *Herminii*, *Hedysarum spinosissimum* L. var. *capitatum* (Desf.) f. *glabrescens*, *Lathyrus Cicera* L. β *subbijugus*, *Viola Kitaibeliana* R. & S. β *beirensis*, *Torilis neglecta* var. *triradiata*, *Lavandula pedunculata* Cav. γ *interrupta*, are proposed as new species, varieties, or forms, the authority being P. Cout. in all cases; *Atriplex foliosum* (Lk.) P. Cout. appears to be a new combination as a subspecies.—E. B. Chamberlain.

2843. HOUSE, HOMER D. A consideration of certain genera proposed by Ehrhart. Amer. Midland Nat. 6: 200-207. 1920.—Ehrhart, like Rafinesque, Sweet, and other writers, published genera without descriptions, merely by designating previously published species. In the present paper the author enumerates 18 genera which were proposed by Ehrhart in 1789, designates type species, and then lists some 80 species, mostly of the Cyperaceae, under the Ehrhartian generic names.—Sister M. Ellen.

2844. KOPS, JAN, F. W. VAN EEDEN, en L. VUYCK. Flora Batava. Afbeelding en Beschrijving der Nederlandsche Gewassen. [Flora of Batavia. Illustrations and descriptions of plants of Holland.] 410°-413° Aflevering. Pl. 2033-2048. Martinus Nijhoff: 's-Gravenhage, 1922.—The vascular plants illustrated in the present parts are *Rubus hirtifolius* Müll. & Wirtg., *R. sulcatus* Vest., *R. Lindleyanus* Lees, *Boltonia asteroides* L'Hérit., *Malva parviflora* L., *Calendula arvensis* L., and *Nicotiana affinis* Moore. The non-vascular plants included are: *Russula Linnaei* Fr., *Cortinarius cinnabarinus* Fr., *C. croceocoeruleus* Pers., *Tricholoma ionides* Bull., *Hygrophorus puniceus* Fr., *H. miniatus* Fr., *Lepiota odorata* Cool., *Mycena pelianthina* Fr. (*M. denticulata* Bolt.), *Polyporus adustus* (Willd.) Fr., *Flammula lenta* Pers., *Stereum sanguinolentum* A.&S., *S. frustulosum* Fr., *Hydnum acre* Quél., and *Trametes Pini* (Brot.) Fr.—J. M. Greenman.

2845. ROY, S. C. A preliminary classification of the wild rices of the Central Provinces and Berar. Agric. Jour. India 16: 365-380. 1921.—Many forms of wild rice [*Oryza*] occur in the Central Provinces. The grains fall before the ear is dead ripe and remain dormant in the soil till the next monsoon and so contaminate the rice crop leading to a considerable loss in yield. The method of pollination of wild rice is described and the occurrence of natural cross-fertilization has been proved by the examination of numerous cultures raised from single plants. Twenty-four types of wild rice are described and classified.—A. Howard.
